10 ml. of phthalate buffer of pH 4·0 (Wigglesworth[3]) containing varying concentrations of 'Gammexane', the control groups being tested in the presence of an equal quantity of kaolin alone. Of substances tested similarly, the following showed no protection: kerosene, refined liquid paraffin, cholesterol, tripalmitin and tristearin. Olive oil, soya bean oil, arachis oil and poppy-seed oil gave partial protection, while tributyrin, triolein, tricaprylin, tricaproin and tri-*n*-valerin showed in that order increasing ability to overcome the toxic effects of 'Gammexane'.

The results of further experiments indicate that this effect cannot be solely explained on the basis of the 'Gammexane' being removed from the aqueous phase by adsorption or solution into the triglyceride, but that the actual ingestion of the triglyceride is necessary. Thus refined liquid paraffin (in which 'Gammexane' is considerably more soluble than in water) does not decrease the toxicity at all (it is itself non-toxic under the conditions of testing). It is improbable that the quantity of 'Gammexane' adsorbed on the solid ingested affects the mortality when compared with the known large quantity of liquid circulated by larvæ[4]. Furthermore, pupæ of *A. ægypti* exposed to 1 p.p.m. of 'Gammexane' solution show no difference in mortality (reaching 100 per cent in 72 hours) whether in the absence or presence of triolein. The relative inefficiency of 'Gammexane' in killing pupæ is comparable to the complete lack of toxicity of D.D.T. towards pupæ[5,6,7]. It is clear that these compounds act more efficiently by ingestion than by contact in the case of mosquito larvæ.

EFFECT OF TRIOLEIN ON TOXICITY OF 'GAMMEXANE' FOR *C. lectularius*

Conc. of 'Gammexane' (mgm./sq. cm.)	Conc. of triolein (ml./sq. cm.)	Conc. of kerosene (ml./sq. cm.)	Observations after exposure of 1½ hr.	4 hr.	20½ hr.
0·05	0·00325	0·00325	Unaffected	Locomotor disturbance	All dead
0·05	0·0065	0	Unaffected	Unaffected	All dead
0·05	0	0·0065	Moribund or paralysed; unable to walk	Moribund or dead	All dead
0·1	0·0026	0·0026	Unaffected	Slight locomotor disturbance	All dead
0·1	0·0052	0	Unaffected	Slight locomotor disturbance	All dead
0·1	0	0·0052	Moribund or paralysed; unable to walk	Moribund or dead	All dead

When tested against recently hatched unfed adults of *Cimex lectularius*, the toxicity of 'Gammexane' acting purely as a contact insecticide was also found to be reduced by triolein. The bugs were placed in groups of 10 on filter papers (7 cm. diameter) to which had been applied various mixtures of an acetone solution of 'Gammexane', kerosene and triolein, followed by air-drying for 48 hours before testing. The results, for which no obvious explanation suggests itself, are shown in the accompanying table.

It is of interest to note that when fed to a rabbit, 'Gammexane' mixed with olive oil does not lose its toxicity for bedbugs afterwards fed on the animal. Further, we have been unable to show that *i*-inositol exerts any inhibitory action against 'Gammexane' in tests with mosquito larvæ. The results of our experiments with mosquito larvæ serve to amplify the observations of Buxton[1] and Upholt[2] concerning the loss of toxicity of D.D.T. when used as a larvicide. If, as suggested by Buxton, D.D.T. dissolves from oil into water in concentration sufficient to be larvicidal, or as Arnold *et al.*[5] conclude, is precipitated out on evaporation of the oil, then the eventual adsorption on the organic constituents of the bottom mud and the intervening ingestion by larvæ of the toxic agent (in aqueous solution or in a state of fine suspension) from subsurface levels would appear to be a factor of some import in the application of larvicides for control of breeding. The greater solubility of 'Gammexane' compared to D.D.T. therefore offers possibilities for more efficient control, particularly of those larvæ which do not rise to the surface (for example, species of the genus *Tæniorhynchus*).

We are indebted to Dr. Walmsley, of African Explosives and Chemical Industries Ltd., for supplies of 'Gammexane', and to Miss U. B. Arvidson for technical assistance.

Urceolarian Epizoites of Flatworms

PERITRICHS (Urceolaridæ) living on the surface of flatworms seem to afford suitable material for a study of the population dynamics of the epizoic habit. The host is widespread, occurs in large numbers, and the smooth surface enables rapid estimation of the numbers of the epizoite. A technique has been developed whereby some twenty flatworms can be dealt with in an hour.

Up to date, two species of Urceolaridæ, *Urceolaria mitra* v. Sieb. and *Trichodina steinii* Clap. et Lach., have been recorded from five species of flatworm. There is also a considerable body of descriptive work on these two ciliates; but the ecology seems to have been neglected. The existence of a pond with a large flatworm population in the grounds of the Memorial Buildings, University College, Bangor, has afforded an opportunity of studying the seasonal population changes in *U. mitra*, and some interesting results are emerging. Two species of flatworm abound here, *Polycelis nigra* and *Dugesia lugubris*. Early work suggesting that the epizoite was confined to the former species was confirmed by examining four samples of worms from different parts of the pond. Of fifty-three *P. nigra* taken, all carried the ciliate, whereas the twenty-four *D. lugubris* were negative. Host specificity seemed absolute under natural conditions. No similar record has been found, although Peshkowsky[1] noted that both peritrichs were more abundant on *P. nigra* than on *Dugesia torva* or *D. lugubris*. So far, *T. steinii* has not been found in this pond, although more than five hundred flatworms have been examined.

The preference for *P. nigra* has been tested experimentally by exposing both species of worm simultaneously to *Urceolaria* in watch-glasses. Successful attachments were noted after two days—under experimental conditions *Urceolaria* rarely lived longer, unattached. In ten tests an average of four out of ten (limits, 1–7) *Urceolaria* became attached to *P. nigra*. They did not attach to *D. lugubris*, confirming the field preference. In further experiments *D. lugubris* alone was exposed, and in three out of ten tests attachment occurred, the numbers being 2, 1 and 3. In the last case the peritrichs lived at least eleven days. Thus under certain conditions specificity is not absolute, recalling Fulton's work[2] on the transference of *T. pediculus* from *Hydra* to the gills of Amphibia. Results suggest that the basis of field specificity may be the amount of pigment and its distribution—it does not seem to be ecological.

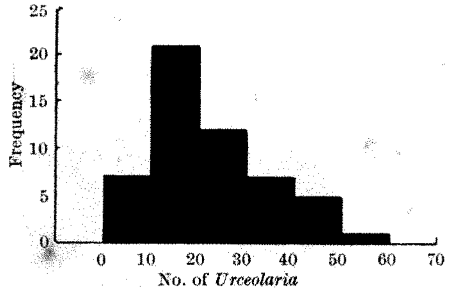

Fig. 1. URCEOLARIAN POPULATION OF *Polycelis nigra*

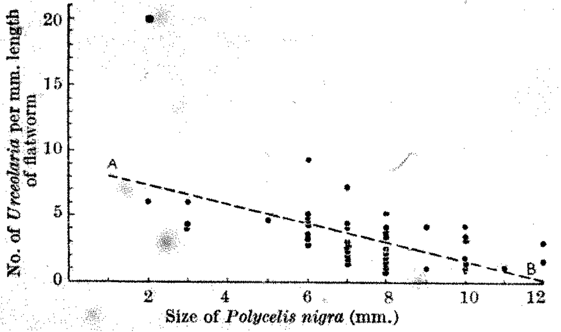

Fig. 2. NO. OF *Urceolaria* PER MM. LENGTH ON *Polycelis nigra*; *AB* IS THE REGRESSION LINE

Paucity of British records of this association[3] suggests that it is infrequent, but examination of flatworms from three other habitats in the Bangor district all yielded Urceolarians. *Polycelis cornuata* carried both species and is a new host record. Not only is the incidence of the epizoite high, but also individual flatworms may carry large populations. Fig. 1 summarizes the data for the College pond; the average number was 22 with limits of 6–55. Arrangement of the data in the form of a trend relating the Urceolarian population to flatworm size shows that the larger specimens do not carry a larger epizoic fauna. It follows (Fig. 2) that the larger flatworms carry a smaller population per unit area. The negative correlation between worm-size and the ciliate population is statistically significant. No explanation of this result, confirmed by later work, is available yet.

It is proposed to study the basis of host specificity, the ecological links between epizoite and host and the factors controlling the size and fluctuations of the peritrich population.

I am indebted to Miss M. Henderson for assistance in the field work and the preparation of this note.

A Fluorescent Reaction of Tryptophane

IN studying the colour reactions of tryptophane, described by J. Tillmans and A. Alt[1], an intense yellow fluorescence under ultra-violet light was observed.

This reaction has been somewhat improved by me for the purpose of fluorescent analysis. It is carried out by adding to 0·5–2 c.c. of the solution of tryptophane in a test-tube a few drops of a dilute solution of formaldehyde (about 4 per cent); the mixture is then shaken, and concentrated sulphuric acid cautiously poured to the bottom. At the contact of the liquid layers a yellow-brown ring appears, which shows intense yellow fluorescence under ultra-violet light. This fluorescence is readily observable with the naked eye in solutions containing 5 γ per c.c., that is, in a dilution of 1 : 200,000. After shaking, the whole solution shows yellow fluorescence. Solutions containing only the tryptophane fluoresce a bright blue under ultra-violet light.

I have not yet succeeded in isolating the fluorescent colouring matter. It is possibly a 4-carbolin derivative, as a carbolin ring is readily formed by the action of aldehydes upon tryptophane[2,3].

The colouring is permanent. The intensity of fluorescence remains in a stoppered test-tube unchanged for several months.

ACTIVATION OF COPPER BY OXIDATION AND REDUCTION

By F. C. ALDRED and Dr. F. HAPPEY
Courtaulds, Ltd.

PRELIMINARY X-ray observations on the crystalline changes produced in the metallic and oxide films of copper during the activation process appear to supplement the results of Garner and Stone[1]. The accompanying X-ray diagrams were obtained from narrow slivers of rolled copper sheet 0·0025 in. thick, using copper K_α radiation filtered through nickel foil to remove the β component. A flat quadrant plate spectrometer was used for the comparative X-ray measurements.

In each photograph, quadrants 1 and 3 show the reflexions from the (111) and (020) planes of the bright copper sheet together with faint reflexions from oxide inclusions. These photographs are typical of a metallic structure which is made up of finely divided crystals with preferred axes of orientation due to the rolling process. This specimen was to all intents and purposes inactive as a catalyst.

Quadrants 2 and 4 of Fig. 1 show the X-ray diagram of a sliver of copper strip after oxidation in air at about 850° C. for approximately five minutes. From this X-ray photograph two points are clear: (1) The remaining copper phase has recrystallized into a macro-crystalline form, with destruction of the preferred orientation. (2) The oxide phase is in the form of a finely divided powder which appears to be a mixture of cupric and cuprous oxides.

Quadrants 2 and 4 of Fig. 2 show an X-ray diagram of an oxidized sample of foil after reduction in hydrogen at 250° C. over a period of about one hour and at such a rate that no destruction of the catalytic action of the material was caused by local increases in temperature. The resulting metallic copper can be seen in two forms: one finely divided, from which the reflexions formed a continuous ring on the X-ray diagrams (quadrants 2 and 4, Fig. 2), and the other giving a series of reflexions from individual macroscopic crystals.

During this reduction process, control of temperature is vitally important; in general, it can be said that as the temperature is increased above the optimum of about 250° C., the catalytic action of the resulting copper decreases.

In our opinion, the probable mechanism of activation is as follows.

The outer surface of the copper sheet is oxidized to Cu_2O, which increases the volume occupied by the four copper atoms of the cubic unit cell[2] of the metallic state from $(3{\cdot}608\ \text{A.})^3 = 46{\cdot}93\ \text{A.}^3$ to $(4{\cdot}25\ \text{A.})^3 = 76{\cdot}87\ \text{A.}^3$ in the cubic unit cell comprising two Cu_2O molecules[3], with consequent change in density from 8·93 gm./c.c. to 6·14 gm./c.c. To achieve this, an obvious break-up of the surface of the copper must occur, even though the finely divided crystals of the original sheet are sufficiently mobile to recrystallize into a macro-structure. The further oxidation to cupric oxide also causes an additional slight increase in volume, since the monoclinic cupric oxide unit cell[4] contains four CuO molecules in a volume of $4{\cdot}653 \times 3{\cdot}41 \times 5{\cdot}108 \sin 80° \ 31' = 79{\cdot}94\ \text{A.}^3$; this results in an increased density of 6·569 gm./c.c. This increase in volume on oxidation causes the films of oxide to buckle and crack with the production of small crystals, so that there is always a possibility of oxygen reaching the copper surface.

From a consideration of these results and those of Garner and Stone, we suggest that the following theory might explain, in part, the difference between the reduction of copper by hydrogen and by carbon monoxide at low temperatures, and also account for some, if not all, of the specific effect of hydrogen in producing an activated copper.

The heats of reduction of copper oxide by hydrogen and carbon monoxide are approximately equal, but the thermal conductivity of hydrogen is about seven times that of carbon monoxide. In the case of reduction by hydrogen, the heat generated is rapidly removed from the reaction zone because of the high conductivity of the hydrogen, and the high temperature at these points is not maintained for a sufficient period of time to allow extensive migration of the copper atoms to form large crystals. A porous matrix is therefore produced. Further, as the porosity of the copper is increased during the course of the reaction, the internal surface area increases, thus augmenting the cooling effect and encouraging the formation of a spongy structure.

In the case of reduction by carbon monoxide, only when the copper oxide is in a finely divided state and separated by spacings sufficiently large to facilitate the entry of carbon monoxide into the intercrystalline structure can reduction be carried out at a rate similar to that obtaining with hydrogen. This reduction is most probably accompanied by a recrystallization of the copper into a compact metallic structure, the cooling effect being much less owing to the poorer conductivity of carbon monoxide. This consequent decrease in surface area is responsible for the lower catalytic activity of the resulting

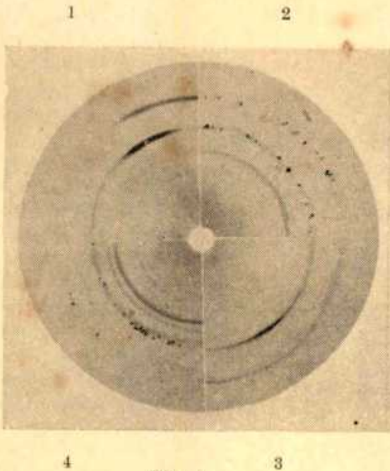

Fig. 1

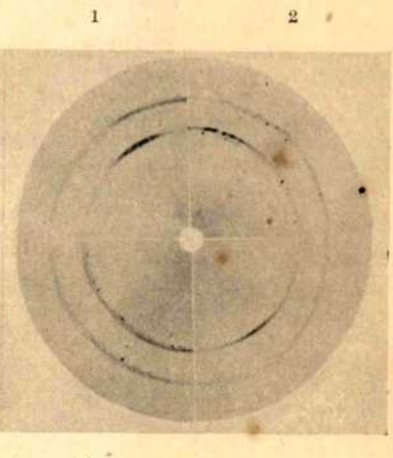

Fig. 2

Fig. 1. X-RAY PHOTOGRAPHS OF QUADRANTS 1 AND 3 ORIGINAL BRIGHT COPPER SHEET; QUADRANTS 2 AND 4 OXIDIZED COPPER SHEET. COPPER K_α RADIATION, $D = 2$ CM.

Fig. 2. X-RAY PHOTOGRAPH OF QUADRANTS 1 AND 3, ORIGINAL BRIGHT COPPER SHEET; QUADRANTS 2 AND 4, HYDROGEN REDUCED COPPER SHEET AFTER OXIDATION. COPPER K_α RADIATION, $D = 2$ CM.

copper. Following a second oxidation, the reduction with carbon monoxide proceeds with difficulty as the intercrystalline spaces are smaller and the penetration of the carbon monoxide does not occur so readily.

Comparing the crystal size of the activated copper and that of the original rolled sheet, it can be seen that the essential difference between an active and an ordinary copper is not primarily one of crystal size, but of porosity. Thus we suggest that hydrogen reduction under carefully controlled conditions produces an activated copper because the breakdown of oxide crystals occurs without extensive migration of the metallic atoms, and a spongy copper matrix is 'frozen' into position. When carbon monoxide is used, the heat generated is not conducted away from the zone of reaction so rapidly, and recrystallization occurs, with a consequent decrease in the intercrystalline spaces, and the formation of a less porous metal, which becomes increasingly difficult to penetrate with the CO molecule.

We wish to thank the directors of Messrs. Courtaulds, Ltd., for permission to publish this note.

EFFECT OF GAMMA- AND X-RAYS ON DILUTE AQUEOUS SOLUTIONS OF ACRYLONITRILE

By Dr. F. S. DAINTON
Dept. of Physical Chemistry, Cambridge

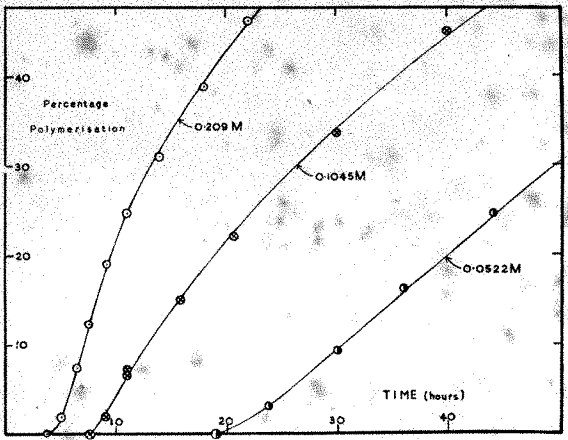
THE immediate effect of the absorption of high-energy radiation (α-, β-, γ- and X-rays, fast protons, deuterons, etc.) by water is the ejection of electrons from the water molecules lying along the tracks of the rays. There has been much discussion concerning the mechanism of the chemical changes which occur in water or dilute aqueous solution as a result of this 'primary radiochemical act'. Many of the investigations[1] have been concerned primarily with measurement of the ion pair yield (M/N is number of product molecules formed or reactant molecules decomposed per ion pair), and for such purposes it was sufficient to regard the radiation as producing 'activated water'[2], an unspecified intermediate capable of bringing about the observed changes and formed in amounts proportional to the dose. Recent reconsideration of the types of chemical reactions undergone by the solutes has led to the view, proposed by Weiss and now widely held[3], that the activated water consists of a hydrogen atom and hydroxyl radical, formed possibly by direct dissociation of water, or by electron capture and ion breakdown processes such as

$$\begin{gathered} H_2O^+ + e \rightarrow H^\cdot + -OH, \\ H_2O^+ \rightarrow H_{aq}^+ + -OH, \\ H_{aq}^+ + e \rightarrow H^\cdot. \end{gathered}$$

In order to test this view, it was decided to investigate whether types of reaction known to be brought about by neutral entities such as $H^\cdot$ or $-OH$, but unaffected by high concentrations of hydrogen or hydroxyl ions, could be induced in dilute aqueous solution by irradiation with X- or γ-rays. To obtain reaction times of reasonable length with the X- and γ-ray sources commonly available, it is necessary to use a reaction for which it is likely that $M/N \gg 1$. It was felt that a polymerization chain-reaction would be particularly suitable. The monomer selected was acrylonitrile, the polymerization of which in aqueous solution can be initiated by hydroxyl radicals generated either by the reaction[4],

$$Fe_{aq}^{++} + H_2O_{2_{aq}} \rightarrow Fe_{aq}^{+++} + OH_{aq}^- + -OH,$$

or by the photolysis by light of wave-lengths greater than 3000 A. of $H_2O_{2_{aq}}$[5]. Moreover, work on the polymerization sensitized by hydrogen atoms of vinyl compounds in the gas phase[6] suggests that hydrogen atoms in water should also initiate the polymerization of this type of solute. On the other hand, we have found air-free aqueous solutions of acrylonitrile containing high concentrations of hydrogen and hydroxyl ions ($N/2$ sodium hydroxide or sulphuric acid) to be stable for indefinite periods. The experiments outlined below, and of which full details will be published elsewhere, were therefore carried out. The results provide additional evidence for the formation of hydrogen atoms and hydroxyl radicals in water irradiated by X- and γ-rays.



POLYMERIZATION OF ACRYLONITRILE IN DILUTE AQUEOUS SOLUTION AT 20° C. SOURCE: 600 MC. RADIUM IN PLATINUM CYLINDER. RADIATION: γ-RAYS, 0·2406–1·761 MEV. ~ $3 \cdot 6 \times 10^9$ QUANTA CM.^{2} SEC.$^{-1}$ AT 1 CM.

The glass reaction cell, of 20-ml. capacity and with a central cavity into which the radiation source could be closely fitted, was filled with the solution of the monomer in de-aerated water and precautions taken to exclude air. The source (600 mC. radium in a platinum cylinder) was introduced for allotted time intervals, and the extent to which polymerization had occurred was determined by separating the precipitated polymer (either by filtering or centrifuging), washing with methanol and drying at 70° C. to constant weight. Results obtained in this way are given in the table, and some of the percentage polymerization-time curves shown in the accompanying figure. In each run there was an interval before the development of turbidity, which was the first sign of the polymerization. The reaction was also induced by X-rays from an industrial radiography unit operating at 10 mA. and 200 kV., but quantitative measurements have not yet been made.

The data given in the table indicate that, with a γ-ray source, the reaction is of second order with respect to the monomer concentration, and independent of source strength. The ion pair yield (M/N) is at least 10^4 for the 600 mC. source at the highest concentration used, and varies inversely with source

Source strength	Approximate dose-rate*	Monomer concentration	Percentage polym. per hour at steady rate	Second order rate constant × 10^4	Turbidity time
600 mc.	40 r. min.$^{-1}$	0·209 *M.*	4·05	5·4 l.mole^{-1} sec.$^{-1}$	3·7 hr.
„	„	0·1045 *M.*	1·95	5·2 „ „	8± 0·4 „
„	„	0·0522 *M.*	1·07	5·7 „ „	19± 1 „
„	„	0·178 *M.*	3·49	5·45 „ „	3·4 „
1200 mc.	80 „	„	3·7	5·8 „ „	1·95 „

* Calculated as 78 r. min.$^{-1}$ at the surface of the source, a value which agrees with ionization measurements at 3·75 cm. from this source.

strength. These results may be accounted for by assuming that the chemically significant primary act in these experiments is†

$$H_2O \overset{\gamma}{\rightsquigarrow} H^{\cdot} + -OH, \qquad (1)$$

and that the polymerization chain is initiated by the products of this reaction, that is,

$$H^{\cdot} \text{ or } -OH + m_1 \rightarrow m^*_1, \qquad (2)$$

propagated by

$$m^*_j + m_1 \rightarrow m^*_{j+1}, \qquad (3)$$

and terminated by interaction with a hydrogen atom or hydroxyl radical

$$m^*_j + H^{\cdot} \text{ or } -OH \rightarrow m_j. \qquad (4)$$

Chain transfer has been disregarded because it would not affect the rate of monomer consumption, and conceivable chain-transfer reactions with water are appreciably endothermic. Chain termination by interaction of growing chains in pairs is eliminated since it leads to a dependence of the rate on source strength and monomer concentration which has not been observed; it would be first order if all the hydrogen atoms and hydroxyl radicals are removed by reaction and none by re-combination, but 1·5th order if reaction 2 is slow compared with recombination of hydrogen and hydroxyl. Confirmation or otherwise of reaction 4 as the chain-ending process would have been possible from measurements of the molecular-weight distributions at different source strengths, since on the above scheme the chain length ($= 2\ k_2\ k_3\ m_1{}^2/k_4\ R$, where R is the rate of production of radicals in reaction 1) should decrease with increase of source strength. Unfortunately, the samples essential for these determinations did not survive transit, but it is hoped to test this point in the future.

It is of interest that Baxendale, Evans and collaborators[7], in a recent study of the polymerization of methyl methacrylate in aqueous solutions initiated by hydroxyl radicals produced by the Fe^{++}/H_2O_2 reaction, find the predominant mode of chain termination to be in pairs. However, at high initiator concentrations, deviations from their kinetics are found ". . . due to termination by the OH radical . . ." (ref. 7, p. 680). If, as seems likely, a similar effect would be observed in the polymerization of acrylonitrile solutions when the Fe^{++}/H_2O_2 catalyst is used, then it must be presumed that the hydrogen atoms and hydroxyl radicals formed in the solution irradiated by γ-rays are unevenly distributed throughout the system. Such high local concentrations would be expected along the tracks of the fast secondary electrons released by the radiation, and it is of interest that, in the case of X-rays, Lea (*op. cit.*, ref. 3, p. 52) has advanced other evidence for this type of radical localization.

The cause of the induction period (that is, turbidity time) is not yet known. Bacon and Evans *et al.*[8] have demonstrated that traces of oxygen lengthen the induction period in reduction activated polymerization of aqueous acrylonitrile solutions; but in our experiments great care was taken to exclude oxygen. The observed dependence of the turbidity time on monomer concentration and source strength (column 6 of the table) can readily be accounted for on the kinetic scheme proposed, provided it is assumed that the (unknown) inhibitor is destroyed by reaction with either or both of the products of reaction 1, as well as by reaction with growing polymer chains.

I am greatly indebted to Dr. N. Miller for frequent discussions and for his help, without which these experiments could not have been brought to the present stage, in the limited time available; to the National Research Council of Canada and the Ministry of Supply for hospitality and facilities; and to Dr. D. E. Lea for discussion.

HYPER- AND AVITAMINOSIS IN MICRO-ORGANISMS

By Dr. M. N. MEISSEL

Institute of Microbiology, Academy of Sciences of the U.S.S.R., Moscow

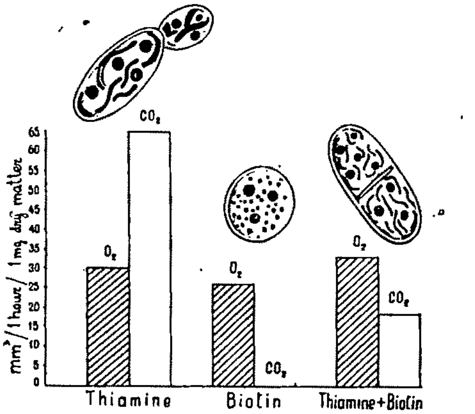
THE influence of vitamins on micro-organisms is usually estimated according to their accelerating effect upon the growth-rate of micro-organisms. However, cases are known in which some morphogenetic or physiological effects are clearly observed without any visible influence upon the growth-rate. On the other hand, increased growth-rate of the cells cannot always be considered as being due to the presence in the culture of a complete set of the vitamins necessary for normal development. Our morphological and physiological investigations of micro-organisms have shown them to be highly susceptible to changes in vitamin supply.

It has been found that the absence of certain vitamins necessary for normal development of the micro-organism may, nevertheless, result in a great increase of the yield. But after some days, because of insufficiency of their protoplast, the cells begin to die and the culture may be completely lost. The data presented below illustrate this point.

The yeast-like fungus *Endomyces magnusii* needs for normal development on Reader's synthetic medium (in which vitamin-free casein hydrolysate is used as a source of nitrogen) chiefly two vitamins namely, thiamine and biotin. Thiamine may be replaced by 4-methyl-5-oxyethyl-thiazole (vitamin thiazole). Each of these vitamins activated to some extent multiplication of this organism. When applied together, they lead to a great increase of yield[1]. If only thiamine or vitamin thiazole was added to the synthetic medium, the cells of *Endomyces magnusii* accumulate glycogen, volutin and this vitamin also. Cytological observation shows that the nuclei of this organism are enlarged and the chondriosomes are much hypertrophied. Since the features just mentioned are characteristic for the development of this fungus in relatively anaerobic conditions, we have termed this type of cell as the anaerobic or fermentating one[2]. Physiological tests showed that the culture grown in the presence of thiamine possessed the power of fermentation energy five to eight times as large as that in the culture grown in the absence of thiamine. It is of interest to note that the re-organisation in question is taking place in the presence of thiamine even in the aerobic condition, when the fungus is cultivated on the surface of the solid medium[3]. Accumulation of thiamine under these conditions amounts to 120–150 mgm. per gm. of dry material. Such a condition of *Endomyces magnusii* cells may be considered as a thiamine-hypervitaminosis, since the morphological and physiological features of the culture are very different when it is grown on the medium containing the complete set of vitamins. They will be described later, in connexion with a consideration of the combined influence of thiamine and biotin.

If biotin only is added to Reader's synthetic medium, the culture grows for two or three days and then dies off. The cells are spherical. Their protoplasm is heavily vacuolated and completely lacks glycogen and volutine. The chondriosomes are small and dust-like. Such a culture is not capable of fermentation to any noticeable extent and practically lacks thiamine. From the third day onwards, very intensive plasmolysis, coagulation, and necrobiosis of the protoplast take place. The great majority of the cells die off, and then serve as a substrate for single developing cells. There is every reason to interpret this picture as a thiamine-avitaminosis exaggerated by one-sided activation of multiplication, induced under the influence of biotin. Finally, if the medium contains both thiamine and biotin, the whole mass of the culture is extraordinarily increased. All the cells are alive, and elongated in shape. Their protoplasm is well developed, with a large number of fat inclusions. Only small amounts of glycogen and volutin are present. Thin rod-like or thread-like chondriosomes are scattered throughout the cytoplasm. These cultures are characterized by very high consumption of oxygen and weak, although quite measurable, power of fermentation. Such a type almost coincides with the normal culture, grown on the natural solid medium, for example, on the wort-agar medium, and may be designated as a normal aerobic or respiratory one. In the accompanying diagram data are given on the intensity of fermentation and oxygen consumption in cultures grown under conditions of different vitamin supply.

Pathological avitaminous conditions are also readily produced in representatives of the genus *Saccharomyces* when the normal vitamin supply necessary for development breaks down. In this case the depression is especially marked in the absence of pantothenic acid and thiamine.



CYTOLOGICAL APPEARANCE, RATE OF CARBON DIOXIDE PRODUCTION AND OXYGEN UPTAKE BY THE CELLS OF *Endomyces magnusii* GROWN ON SYNTHETIC MEDIA CONTAINING VARIOUS VITAMINS

The conclusion to be drawn from the data presented above is that the vitamin complex necessary for the normal development of micro-organisms is in many cases more than enough for quite intensive growth of the cells. It may well be that intensively growing culture lacking any one factor even of minor importance will show some kind of biological insufficiency. Therefore, there is no reason to regard the intensive growth-rate of the culture as a reliable means for determining the growth factors necessary for normal development of micro-organisms. An incomplete set of the growth factors breaks up their interregulating influence and may lead to extreme one-sided activation of some cell functions; the latter, in turn, gives rise to development of hyper- and avitaminosis.

CARCINOGENIC ACTIVITY OF PREPARATIONS RICH IN CHOLESTEROL

By DR. I. HIEGER

Chester Beatty Research Institute, Royal Cancer Hospital (Free), London

AN earlier report from this Institute[1] recorded that carcinogens had been detected in fractions from human tissues (liver, lung, kidney and muscle) obtained from cancerous and non-cancerous subjects. The activity was concentrated in the cholesterol-rich (*c.* 85 per cent) fraction of the unsaponifiable part of the tissue, and it was suggested (*loc. cit.*, p. 666) that cholesterol itself may not be inert in the carcinogenic process. The further data now available and tabulated below (Table 1) are not incompatible with the hypothesis that cholesterol itself may be carcinogenic, although the alternative view that preparations rich in cholesterol may contain small quantities of an unknown but potent carcinogen cannot yet be excluded; very pure cholesterol prepared chromatographically by Dr. Shoppee is now under test in this Institute.

TABLE 1

*C*57 strain mice	Initial No. of mice	No. of sarcomas (at site of injection)
Materials tested		
Commercial cholesterol	43	5
9 cholesterol-like compounds (cholesterylene, 7-dehydrocholesterol, etc.)	100	0
Cholesterol-rich fractions from mammalian (cattle) liver	30	0
Commercial cholesterol + certain animal and vegetable oils	60	0
,, ,, + cod liver oil	10	3
,, ,, + unsaponifiable fractions of human liver	20	0
,, ,, + sesame oil	10	1
,, ,, refluxed with KOH and alcohol	20	0
Unsaponifiable fraction of human bile and gall bladders (cholesterol content *c.* 90%)	40	1
,, ,, ,, cream (cow's milk) (cholesterol content *c.* 90%)	10	1
,, ,, ,, rat tumour tissue	15	0
Lard alone	10	0
Unsaponifiable fractions of human tissue (cholesterol content 90% and downwards)	227	3
	595	14
Mixed stock mice		
Human liver, unsaponifiable fractions (cholesterol content 90% and downwards)	260	3
Unsaponifiable fraction of gall stones	10	0
M.R.C. strain mice		
Commercial cholesterol	21	2

The technique of testing was described in detail in the paper referred to above; in brief, the essential features were: (1) The material for test were dissolved in lard at 15 per cent concentration (except for the sesame oil experiment). (2) Injection in mice were made subcutaneously in the flank (0·1–0·4 c.c.) at fortnightly intervals; injections were suspended as long as a reservoir of material could be detected by touch. If groups of mice died early in the experiment, they were replaced so as to ensure that a satisfactory number of animals survived long enough in all tests.

The small number of solvent controls (10 mice) need cause no concern, for all the negative results with *C*57 mice (namely, 595 − 14 = 581) constitute the controls on the solvent (lard). More than 300 controls on lard have been carried out on mixed stock mice without producing a single sarcoma[1,2]. One must mention, however, that a closely allied species, the rat, behaves differently, for evidence is accumulating that it is liable to sarcoma production by the subcutaneous injection of a variety of fatty substances of animal and vegetable origin.

The latent periods for the different groups of tumours, that is, those produced by commercial cholesterol in lard only and those produced by the other preparations, show much overlap (Table 2).

TABLE 2. LATENT PERIOD OF TUMOURS IN TABLE 1 (MONTHS)

Commercial cholesterol in lard	U.F.* of bile + lard	Commercial cholesterol + sesame oil	Commercial cholesterol + cod liver oil + lard	U.F. of human tissue fractions + lard	U.F. of cream + lard
11	29	14	20	18	13
23			23	19	
13			25	19	
20				16	
22				12	
22				16	
23					

* U.F. = unsaponifiable fraction.

The total production of sarcomas in mice at the site of injection by substances of biological origin is given in Table 3, which represents the chief results of experiments in progress in this Institute up to the time of writing[1,2,3].

TABLE 3

	Material	Total sarcomas
1.	Unsaponifiable fraction of cow's milk (experiments of Prof. E. L. Kennaway)	1
2.	Unsaponifiable fraction of cream (cow's milk)	1
3.	Commercial cholesterol	11
4.	Unsaponifiable fraction of human tissues (liver, lung, kidney, muscle) and bile from cancerous and non-cancerous subjects	31
	Ether extract (that is, saponifiable) of human cancerous liver	2
6	Ether extract (that is, saponifiable) of mouse mammary tissue	1

The foregoing data now suggest three possibilities:

(1) That cholesterol is, in fact, a slow carcinogen, particularly in the presence of other facilitating lipids, and in the absence of inhibiting factors.

(2) That commercial cholesterol (cholesterol content high but uncertain, of the order of 98 per cent perhaps) contains a small amount of an unknown but potent carcinogen; and that cholesterol-rich fractions from human tissues (liver, lung, kidney and muscle), from cow cream, from cattle brain and spinal cord, and from human bile all contain, in addition to cholesterol, the unknown carcinogen.

(3) The operation of unknown factors (for example, important variations of susceptibility of the experimental mice).

This work was supported by grants-in-aid from the British Empire Cancer Campaign, the International Cancer Research Fund, the Anna Fuller Fund and the Jane Coffin Childs Memorial Fund for Medical Research.

Note added in proof. At the time of writing there are still a few surviving mice in the experiments described in the tables. Thus the total of tumours shown is a minimum figure and may have to be slightly raised when all the mice are dead.

FORTHCOMING EVENTS

Wednesday, August 27—Wednesday, September 3

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE (at Dundee).—109th Annual Meeting.

Wednesday, August 27

In the Caird Hall, City Square, Dundee, at 8.30 p.m.—Sir Henry Dale, O.M., F.R.S.: "Science in War and Peace" (Presidential Address).

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT PHYSICISTS (2) in the Radiotherapy Service, and an INSTRUMENT MAKER—The Secretary, South Wales and Monmouthshire Joint Cancer Committee, County Hall, Newport, Mon. (August 30).

PRINCIPAL OF THE IPSWICH SCHOOL OF TECHNOLOGY—The Chief Education Officer, 17 Tower Street, Ipswich (August 30).

LECTURER IN PHYSICS, and a LECTURER IN CHEMISTRY—The Clerk to the Governors, South-East Essex Technical College, Longbridge Road, Dagenham (August 30).

RESPONSIBLE LECTURER IN PHYSIOLOGY (Senior Assistant)—The Principal, Chelsea Polytechnic, Manresa Road, London, S.W.3 (August 30).

UNIVERSITY LECTURER IN MATHEMATICS, with special qualifications in Statistics—The Secretary, Appointments Committee of the Faculty of Mathematics, Trinity College, Cambridge (August 30).

ASSISTANT MASTERS in H.M. Dockyard Schools (one each at Portsmouth and Chatham)—The Director, Education Department, Admiralty, London, S.W.1 (August 30).

LIBRARIAN, and an ASSISTANT LIBRARIAN, at the Coventry Technical College—The Director of Education, Council House, Coventry (August 30).

SENIOR ASSISTANT IN ELECTRICAL ENGINEERING in the Bournemouth Municipal College—The Education Officer, Town Hall, Bournemouth (August 30).

Lecturer in Mechanical Engineering—The Registrar, Merchant Venturers' Technical College, Unity Street, Bristol 1 (August 30).

Lecturer in Mechanical Engineering—The Principal, Dudley and Staffordshire Technical College, Dudley (August 30).

Senior Assistant in Civil Engineering, a Senior Assistant in Electrical Engineering, a Responsible Lecturer in Mechanical Engineering, and a Lecturer in Electrical Engineering—The Registrar, Nottingham and District Technical College, Shakespeare Street, Nottingham (August 30).

Assistant Bacteriologist and Lecturer in Bacteriology—The House Governor, King's College Hospital, Denmark Hill, London, S.E.5 (August 31).

Vice-Principal and Senior Lecturer in Agriculture, an Assistant Lecturer in Agriculture with special knowledge of Farm Machinery, an Assistant Lecturer in Agriculture with special knowledge of Dairying, and a Senior Instructress in Rural Domestic Economy—The Principal, Yorkshire Institute of Agriculture, Askham Bryan, York (September 1).

Head of the National Foundry College being established to provide for technical education and research in connexion with the Foundry Industry (Ferrous and Non-Ferrous)—The Clerk to the Board of Governors, National Foundry College, at the Wolverhampton and Staffordshire Technical College, Wulfruna Street, Wolverhampton (September 6).

Educational Psychologist—The Secretary for Education, County Buildings, Shrewsbury (September 6).

Teacher of Physics and Radio for day and evening classes—The Secretary, Norwood Technical Institute, Knights Hill, West Norwood, London, S.E.27 (September 6).

Lecturer for advanced teaching and the supervision of research in organic chemistry—Sir Ian Heilbron, F.R.S., Royal College of Science, Imperial College of Science and Technology, South Kensington, London, S.W.7 (September 12).

Assistant Lecturer in Pure Mathematics—The Registrar, The University, Manchester 13 (September 13).

Lecturer in Metallurgy—The Registrar, The University, Leeds 2 (September 15).

Lecturer in Physics—The Principal, Heriot-Watt College, Edinburgh (September 15).

Lecturer in Physiology—The Secretary and Bursar, Royal Veterinary College and Hospital, Royal College Street, London, N.W.1 (September 15).

Inspector under the Dangerous Drugs Acts—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 1958 (September 16).

Senior Principal Scientific Officer in the Radio Department of the Royal Aircraft Establishment, Farnborough, Hants, under the Ministry of Supply—The Secretary, Civil Service Commission, Scientific Adviser's Branch, 27 Grosvenor Square, London, W.1, quoting No. 1962 (September 18).

Tutorial Studentships in (*a*) Physics, and (*b*) Mechanical Engineering—The Secretary, King's College, Strand, London, W.C.2 (September 20).

Lecturer in Physics—The Principal, Royal Holloway College, Englefield Green, Surrey (September 20).

Singhanee Lecturer in Fuel Technology—The Registrar, University of Bombay, Bombay 1, India (September 29).

Geologists, and Senior Geologists, in the Geological Survey of Great Britain—The Secretary, Civil Service Commission, Scientific Adviser's Branch, 27 Grosvenor Square, London, W.1, quoting No. 1963 (September 30).

Assistant Conservators of Forests (2) for the Department of Agriculture and Forests, Sudan Government—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1, endorsed 'Forests' (October 1).

Geneticist (Senior Research Officer or Principal Research Officer), a Silviculturist (Senior Research Officer or Principal Research Officer), a Chemist (Research Officer or Senior Research Officer), and a Plant Pathologist (Research Officer or Senior Research Officer), at the new Wattle Research Institute attached to the Natal University College, Pietermaritzburg—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (October 30).

Artist-Secretary for Pathological Museum—The Dean's Office, St. Thomas's Hospital Medical School, London, S.E.1.

Head of the Mathematics Department—The Principal, Huddersfield Technical College, Huddersfield.

Fish Expert by the Iraqi Government Ministry of Economic Affairs—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.N.14573.

Lecturer in Physics at the Leeds College of Technology—The Director of Education, Education Department, Calverley Street, Leeds 1.

Lecturer in Biology, with special knowledge of Zoology—The Principal, West Ham Municipal College, Romford Road, Stratford, London, E.15.

Head of the Electrical Engineering Department—The Registrar, Portsmouth Municipal College, Portsmouth.

Senior Assistants in the Departments of Civil and Mechanical Engineering, Electrical Engineering, and Physics—The Secretary, Northampton Polytechnic, St. John Street, London, E.C.1.

Lecturer in the Department of Biochemistry—The Secretary, The University, Edinburgh.

Demonstrator in the Department of Pharmacy—The Secretary, Royal Technical College, Glasgow.

Laboratory Technician (Grade B) in the Physiology Department, and a Laboratory Technician (Grade C) in the Chemistry Department—The Warden and Secretary, Royal Free Hospital School of Medicine, 8 Hunter Street, London, W.C.1.

Graduates in Physics or Chemistry to conduct research into problems connected with the manufacture of pottery—The Director of Research, British Pottery Research Association, Queen's Road, Penkhull, Stoke-on-Trent.

Laboratory Technician (Grade B) in the Area Pathological Laboratory—The Medical Officer of Health, Municipal Buildings, Middlesbrough.

Lecturer or Assistant Lecturer in Zoology—The Registrar, University College, Exeter.

Graduate in Agriculture with organising ability and experience both of teaching and practical farming, as Headmaster of the Jamaica School of Agriculture—The Director of Recruitment, Colonial Service, 15 Victoria Street, London, S.W.1.

Senior Assistant in the Department of Mechanical and Automobile Engineering, Doncaster Technical College—The Chief Education Officer, Education Office, Wood Street, Doncaster.

Graduate with First- or Second-Class Honours or Higher Degree in Chemistry, and a Graduate with special qualifications in Engineering—The Principal, Mining and Technical Institute, Neath.

SWORDS INTO PLOUGHSHARES

THE British Association was holding its annual meeting in Dundee in 1939 when war was declared. Appropriately enough, the Association is now holding its first full-time post-war meeting in the same city. It was therefore a wise decision on the part of the Council of the Association to arrange that the general theme at the meeting should so far as possible be "Swords into Ploughshares". The contribution of science to human progress is mainly positive and constructive, no matter whether it be fundamental or specifically applied; most men of science would wish that it were completely so. But in warfare of this modern age men of science have their part to play, distasteful though it may prove to be. Yet scientific research carried out as part of the strategy of war almost invariably yields results which, despite the fact that they might be destructive in war-time application, present much useful material and data for the positive pursuits of peace-time. This is well brought out in the addresses of the presidents of the various sections of the Association, but nowhere more so than in Sir Henry Dale's general presidential address entitled "Science in War and Peace" (p. 280).

In facing realities we must agree that the world is not yet at peace, neither is it free from the threat of further conflagration, perhaps even on a world-wide scale. It follows that though every effort towards world peace must be made, it would be foolish during present troublesome times to fall into a state of lethargy and unpreparedness. So some scientific research, especially that dealing with certain aspects of atomic energy, must even now, and perhaps for some time to come, be carried on under the ban of official secrecy. Feeling is high these days, and concern is often expressed that military secrecy might take the place of former industrial interests in slowing up the free flow of ideas which are essential to the smooth progress of scientific endeavour. But at present men of science must face the fact that some secrecy is inevitable, and this makes it all the more imperative, therefore, that they themselves should strive to bring before each other and above all before the general non-scientific public the many beneficent aspects of science. It is doubtful if even men of science themselves fully appreciate the general trend of public opinion concerning science, especially since the advent of the atom bomb. Public opinion, even in high places, if sometimes not well informed, is nevertheless expressed and sometimes acted upon. Some fear that science might become more and more a tool for enforcing one or another political credo and for use in diplomatic intrigue. It is for men of science to prevent this so far as they possibly can. Science must play an important part in international relations; but, at any rate during times of peace, let that be a constructive one. We already have it in the United Nations Food and Agriculture Organisation and it is developing in the United Nations Educational, Scientific and Cultural Organisation.

Yet with all this, opinion is still divided, and even among some scholars and students there are powerful 'anti-science' groups; men who should know better have been heard to express alarm at the march of science and demand the fettering of science and scientific workers. This must not be ignored, and it is therefore best countered by men of science themselves telling the world (so far as they are allowed) of their work, stressing especially the value of their discoveries to man and the profound importance of the impact of science on a modern human society.

Sir Henry Dale, in his presidential address, reiterated the aims of the Association in providing a forum for discussing the interests of science, and its proper place in the life of the community, of the nation and of the world. The word 'proper' is more significant to-day than it has ever been, for there is still much misunderstanding among non-scientific people, even up to the political level, about things scientific. This must be rectified, and it is mainly through such agencies as the British Association and by means of well-documented and written general scientific publications that this can be done.

As Sir Henry said, the concern of science with war was abnormal. Critics tend to forget the conditions under which men of science, like all other members of this and other nations, were working during the War. Most men of science then had a very definite and immediate aim; and all other things were made subservient to that. Working on those projects which aimed at destruction, they were well aware of what they were doing. Sometimes it must have demanded greater courage to carry on research in such circumstances than to abandon it on the grounds of conscience. Those same men of science in days of peace will be able to present their findings to humanity for the good of all; but that depends on national and international goodwill and above all on a true estimate and appreciation of science by the non-scientist. War-time discoveries may be applied, or will certainly lead, to other discoveries which will be for the good of man, finding himself as he does in social conditions becoming more and more affected by scientific achievement.

A week of meetings of the British Association is naturally more than an exposition of recent scientific achievement, though, even if it were narrowed down to this, since such achievement has now to be transferred from war-time use to peace-time applications, there is much work ahead—enough to change the entire pattern of social life, as the examples chosen by Sir Henry Dale serve to show. All listeners to, or readers of, this erudite summary of achievement will be grateful to Sir Henry for a choice wisely made; for no one but the most biased can, after digesting such fare, ignore the inestimable benefits that even war-time science must ultimately bestow on mankind, given the necessary atmosphere of peace and goodwill.

But Sir Henry also issues very pertinent and timely warnings to research workers themselves. For example, the distinction between war-time scientific research (the concentration of nearly all one's thoughts and efforts on practical problems the rapid solution of which was the sole objective) and peace-time research which demands taking a long-range view with the first care of extending fundamental knowledge unconstrained by aim at any practical objective, must be taken to heart by all scientific research workers, especially those of the younger generation who have had their first experience of research work in war-time laboratories.

Older research workers, also, should take to heart Sir Henry's plea that they should not be too ready to assume that their best service to science still lies in planning and organising, or in bringing scientific affairs to bear upon policy. Though in a world of planning men of science must have their say, and in international deliberations, both political and economic, the voice of science must be heard; in other words, though, as *Nature* has frequently demanded, men of science should be consulted and if desirable put into control where matters scientific are concerned, yet a sense of proportion must be brought to bear on this peace-time problem of transition so that it may be realized that the main work of the majority of our men and women of science must be carried out in the laboratories of fundamental research. The main aim must be the advancement of pure knowledge, the search for and exposition of the truth so far as scientific method can elucidate it. The material betterment of man's lot will, in the main, follow from this; in any event it is an ancillary aspect of a very noble calling.

AN ENCYCLOPÆDIA OF HUMAN GENETICS

Human Genetics

By Prof. Reginald Ruggles Gates. Vol. 1. Pp. xvi + 742. Vol. 2. Pp. vi + 743–1,518. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1946.) 2 vols., £3 15*s.* net.

THE rôle of the gene in the etiology of human defect and derangement is now widely recognized. In the medical curriculum a place for a course of instruction in genetics has been found. The dramatic discovery of the genetic nature of congenital hæmolytic disease has aroused among practitioners of medicine a keen desire to know more about this science, and they are asking for books which will give them the information and the guidance which they seek.

There are elementary text-books of high quality which adequately display and sufficiently illustrate genetic principles. There are monographs which deal with a particular organ, system or clinical entity and include references to most, if not all, instances of relevant genetic abnormality or abnormalities. Twenty-four years ago there appeared the very ambitious treatise of Baur–Fischer–Lenz, which attempted to include between the same covers all instances of genetic defect and derangement affecting each and every system of the human subject; and in 1929 what may be regarded as the forerunner of the book now under review, "Heredity and Man" by Prof. Ruggles Gates, dealing with the whole subject of the special genetics of man. These two did much to attract an interest in genetical science on the part of the anthropologist and the physician.

But developments in medical science and the more recent work on human genetics, together with the exceedingly rapid progress in genetical science generally, have outmoded all books written a decade or more ago. Teachers of genetics, among many others, have felt the need for an authoritative modern encyclopædic book of reference which would cover the whole field and which would lighten the burden of combing the vast and scattered literature for their illustrations and for the information on which they must base the advice for which they are so commonly approached.

Prof. Ruggles Gates has valiantly attempted to satisfy this need. The result of his long-sustained industry is a book which must attract the respect of all who are in a position to recognize the immensity and the difficulty of the task that he undertook. It is indeed a remarkable, a Herculean, performance. Its magnitude and comprehensiveness can perhaps best be measured by the size of the index, which occupies no less than 90 pages, and by the number of the references, some 5,500, to key papers and books.

As a book of reference these volumes must prove to be of the greatest usefulness. As a collector of pedigrees, Prof. Ruggles Gates must surely be unsurpassed, and to him much gratitude will be attracted through this service which he has rendered during the years of his retirement. But this is meant to be more than a book of reference. It is also a vehicle for the author's interpretation of recorded fact, for his views concerning the nature and cause of genetic phenomena. It is offered therefore as a text-book, and it is as such that its value must be assessed.

Prof. Ruggles Gates is a professional botanist and cytologist of high repute and an anthropologist of standing. He has made notable contributions to the advancement of these sciences. He is among the more prominent of eugenists. But his knowledge of human pathology and of clinical medicine is sufficiently limited to permit him to discuss their contents with an apparent ease which is not displayed by anyone as expert in these fields as is Prof. Gates in his own.

The geneticist with an adequate knowledge of clinical medicine, the medical specialist with a sufficient knowledge of genetics, who turns to this book for guidance based on a critical evaluation of the evidence recorded and dealing with a particular pathological condition in which he happens to be interested, may expect to be surprised, even shocked, by the author's lack of familiarity with the particular subject. How could it be otherwise, for it is highly doubtful if there exists any one man who is competent to deal in this way with the whole of medical genetics or, if it comes to that, with the whole of medicine, which in its growth has become fragmented into a multitude of specialties.

When the author is dealing with matters of which his knowledge has been derived from his own scientific activities, his analyses and summaries are precise, cogent and authoritative. But when he turns, as he commonly must, to matters of which his acquaintance is of the slightest, his commentaries are often hesitant, unsure, sometimes definitely erroneous and occasionally positively misleading.

This book should be regarded as a great storehouse of factual information to be used by such as seek recorded observations concerning the modes of inheritance of human defects and derangements, and as are themselves already competent to make use of what they find. It is for the specialists in the different branches of medicine who already have an understanding of modern genetic theory. As such the book is greatly to be welcomed, and for it the author is to be praised. F. A. E. Crew

MIRACLES

Miracles

A Preliminary Study. By C. S. Lewis. Pp. 220. (London: Geoffrey Bles, 1947.) 10*s*. 6*d*. net.

NOT being a trained historian, Mr. Lewis does not examine the historical evidence for 'miracles'; and having never experienced a 'miracle', he has no direct evidence to offer. But as a student of philosophy, he claims to discuss the previous questions, whether 'miracles' are possible at all, and if so, how probable they are, and how the occurrence of a 'miracle' may be proved. In his last three chapters he applies his reasoning to those miracles, acceptance of which is an article of belief for Christians. He defines a 'miracle' as an interference with Nature by super-natural power. If there is no such power beyond Nature, there can be no miracles. Those who think that nothing exists except Nature hold that Nature somehow maintains itself; though some admit that there was a beginning, and that some day "the clock will run down". The alternative is to regard Nature as derivative from some 'one thing', which is basic and original; which created and maintains; what most people call 'God'. The compromise, an indwelling and emergent God (p. 31)—like the other notion that Nature's elements, indeterminate themselves, conform to the 'law of averages'—does not reveal either basis or origin. The issue, therefore, is between 'naturalism' and supernaturalism.

Mr. Lewis argues that no account of the universe can be true unless it leaves it possible for our thinking to be a real insight. The validity of thought is essential, and it cannot be explained by irrational causes. Whereas Nature is quite powerless to produce rational thought (p. 37)—though it can inhibit it—rational thought enables us to alter the course of Nature, as we constantly and consciously do. Each rational thinker thus is—or includes—something independent of Nature, an "incursion" into Nature of supernatural reality—of a reason which exists absolutely on its own (p. 36), a "principle of organization which impels and develops" (p. 41); and this it can do, because Nature (as Heraclitus said) is "logical and congruous with our minds".

Occasionally, Mr. Lewis seems to make a similar claim for all sentient life (p. 165) and even for vegetable life (p. 135); and as to rational life his argument resembles the old principle *omne vivum e vivo*, which is still for physiologists a fact of observation, however firm their faith that it may be refuted some day.

What is demonstrable thus about logical thinking —about truth in all its forms—is true also about primary moral principles (p. 44). What is in question is not the fact that men make moral judgments, but the rightness of them; and rightness cannot result from non-moral events, any more than truth from irrational. Goodness, like truth, has its basis outside Nature. The same argument might be used about beauty, though Mr. Lewis does not concern himself with this aspect of the supernatural—this quality of the divine.

Thus a 'naturalist', whatever else in Nature he can explain, cannot account for himself, or for mankind, in these essential respects. To Mr. Lewis's argument, he can only oppose his profession of faith: "we do not know yet—but some day we shall—that thought can originate from the thoughtless, and life from the lifeless". This, however, is not science but dogma, and many 'naturalists' merely shelve the question. This inability has escaped notice because modern concentration on the perception and understanding of Nature by means of reason, without attention to that by which Nature is perceived and understood, has led to the 'naturalist' illusion that there is no such thing. From the special experts in experiment, untrained in logic and metaphysic, Mr. Lewis appeals to the mystics and philosophers of all ages (p. 109); regarding our present predicament as abnormal and perhaps transitory (p. 53).

From this first contention, that human rationality is in itself (by his definition) a 'miracle'—that the supernatural not only exists but also interpenetrates Nature—Mr. Lewis goes on to ask whether there are any other such interventions. At this point, Mr. Lewis's argument passes from general to particular, from the possibility of 'miracles' to the probability of the greater miracles of Christian belief; and inevitably from logic and metaphysic to historical evidence as to times and places. Not being (admittedly) a historian, Mr. Lewis does not see that criticism of one class of 'miracles' must be applicable to all, from the Incarnation, Joshua's prolonged daylight, and the Resurrection, to the 'calm' of Dunkirk. It is this which has made the most expert historians the most cautious in admitting 'miracles'; and they occur most freely in periods when critical skill was least. Christian theology itself, as Mr. Lewis has seen (p. 85), is one long protest against the misinterpretation of symbols inevitably inadequate.

If a 'miraculous' event is unique, as Nature is itself unique, historical proof is almost impossible. Mr. Lewis compares the recovery of a missing episode from a novel or a symphony: if what is found 'makes sense' of the whole composition, its genuineness becomes very probable, and Mr. Lewis devotes the rest of his book to this view. He might have followed the great theologians further. But appropriateness is not proof. John L. Myres

ONSLAUGHT ON A SUPERSTITION

The Royal Art of Astrology

By Robert Eisler. Pp. 296+17 plates. (London: Herbert Joseph, Ltd., 1946.) 18*s*. net.

For the convenience of astrologers "Whitaker's Almanack" for 1947 carefully records the "hour when the Sun enters each Sign of the Zodiac"; Eisler describes in his opening pages how rampant astrology is. He is obviously anxious to destroy this present "stale, superstitious residue", and perhaps his historical survey often forgets his own dictum that this once "glorious philosophical attempt" founded modern astronomy and cosmology (pp. 28, 262). He connects present astrology with "widespread intellectual destitution", and includes with it many pre-critical survivals, such as belief in the "spontaneous generation of life" or in "causes and effects" (pp. 11f, 260f).

Astronomy can forecast an eclipse; astrology can use astronomical calculations, but its own peculiar predictions from horoscopes about the War give Eisler a chance. Italy's entry was not foreseen: an unread message in the stars, however, is less damaging than a message misread. The stars were misread about Sweden, for some astrologers expected Hitler to attack her. Astrologers constantly predicted no war until there was one; then they constantly predicted its end before the finish came. Eisler deduces that modern astrologers try to please their clients by comforting predictions (pp. 21ff). Even if war-time predictions are not fair samples, they are significant. Some astrologers, fairness should add, affirm the old aphorism, the stars incline and do not compel: they impose temperament, not specific destiny. Astrology is vulnerable enough to make undiscriminating arguments unnecessary.

The zodiacal signs cannot derive their astrological significance from accumulated Chaldean and Egyptian experience, Eisler affirms, because they were originally unimportant (pp. 87–110). "Precession" provides "one of the most decisive arguments" against astrology by involving it in absurdities. Eisler notes a typical absurdity "in most modern text-books of astrology". A child born, or conceived, when a certain sector of the zodiac is rising has "Taurine" qualities. Aries is there now, but Taurus was there two thousand years ago, and left his power in it (pp. 110–22).

The stars and planets did inflict one stupendous consequence on men—a medley of beliefs in their presumed effects which determined astrological lore more than sober induction. Eisler uses modern research, the study of old astrological records, for example, to probe the growth of astrology. Inferences about astrological inferences may be mistaken; but Eisler's survey reveals the workings of the human mind and their astrological consequences. His onslaught seems to have precipitate consequences at times. He seems to ignore, for example, that Eudoxus and some others after him regarded the "spheres" as non-physical geometrical conveniences (pp. 33ff). He calls the "hypothetical 'attraction' " of Vitruvius the ancestor of Newton's "mythical 'force' of 'gravitation' ", though Newton did not regard "forces" as actual agents (p. 237).

If Mars derives his astrological reputation from his reddish hue, and Saturn, the "leaden planet", his from his "slow, constant movement", astrology has embodied some wild analogies. It embodies another, if those born under a slowly rising sign live long (pp. 103, 162f, 169). Eisler discusses many wild analogies that have suffused astrology. Imagination has grouped the stars into constellation-pictures, connected them with myths, and drawn astrological deductions. Scorpio, for example, indicates his influence by appearing in the horoscopes of Hitler and Mussolini, though Goethe and Horace had the same ascendant sign (pp. 102f). Historical evidence, Eisler replies to modern defenders, shows that the signs were not named *after* their actual effects had been observed (p. 115).

Tycho Brahe, Eisler says, clung to geocentric astronomy because a central earth is essential to astrological divination (pp. 210, 230). In 1653, Thomas Steele does not fear Copernicanism because astrology can use any valid system of calculation; for an extreme relativist to-day mathematical convenience decides between heliocentrism and geocentrism.

Interesting items include souls and stars, the egregious horoscope of Christ, the "houses" of the planets and the creation of the world, astrological disregard of the velocity of light, the adoption of Uranus as the patron of machinery, and, like odd grains of wheat in much chaff, some actual lunar effects.

There is no index—perhaps because there is so much to compile. The chapter headings, however, are reasonably good guides. Interesting plates and figures are explained in Chapter 33. The last chapter contains a useful bibliography—with comments by the author. Joshua C. Gregory

THEORY OF RADIO ANTENNÆ

Antennæ

An Introduction to their Theory. By J. Aharoni. Pp. viii+266. (Oxford: Clarendon Press; London: Oxford University Press, 1946.) 25s. net.

THE theory of radio transmitting and receiving aerials is by no means an easy branch of electromagnetism. Aerial theory forms the bridge between the theory of circuits and transmission-lines on one hand and the theory of wave-propagation in space (that is, space more or less free from boundaries) on the other. Aerial theory thus has to face the difficulties of both fields without the simplifications of either. Useful progress largely depends on knowing when, how and how far to permit infiltration of simplifications from both sides. Progress has not therefore been easy, and misunderstandings have been common. However, the widespread development of aerials for radar and radio communication during the War, sometimes along novel lines, has served to clarify the issues involved. The time is therefore ripe for setting down on paper connected accounts of the progress so far made in the development of aerials, and of aerial theory in particular.

This book is, for the most part, a connected account of aerial theory as it had appeared in the technical press before the curtain of war-time secrecy fell. The treatment is mathematical, and the book is scarcely suitable for readers who are not reasonably at home with a mathematical presentation. But the treatment is not academic. What is written seems to have been dictated, not by a desire to do mathematics, but by a desire to describe in mathematical language the basic physics of aerials that should be understood by any radio engineer whose job involves getting down to fundamentals. The book does not deal with elaborate, fancy, or novel aerial systems. It deals almost exclusively with fundamental theories of elementary aerials: the loop, the Hertzian dipole, the half-wave dipole, the full-wave dipole and dipoles of intermediate lengths.

It may be doubted whether the arrangement and subdivision of the book is as good as it might have been. The book is divided into only three chapters, of which the second consists of nearly sixty per cent of the whole. The reader is consequently apt to find that, before he has adequately reflected on one aspect of the subject, he is already engulfed in another. In spite of this, however, the arrangement is not confused, and there is no serious difficulty in finding what one wants from the table of contents. Whether the arrangement adopted places the simplest things first, and whether the approach used is always the simplest available are perhaps matters of opinion.

In each principal aspect of the subject the author has followed fairly closely the original papers that he quotes. For this there is much to be said, though a little more criticism in places would have been welcome. Hallen's treatment of the ends of an aerial is, for example, rather shaky, but the author reproduces Hallen's original argument with apparent confidence. Even so, however, it is very convenient to have Hallen's theory available in this book, since the original paper is in a somewhat inaccessible journal. In addition to Hallen's theory based on an integral equation for the current-distribution, the book includes Schelkernoff's theory based on a wave-guide treatment of the biconical horn, theories dealing with prolate spheroidal conductors, Brillouin's "back E.M.F." method for calculating input-impedance for aerials having prescribed current distributions, as well as the usual treatment of the polar diagram and the radiated power by the Poynting vector method.

Since the author seems to have set out to collect in book form mainly the standard papers on fundamental aerial theory, it would perhaps be unfair to criticize him for making no serious use of the concept of field impedance. Field impedance is equally applicable to transmission lines, to aerials and to wave propagation in space, and so is well suited for integrating all of these phenomena into a single picture. Consideration of field impedance leads one to regard the operation of a straight thin aerial somewhat as follows. Imagine a geometrical cylinder drawn coaxial with the aerial wire and having a radius equal to, say, the geometric mean of the radius and length of the aerial wire. Let this cylinder be terminated by planes through the ends of the aerial perpendicular to the wire, and consider the regions inside and outside the cylinder separately. Outside the cylinder the field may be thought of as that due to a prescribed sinusoidal distribution of current along the aerial wire, and on this basis the field impedance looking normally out of the cylinder may be calculated. Inside the cylinder, the field departs from that due to a sinusoidal distribution of current, especially near the aerial wire itself, and this is how the boundary conditions at the surface of the wire are satisfied. Inside the cylinder the field may be thought of as that in a concentric transmission line the inner conductor of which is the aerial wire and the outer of which is the geometrical cylinder; the impedance per unit length of the outer is that calculated from the field outside the cylinder as already described. This is quite a useful and flexible way of effecting the all-important link between the transmission line approach to aerials and the approach based on a prescribed sinusoidal current-distribution. In particular it explains why, in the conventional application of the back E.M.F. method, it is possible to integrate what is undoubtedly the wrong quantity along the aerial wire and yet get something extraordinarily like the right answer. The integral should in reality be taken along the outer of the concentric transmission line described above, the radius of which tends to zero with the radius of the aerial wire, but more slowly. These points, and others that follow from the same line of argument, are not made in the present book. For this reason it may be doubted whether the book gives a good lead for the future of aerial theory, although it undoubtedly describes the past quite well.

For the future of electromagnetic theory in general there are two respects, however, in which the book does give a good lead. Although the author makes no serious use of field impedance, he not only uses circuit impedance but also gives, early in the book, a better description of what is involved in the concept of reactance than seems to have appeared in any previous book on the theory of the electromagnetic field. In addition, all equations have been written in rationalized universal units (in particular rationalized metre-kilogram-second-coulomb units), thereby facilitating physical and engineering interpretation. Both these features symbolize the complete unification which has been taking place during the past decade, and is still going on, between the theory of electrical circuits (dealing largely with interchange of stored electromagnetic energy) and the theory of electromagnetic waves (dealing largely with propagation of electromagnetic energy and developed in the first instance particularly for optics). It is a pleasure to see that post-war books on this subject from the Clarendon Press are displaying the new spirit in electromagnetic theory.

To sum up, it may be said that, as a connected account of classical contributions to fundamental aerial theory, the book is well worth reading and well worth keeping to hand. H. G. BOOKER

BRITISH BUTTERFLIES

Butterfly Lives

By S. Beaufoy. Pp. 128. (London: Wm. Collins, Sons and Co., Ltd., 1947.) 12*s.* 6*d.* net.

THIS book of nearly two hundred pictures will give pleasure to many who are interested in animal photography.

Mr. Beaufoy has illustrated, in all stages, twenty-two of the sixty-eight British butterflies, representing every indigenous family, though the distribution of the species selected is rather uneven. Thus there are seven Nymphalidæ, five Pieridæ, five Lycænidæ, but only two Satyridæ: the others are the 'Duke of Burgundy', a 'Skipper', and, of course, the 'Swallow Tail'. We feel that it would have been a more notable feat to show more of the Satyridæ with which the public is less familiar, and omit some of the well-tried favourites.

Dr. Ford points out in his preface that the species are selected to show the characteristics of every indigenous family, and these are indeed brought out. We particularly appreciate the photographs of eggs, of which the shape and sculpture proper to each are beautifully shown. The figures of very young larvæ are a welcome novelty. Most people are familiar with a series of pictures of a butterfly emerging from the chrysalis: less often studied is the remarkable escape of the freshly formed pupa from the hampering larval skin, as shown in a series of six pictures of the small Tortoiseshell at this crisis in its life-history. This seemed to me one of the most instructive series in the book.

Lycænid pupæ are less successfully figured: perhaps a little less magnification would have been better suited to their rather shapeless obesity. On the other hand, the picture of the pupa of the 'Duke of Burgundy' is particularly revealing. The fragrant osmeterium of the larva of the 'Swallow Tail' is well shown.

The letterpress adequately discusses the illustrations, with a few notes on habits, etc.: but the book is, primarily, a picture book. The photographs are certainly "from life", but so is a photograph of a tiger in a cage, and the phrase must not be taken always in its fullest implication. Mr. Beaufoy freely admits that, in photographing butterflies, "really good results, out of doors, are rare", and tells us how, with artificial lighting, he provides "a suitable" setting of foliage or flowers. However, as Mr. Beaufoy's object was "to depict the detailed characteristics of the different species" the question whether, for example, the beautiful picture of the variety of the 'White Admiral' on bramble blossom was taken within or without the studio need not worry us unduly. There can be little doubt about the 'Swallow Tail' feeding from *Buddleia*! Two errors "Aphantophus" (p. 10) and "Lycænidine" (p. 79) should be corrected. G. D. HALE CARPENTER

FIREPROOFING OF FABRICS

The Fireproofing of Fabrics

By J. E. Ramsbottom. Pp. vi+121+11 plates. (Department of Scientific and Industrial Research; H.M. Stationery Office, 1947.) 2*s.* 6*d.* net.

ONE of the major defects of most textile fabrics is their inflammability, and as early as 1638 attention was directed to the use of clay and plaster-of-Paris to reduce the fire risk of canvas used in theatres, while in more recent times the need for fireproofing is periodically emphasized by the comments of coroners on the inflammability of children's flannelette garments. Fireproofing is also of considerable importance to the Services, and in 1930 a preliminary account of investigations carried out at the Royal Aircraft Establishment at Farnborough was given in the second report of the Fabrics Co-ordinating Research Committee.

The present publication is a description of further studies by Dr. Ramsbottom and his colleagues on the subject of fireproofing, together with a new presentation of some of the information given in the earlier report. The object of the investigation was two-fold—to examine the effectiveness of the various fireproofing processes described in the technical and patent literature, and to develop a theory of fireproofing. A treatment which is to be successful commercially should have no adverse effect on the material, and this aspect must be taken into account when assessing the relative merits of various methods. The proofing of kapok, for example—a problem which has been considered in some detail—must not affect the buoyancy of this material. Work of this type has necessitated the development of new methods of experimentation, and the description of these constitutes a valuable guide for other investigators.

The theoretical aspects of fireproofing were first studied by Gay Lussac in 1820, but until recently it was not possible to account for the differences in effectiveness of closely related compounds. As a result of Dr. Ramsbottom's work, however, it may be concluded that fireproofing agents are in general effective because they act as catalysts which modify the changes accompanying the thermal decomposition of cellulose. This hypothesis, which is elaborated in detail for both soluble and insoluble fireproofing agents, will serve as a useful basis for further investigations.

Dr. Ramsbottom's monograph is not a text-book of the usual type—it is primarily an account of his own experimental work—and is written clearly with the detail associated with original contributions. It is authoritative except when dealing with the relative inflammability of various textile materials. This section could with advantage be modified; certainly the term 'artificial silk' should not be used, and some indication should be given of the different fire risks associated with the many types of modern rayons.

Although the booklet does not deal with all aspects of fireproofing, it is an important contribution to the subject and should become a standard work.

A particularly useful feature is a comprehensive list of fireproofing reagents, and the suggestions of the authors as to suitable methods of fireproofing will be of great assistance to practical men called upon to produce fireproof goods. C. S. WHEWELL

Invertase

A Monograph. (Scientific Report Series, No. 4.) By Prof. Carl Neuberg and Dr. Irene S. Roberts. Pp. ix + 62. (New York, 5: Sugar Research Foundation, Inc., 52 Wall Street, 1946.)

THIS useful monograph on invertase by Prof. C. Neuberg and his daughter, Dr. I. S. Roberts, is a Scientific Report of the Sugar Research Foundation, Inc., of New York. As might be expected from so eminent an investigator as Prof. Neuberg, the monograph gives a succinct and authoritative account of the properties, sources, and modes of preparation of one of the earliest known enzymes. The methods of purification of invertase by adsorption techniques, first used with success by Willstätter, and by precipitation procedures are described in some detail.

Invertase was discovered more than a hundred years ago, and while its study has played an important part in the development of our knowledge of enzymology, its industrial importance, especially in the sugar industry, has not been perhaps so well recognized. Invertase was employed extensively in the preparation of molasses for the supply of sugars to alcohol plants during the times of great urgency when alcohol was required for making synthetic rubber. It plays an important part in the manufacture of confectionery. Biochemists will do well to read this monograph, which summarizes recent literature (405 references) on the subject.

It is unfortunate that the monograph is not entirely free from error. Thus the statement that Quastel and Yates have reported on the inactivating non-reversible influence of both basic and acid dyes is incorrect. These authors (*Enzymologia*, 1, 60; 1936), on the contrary, have shown that both basic and acid dyes combine reversibly with invertase according to mass action laws. In fact, the equilibrium between invertase and acid and basic dyes provides an excellent example of the reversible combination between the ions of an enzyme and those of organic inhibitors such as the dyes. The equilibrium constants of the enzyme–dye combinations were determined, and these results, together with other facts, led Quastel and Yates to the suggestion that invertase acts as a *zwitterion*, the oppositely charged groups of which may be bridged by sucrose when this is present as substrate.

The Soochow Astronomical Chart

By W. Carl Rufus and Hsing Chih Tien. Pp. v+24+2 plates. (Ann Arbor, Mich.: University of Michigan Press; London: Oxford University Press, 1945.) 14*s.* net.

THIS chart and the text appearing with it constitute instructions for an Emperor and were prepared in A.D. 1193 and engraved in stone in 1247. More than thirty years before they were engraved the capital had been moved from Peking to Kai-Feng Fu, in Honan, but in 1267 Peking was restored as the capital. We are informed in the text that before the Great Absolute had unfolded itself the three primal essences, heaven, earth, and man, were involved within it. The Great Absolute evolves into the sun and the moon, divides into the five planets, arranges in order as the twenty-eight mansions, and meets to form the directors (the Plough) and the circumpolar stars. In the description of the sky the equator is called the Red Road, the ecliptic the Yellow Road, the moon's path the White Road, and the Milky Way the River of Heaven. The planets are the essences of the five elements—wood, fire, earth, metal and water—these elements constituting the planets Jupiter, Mars, Saturn, Venus, and Mercury, respectively. A description of the star map, the purpose of which is astrological rather than astronomical, is given on pp. 8–10. The asterisms follow the traditional oriental pattern—terrestrial beings personified, especially the Emperor, his court, and numerous officials, which differ from the predominant mythical heroes of the West, including supernatural or superhuman personages.

The authors must have spent much time and energy on the production of this work, which will interest all who study the history of ancient constellations.

The Mentally Ill in America

A History of their Care and Treatment from Colonial Times. By Albert Deutsch. Pp. xvii+530+8 plates. (New York: Columbia University Press; London: Oxford University Press, 1946.) 26*s.* 6*d.* net.

"THE Mentally Ill in America" outlines the history from the earliest times of the attitude towards the insane of their fellow men, particularly in the United States. The author has spent a great deal of time on literary research, and the result has well repaid the time spent. Benjamin Rush, Dorotha Dix and Clifford Beers, names very familiar to English-speaking psychiatrists and others concerned in the care and treatment of the mentally sick, come in for prominent mention, as well they deserve. The detail given is extraordinary and makes a fascinating study; but the author presents mental hygiene with a stupendous task when he posits the goal toward which mental hygiene must strive as "a world of peace and freedom, from which the twin specters of war and insecurity will be banished, a world of equal opportunity, where people will be freed from stunting inhibitions and guilt feelings arising from outworn prejudices and taboos. . . ." What an objective, and how hopeless it seems in the present state of society the world over! G. W. T. H. FLEMING

A New Arithmetic

By A. W. Siddons, K. S. Snell and E. H. Lockwood. Part 1. Pp. vii + 184. 2*s.* 9*d.* Part 2, including Numerical Trigonometry. Pp. viii + 210. 3*s.* Part 3, including Numerical Trigonometry. Pp. vii + 151. 2*s.* 9*d.* Notes and Answers for A New Arithmetic. Pp. ii + 90. 5*s.* (Cambridge: At the University Press, 1947.)

THIS new arithmetic consists of three parts, published separately. Part 1 revises the elementary processes of arithmetic, including mensuration, and includes a chapter on statistical graphs. Part 2 begins with the use of four-figure tables of squares, square roots, reciprocals and logarithms. Through the elements of mensuration it leads to numerical trigonometry. Part 3 is devoted to further work on trigonometry, mensuration, more difficult percentages, compound interest, civic arithmetic, stocks and shares, followed by an introduction to statistics for post-school certificate reading.

Carefully graded sets of examples are provided, together with many revision papers. A commendable feature is the emphasis laid upon the proper use of English in writing out the solutions.

Teachers' editions are published separately for Parts 1 and 2 giving notes and answers; the latter are not provided in Parts 1 and 2, but are given in Part 3.

SCIENCE IN WAR AND PEACE*

By Sir HENRY DALE, O.M., G.B.E., F.R.S.

THE officers and Council of the British Association have naturally wished that this meeting should take special note of the emergence of science, in Britain as in other countries, from its abnormal concern with war, and its return to the service of peace. To rally and to give direction to the thoughts of the members and of the sectional officers in this general sense, the phrase 'Swords into Ploughshares' was suggested, and adopted by the Council, as a motto for the meeting. Even in its most obvious meaning, of the direct adaptation to peaceful uses of the practical results of researches made to meet the demands of war, or forced into rapid fruition by the heat of its urgency, the metaphor will find abundant application in this week of discussions. Let me choose a few, almost at random, for mention now.

How many decades of research do you suppose, undertaken in response to no stimulus stronger than the desire to add to the resources of peace, would have been acquired for those developments of radar, which were achieved in a few years under the imminent threat and the realized peril of war ? It is certain that the scientific activities of peace had never witnessed anything like the intimate collaboration of British and American physicists and engineers, which finally played so important a part in giving full effect to this triumph of science in the service of war.

Aeronautical science, having received a great stimulus in the First World War, and having undergone a steady development in the intervening years, sprang again into a phase of headlong progress under the threat and the experience of the Second World War. Now we wait to see what will be the effects, on speed and safety in peaceful transport, of gas-turbine engines and jet propulsion, of stratosphere flight in pressure cabins, and of the fundamental changes in aircraft design, which are all still under rapid development.

Sir Alexander Fleming had encountered the first evidence for the existence of penicillin and described the general nature of its action in 1929, ten years before the War began ; but, during that interval, its interest had remained little more than that of an item in the natural history of moulds and bacteria. Sulphanilamide and its derivatives, meanwhile, had opened a new vista of chemotherapy for the bacterial infections, and gramicidin had provided an example of a natural antiseptic, an 'antibiotic' of practical potentialities ; but exploration, in this field also, was to wait for war's demands to give it a full and urgent acceleration. And we cannot doubt that the wider survey by Sir Howard Florey and his team, which led them, in 1939, to take penicillin down from the shelf of sound but unexploited observation, for the new study which brought it so rapidly into practical use, owed some of its stimulus to the gathering menace of war. We may certainly assume that the lavish character of the industrial research and enterprise, which then so quickly overcame the difficulties of manufacturing penicillin on a large scale, was chiefly due to recognition of the part which it would play in the conduct of the War. This industrial production, again, made penicillin, and then several penicillins, more rapidly available for the purely scientific investigation of their structures. Here, again, the conditions of peace have never produced such a remarkable co-operative effort of research as that in which teams of some of the leading chemists of Britain and of the United States pooled their results, solved the difficult structural problem with what, by normal standards, would have been an astonishing rapidity, and even, in the case of one of the penicillins, confirmed by synthesis the structure to which the less-direct evidence had pointed.

French, British and Italian investigations had all contributed to the discoveries which had identified the blood parasites causing the malarial fevers, and revealed the manner of their transmission by mosquitoes, all before the present century began. Little more than detailed advance, on the other hand, had been made in the curative or preventive treatment of malaria by medicines since the seventeenth century. Cinchona and its chief alkaloid, quinine, had continued to provide the standard medicinal treatment, although, between the Wars, the research enterprise of German industry had produced two new artificial remedies. One of these, indeed, known as atebrine, and later in Britain as mepacrine, was understood to be comparable in action to quinine, though there had been no sufficient inducement to its extensive trial as a substitute. It was fortunate, then, that, as a military precaution, the effective manufacture of mepacrine had been undertaken in Britain, and then in the United States, before Japan seized, in the East Indies, the source of most of the world's supply of quinine. Under the continued stimulus of war's demand, again, a new campaign of chemotherapeutic research was opened in both Britain and the United States, to seek yet better remedies than quinine or mepacrine. Again there was a co-operative exchange of information and materials between the workers in both countries, and the investigation was conducted on such a scale and with such organisation of effort as had never been contemplated in peace. In a surprisingly short time came reports of new lines of development showing great promise ; and a British one of these has culminated, so far, in the discovery of paludrine, a synthetic antimalarial substance of a new type, more effective, and at the same time much freer from harmful accessory activity than quinine, or mepacrine, or any other of its predecessors.

The needs of war, again, soon presented to engineering, on one hand, and to physiology and experimental psychology on the other, a group of practical problems arising from the unnatural conditions of physical and mental stress to which men were exposed in the constantly developing machines of modern warfare, as well as from the extremes of climate and the deprivations to which they were subjected by military necessity or accident. The researches which were framed and conducted, in response to these varying demands, have produced a great volume of new knowledge concerning a variety of conditions which favour or hinder the different activities of man's body and mind, and their resistance to the influence of fatigue.

---

*Substance of the Presidential Address to the British Association for the Advancement of Science delivered at Dundee on August 27.

Not all the uses of war-time discoveries in peace will depend on applications so direct and obvious. There are examples already, and it is most likely that more will appear, of inventions made with no purposes but those of war, which have found peaceful use in directions entirely unforeseen. For example, an artificial chemical substance, di-isopropylfluorophosphonate, now commonly known as D.F.P., was first made and studied in Britain, as an active member of a poisonous series, known to be under trial in Germany as potential weapons of chemical warfare. The actions of D.F.P., some of them unpleasant enough, were found by workers in Britain, whose results were later confirmed by colleagues in the United States, to be due to its power of annulling the action of cholinesterase—an enzyme widely distributed in the animal body, and playing an important part in relation to the transmission of a number of nervous effects. D.F.P. was never used, in fact, as a chemical weapon ; but the action which might have led to such employment has already made it, not only a most interesting and valuable tool of physiological research, but also, according to recent news from the United States, an invaluable remedy, when suitably administered, for the dangerous paralysis of the intestine which may follow an operation. So the wheel has come full circle, and the sword, forged as a lethal weapon, finds use, not only as a ploughshare of peaceful research, but even as a shield for threatened lives.

The sectional meetings during the week will certainly have under discussion many more of such direct applications and extensions of discoveries and inventions made in war to the ordinary needs and purposes of peace. These will constitute, however, only a part, and very likely not the most important part, of the incidental and compensating gains of science itself, and of mankind through science, from this participation in the researches required by war. Scientific research may expect to obtain, from inventions thus made for special and quite unrelated purposes, new tools and facilities for the general advancement of natural knowledge over wide ranges. The development of rockets as weapons of extreme range, for example, may provide means for obtaining data of physical conditions, at altitudes from the earth's surface previously far beyond the reach of scientific exploration ; and the great advances made in aerial photography will certainly find application for purely scientific surveys of various kinds, over land and sea. And, apart from many and great additions of this kind to the physical and technical resources available to research, there will be lessons to be learned from war's experience of the methods of planning and organising research, of the recruitment of special research teams, of the value, for the rapid attainment of a particular objective, of co-operation on a national and, as in cases which I have quoted, on an international scale.

Scientific method has had new opportunities of demonstrating its value in the range of the so-called 'operational' researches, in which, for the first time in any war, a largely successful effort was made to collect, and to subject to scientific analysis, accurate data of the performance of new weapons, and of the outcome of new methods. All such experiences in war will have left lessons which may have value in peace, to science in the pursuit of its normal objectives, and to the world at large in a new understanding of what science can be expected to do, and of the kind of aid it can offer towards the solution of suitable problems.

While we may well be eager, however, to ensure that science and those who cultivate it should thus retain and exploit the lessons of value which they learned in their service of war, it may be of at least equal importance that they should, with all rapidity and thoroughness, forget others which ought to be discarded. It is scarcely to be doubted that, to many men of science, the War brought opportunities for research under conditions which made it, in various ways, and in spite of the strain and anxiety of the time, more immediately attractive than any that they had previously encountered. Comradeship, effective even across some national boundaries, in work for a great cause, without thought of personal credit or recognition ; an escape, perhaps, from indecision concerning the scientific worth or soundness of a line of personally chosen research, and from anxiety as to material resources for its pursuit, into a world of authority and planning, of problems posed by actual emergencies, of practical issues and tangible results, and of facilities without restriction ; and a sense withal of high duty performed for the future of his country and of the world, by the use of a man's own special knowledge and skill, and not always without danger—duty as clear and unquestionable as others could only discharge by a sacrifice of all their normal instincts and interests and, for many, of life itself—all these conditions of scientific war service may have given to many a man a different kind of satisfaction from any which had come to him from the normal experience of a man of science in peace.

I suggest that there may be danger to science from a tendency to transfer too easily and completely, to the activities of peace, the attitude to research and the traditions of its conduct which have been acquired during six years of such war experience.

I am not, of course, speaking just now of the perversion of science which war research involves through its particular concern with the means of slaughter and destruction. For the moment I am concerned with the fact that the response to war's demands has led the majority of scientific workers of Great Britain to devote nearly the whole of their thoughts and efforts, during six years or more, to practical problems presented to them for rapid solution. There must, indeed, be many younger men who have had little experience of other kinds of research than that which has been thus directed and restricted to near and practical objectives, and carried out under a pressure of urgency. From Government organisations and industry, awakened by war's experience to a fuller awareness of what science can do for them under such conditions, it is not likely that encouragement will be lacking for a continuation of similar activities into peace. I myself, indeed, have been bringing to your notice the claims of lines of research which had proved fruitful of practical result for the purposes of war, to be continued and developed now, with a new orientation, to serve those proper to peace. I must make it clear, then, that it is far from my intention to suggest a predominance, in the programmes now to be shaped for science, of such transference to peaceful uses of the research enterprises of war and the methods by which they have been conducted.

Does anyone doubt that, to enable science to render its best service to mankind, we need now to take a long-range view and to give our first care to the extension of fundamental knowledge, unconstrained by aim at any practical objective ? I am not here concerned to advocate, or to defend, either of the rival philosophies, postulating the advancement of pure knowledge on one hand, or the material betterment of man's lot in the world on the other, as the ultimate true motive of the scientific effort. I believe that it would be admitted, by partisans of either, that research which seeks only to advance pure knowledge commonly leads, in the end, to the widest practical developments; and examples are to be found of the contrary, when practical researches are conducted under conditions which leave full freedom to follow fundamental issues, as these present themselves. The concentration, however, of practically the whole of a rapidly growing scientific effort on practical applications and developments, such as the War has witnessed, might find instructive analogy in a rapid and even reckless extension by a commercial undertaking of its trading enterprise, without care to conserve and proportionately to expand its resources of working capital. In theory I think that this is generally recognized, and I am not assuming that any of the different authorities which now provide material support for science in peace will hesitate to give generous encouragement to fundamental researches. My fear is rather that we men of science may find it difficult to shake off quickly the spendthrift habit in research, the policy of trading for quick returns, which six years of war experience may so easily have fostered.

There are other directions in which, I suggest, we should be alert and watchful against too ready an acceptance of lessons learned in war research as applicable directly to the needs of science now. The world never possesses at any time too many men of the highest kind of qualification for research in science—men who, by their own personal effort and achievement, can exert a determinant influence on the rate and the direction of the advance of knowledge into the unknown, and can open new fields of science to detailed exploration by others. There may be men of that type who found that, in the years of war, they could give their best service to science, as well as to the nation and to the cause for which it stood and fought, by organising and planning researches for teams of men with narrower experience and outlook, and by bringing scientific methods to bear on problems of military policy. I believe that scientific services of that kind, rendered in war, have earned far more than they will ever receive in the way of acknowledgment; but I venture to voice a hope that men with the rare, creative ability that science needs now for the resumption of its normal progress, whose influence and example are needed in the schools for the inspiration of those who will follow, will not too readily assume, or too easily be persuaded, that their best service to science will still be rendered by planning and organising, or by bringing scientific ideas to bear upon policy. Here, again, I believe that, under conditions now to be faced, the building up of our scientific capital of fundamental knowledge by those who have the creative gift should have a prior claim over its practical exploitation and the cultivation of its political influence.

There are many, I think, who will be remembering with me the mood which prevailed among men of science when the First World War ended in 1918; how we looked forward then with eager hope and confidence, ready to write off the losses and delays which those four years of war might have inflicted on science, and determined to conserve for it all that could be counted as gain. The role of science in that War had, indeed, been relatively small. For the general body of men of science it had begun on a basis of opportunist intervention or response to special appeal, to deal with emergencies as these arose, the country's scientific reserves being called upon tardily and never completely enrolled. And, when victory came in 1918, the men of science, with few exceptions, were able quickly to escape from war's abnormal duties and commitments, and to return rejoicing to the free air and the wide horizons of science, as they had known it earlier in peace. Lessons had been learned then, as now; the Government and public opinion had gained a new conception of the support of scientific research as a national investment; but thoughts of war, and of its claims on science, receded rapidly then into the background. And although what was to have been a permanent peace proved, in the event, to be less than two decades of an uneasy armistice, with the shadow of another war then rapidly encroaching, what a wonderful new flowering of science was witnessed in that short interval!

Think of the speed and completeness with which our ideas of the universe of matter, of atoms and of the ultimate, subatomic particles, of elements and their mutability, were then being recast; of the transformation, as rapid and impressive, of conceptions of the life process and its physico-chemical background by the advances then being made in organic and physical chemistry, with biochemistry in ever more intimate alliance with them; of the new worlds of knowledge and ideas which were then being opened by the linking of genetics and nuclear cytology, giving a physical basis to the complexities of heredity; or of the first systematic study of the properties of ultramicroscopic viruses, linking, in a manner still mysterious, the characters of matter in macromolecular solution with those of the smallest living and self-propagating organisms. From all these, and from fundamental advances of comparable rapidity and significance in almost all fields of scientific activity, rich harvests of new development and extension were continuously being reaped, by medicine, agriculture, industry, and all branches of applied science. Never, surely, in all previous history, had science surged forward with such impetus as in that interval of years when, in spite of recurrent economic and international crises, a lasting peace seemed still not beyond hope, and a golden age, for a world entering the scientific era of its history, a not impossible aspiration. And, for science itself, one of the points of brightest hope and encouragement was to be found in the steady rebuilding in that interval, in spite of initial obstacles and discouragements, of a true world community of science.

We know how tragically that interval of optimism and of free progress in science, so rapid and so various, came to an end. We cannot expect or even encourage a quick revival of that earlier mood. We are faced now by the contrast between the parts played by science in the two World Wars. In that from which we recently emerged, science, no longer a mere accessory, has moved right into the centre of the picture; and by a process of which we may, perhaps, find the tentative beginning in 1915, with the first use of chemical warfare as a weapon of mass slaughter and disablement, the belligerent use of science has undergone a rapid transformation, turning it into a weapon and a combatant in itself, released from afar for the undiscriminating infliction of death and destruction, at rapidly growing ranges and on an ever increasing scale. The atomic bombs on Hiroshima and Nagasaki represent, of course, the proximate peak of this development, so far as it has yet been made known; but nobody can suppose them to be the climax of disastrous achievement, if the nations should persist in the desperate project of using further advances in this, or in any other department of science, to prepare in secret, each to excel or to anticipate others in perfecting the means of annihilation. Does the world need yet to be warned as to the end of such a policy? If so, we men of science must continue, against any reluctance to repeat and to insist, to proclaim the danger, and our hatred of the perversion of science to its creation.

Meanwhile we have our own problem of the effect of such a position on the prospect of science itself. For a devotion so complete to the service of war as that which was given in recent years has involved many men of science during its progress in obligations of secrecy entirely new to their experience; and there are important sections of scientific activity which have not yet been able to escape from these trammels. That concerned with the release of atomic energy, with all the side-issues into new lines of scientific progress which that gigantic war enterprise might have made, and will yet, we hope, make available, provides the most conspicuous case. This might, indeed, be regarded as epitomizing, or presenting, by way of an extreme example, the way in which science in peace may inherit opportunities from developments for which war alone could have set the scale and provided the momentum, and the threat to the freedom of science which may be entailed by the same inheritance. Though the scientific basis for its prediction was available in 1939, before the new War broke out, nothing but war, and the need to anticipate a danger of such magnitude in war, could have brought about an effort on the scale needed to convert the release of atomic energy by a chain-reaction from theory to practical reality in a few years. If peace had remained unbroken, the world might have had to wait for many decades to reach a point of such possibilities, for new departures and rapid advances in a whole range of fundamental sciences. War immensely accelerated the presentation of this opportunity to science; but, in doing so, compromised the peaceful use of it by the hideous threat of its further abuse in war. Science, then, finds itself facing a situation in which hope and frustration contend; the need to make the world safe, and the delay of agreement on the means of doing so, clog wheels of science which should now be turning freely for the enlightenment of mankind and the enrichment of human life, many years, perhaps many decades, before they could have done so if the War had not yet come.

How then are we men of science to deal with such a situation? With unquestioning loyalty to all our obligations—that first and foremost; but then also, I would urge, with a resolute watchfulness against any encroachment, on activities proper to peace, of a secrecy which we accepted as an abnormal condition in war, and with a determined effort to accelerate the liberation of science from its entanglement. In the universities in particular I hope that we shall be able to ensure that the men of science of the near future will grow up, as we their predecessors did, in an atmosphere of scientific freedom, and be ready to accept, in their turn, the duty of standing, at need, in the defence of science in its full integrity. And I hope that we can keep as the constant aim of our endeavour, in spite of all that might excuse discouragement, the revival of an intimate brotherhood of the men of science of all nations, working together in full confidence, once more as a world community.

SUMMARIES OF ADDRESSES OF PRESIDENTS OF SECTIONS

EARTH, STARS AND RADIO

During the year 1947 we are celebrating in Great Britain two important jubilees, one technological and the other scientific. It was in 1897, fifty years ago, that Marconi, the young Italian inventor, gave a decisive demonstration of 'telegraphy without wires' to Sir William Preece, who was then engineer-in-chief of the British Post Office. It was also in 1897 that the Cambridge professor of experimental physics, Prof. J. J. Thomson, made the first public announcement, at an evening discourse at the Royal Institution, of the existence of the electron as an independent entity. The technological development of radio from those early beginnings has had most important scientific consequences. Correspondingly, the scientific discovery of the electron, although important in the first instance because of its bearing on atomic theory, has had profound technological consequences. Indeed, it is scarcely possible to cite better examples of the mutual influence of fundamental science and technology than the developments which have sprung from those two great events of fifty years ago. These developments form the subject of the presidential address by Sir Edward Appleton to Section A (Physical Sciences).

The progress of radio as an agency for exploring the universe has followed directly from two electronic developments, namely, the thermionic valve and the cathode ray oscillograph. With the thermionic valve it is possible to generate radio waves of almost any wave-length. Moreover, such waves, if sufficiently short, can be emitted or received in any desired direction. It is also possible to arrange that their emission takes place in spurts, or pulses, which can be detected again if the waves are reflected by any natural agency in space. The cathode-ray oscillograph can, on the other hand, be used for the measurement of short radio echo-delay times, and also for the delineation of the wave-form of naturally occurring radio transients.

Using such radio and electronic techniques, the wave-forms of atmospherics, originating in lightning flashes, have been studied in some detail, and instantaneous methods have been developed for finding thunderstorm positions at a distance. Similarly, the use of centimetric wave radar echoes has led to methods of estimating the extent of rainfall areas.

During the War it was discovered that coastal radar stations sometimes received echoes from a ship which had passed well beyond the horizon. The detailed examination of this connexion between radio and the weather has led to the discovery that the lowest layers of the atmosphere may sometimes bend radio wave tracks with a curvature exceeding that of the earth. Such abnormal refraction is associated with temperature inversions and marked water-vapour lapse-rates.

The use of radio-wave exploration for investigating the electrical state of the upper atmosphere has been the subject of continuous experiment in Britain since 1925. It has been found that the ionosphere is subject to a marked solar control, there being a general waxing and waning of the ionization densities in sympathy with the trend of the sunspot cycle. Transient radio echoes have also been noted from the levels of the lower ionosphere, and these have been traced to reflexions from meteor trails.

Finally, the use of sensitive short-wave receivers has disclosed the terrestrial reception of radio noise from both the sun and the stars. Sunspots are found to be powerful emitters of 5-metre waves, the emission being specially enhanced at times of visual solar flares. A continuous radio noise has also been identified as originating in the Milky Way. It is not yet known whether such galactic radio noise originates in interstellar space or in sunspot regions on the stars themselves.

SCIENCE IN THE COLONIES

AFTER reviewing some of the historical examples of the application of research to Colonial problems, Dr. J. L. Simonsen, president of Section B (Chemistry), emphasizes that only with the help of men of science could many of these be solved. While agriculture must continue to be a main industry of the Colonies, its maximum development will require research of a high order. The Colonies can, however, no longer be regarded solely as prime producers, and the introduction of other industries deriving their raw materials from agriculture will be essential. In 1942 the Colonial Products Research Council was formed to review the field of Colonial raw materials, and by research methods ascertain how fuller use could be made of them.

Large-scale industry based on plant products must look to the most abundant of these, namely, the carbohydrates, starch and sugar, as its raw materials. Starch already finds an extended application in industry, and the methods devised at Birmingham for the separation of its two constituents, amylose and amylopectin, have now rendered these products readily accessible. A detailed survey of the little-known starches of tropical Colonial countries is urgently needed. Although sucrose is the organic chemical produced on the largest scale, it has been little used as an industrial raw material apart from fermentation processes. The sucrose molecule is complex, and rapid progress of research into the production of substances of increased industrial value which is now being carried out in Great Britain and the United States cannot be expected, although some of these have been shown to have useful antifreeze, plastic and chemotherapeutic properties.

Recognition of the importance of microbiology has resulted in the decision of the Colonial Products Research Council to open a Microbiological Research Institute in Trinidad. Among the problems it is hoped to attack are those associated with soil fertility and the control of the Panama disease of bananas.

Synthetic organic chemistry has replaced many drugs previously obtained from plants; but this does not, however, diminish the need for a study by modern technique of the constituents of plants with which medicinal properties have been associated. Furthermore, it has been shown that the botanist can no longer disregard the nature of the chemical constituents in his classification of plants.

The value of improved methods of agriculture and the control of soil erosion will be neutralized if steps are not taken to prevent the large losses of the world's food supply incurred through pest infestation. If the new synthetic insecticides, D.D.T. and 'Gammexane', can be shown to be used with safety on foodstuffs, a weapon will be available which should largely eliminate this destruction by insect attack.

Of even greater importance is the control of two of the foremost insect enemies of man and animals, the mosquito and the tsetse fly. Experience with the new insecticide sprays against the mosquito indicates that the problem is not insoluble, and if by a co-ordinated attack on malaria in conjunction with the use of prophylactics, such as paludrine, meets with success, science will have made an outstanding contribution to Colonial prosperity. The control of tsetse, the transmitter of trypanosomiasis, presents a problem of far greater difficulty. The fly can be killed if brought into contact with insecticides, but it is not yet known how best this can be done. Possibly the use of smoke or smoke bombs from aircraft may be a solution; but the problem must be vigorously attacked on a scale commensurate with its magnitude.

GEOLOGY IN THE DEVELOPMENT OF THE COALFIELDS

IN conformity with the general theme of 'swords into ploughshares', the presidential address to Section C (Geology) by Dr. Murray Macgregor deals with the place of geology in the development of the coalfields. The transference of the coal mines of Britain from private to public ownership has created an entirely new set of conditions, bringing with them their own complexities and hazards and demanding vigilant and unsparing service from all concerned. The unified industry will certainly require the best scientific and technical assistance that the country can give. Scientific research applied to the numerous problems that arise in connexion with the exploitation and utilization of the coal resources of Great Britain must be more directive and more closely integrated than in the past. There are the problems connected with occurrence, distribution, structure and correlation; with vertical and lateral variations in the number and thickness of seams, in the lithology, and in the fossil content; with the size and direction of faults, the amplitude and pitch of folds, the occurrence of suites of contemporaneous igneous rocks and of intrusions, etc. There are the chemical and physico-chemical problems connected with the composition and classification of the coals, and the problems related to their preparation for the market and their economic use.

The fact that the geologist is the first link in this chain of concerted effort is too often overlooked or forgotten, and it must be emphasized that all development schemes, short-term and long-term alike, depend upon a proper and thorough knowledge and appreciation of the relevant geological conditions. In the new era opening out, the unified coal industry, with all its potentialities and its capacity to quicken or retard the *tempo* of our whole national life, must receive all the assistance that geology can provide in planning ahead, in suggestions for economic working, in interpreting structures, in reading doubtful sequences, etc.

The task of the geologist in the coalfields is to correlate and assess all the information already available, to advise as to future developments, and to follow these up much more closely than it has been possible to do in the past. This cannot be achieved by periodic efforts or by a discontinuous service. Research in the coalfields is not a series of separate *ad hoc* pieces of investigation but a continuous service which requires a full-time staff. It is only in this way that geology can be enabled to take its proper place in the economic life of the country. It is only in this way, too, that the gaps in our knowledge of many aspects of Carboniferous geology can be filled, and a more and more broadly based synthesis built up. The coal-mining industry has now become a national trust, and it is as such that it must be regarded by all; the issues are clear-cut and indeed vital, and it is for geologists to see that geology plays its part in the difficult times ahead.

ZOOLOGISTS IN WAR AND PEACE

DR. EDWARD HINDLE, in the opening remarks of his presidential address to Section D (Zoology), mentioned that in view of the exceptional conditions under which they met, he proposed to devote his address to an account of some of the work in which zoologists had been engaged during the past few years. He first referred to war-time activities and gave a brief account of the application of the principles of animal coloration, known as camouflage, and also of some work on anti-fouling. Special attention was devoted to the contributions of zoologists to the maintenance of our food supplies, without which it is very doubtful whether the country could have been adequately fed. An important section of this work was the protection of our food stocks against animal pests, and mention was made of the work of the Bureau of Animal Population at Oxford on rodent control and the development of the Infestation Division of the Ministry of Food. The activities of the latter were dealt with at some length, since it developed as a direct result of war conditions and was staffed mainly by graduates in zoology.

Various attempts were made during the War to increase food supplies. These included extending the use of unmarketable fish which, in the English Channel alone, resulted in the production of about 1½ tons a week of excellent fish-paste from fish that was formerly wasted. The experiments at Loch Sween (Argyll) on the possibility of raising the fertility of a given area of the sea by the addition of nitrates and phosphates were also considered.

Zoologists took a prominent part in some branches of operational research. In particular, they were closely involved in the practical development of radar in connexion with gun-laying devices for anti-aircraft guns, and the development of 'H_2S', an apparatus used for the localization of targets. Eventually this was fitted in various aircraft, and its use resulted in enemy submarines being brought under control during the first half of 1943. Moreover, they did not become a serious menace again until the invention of the 'Schnorkel' in 1945.

Zoologists were found to be particularly well-fitted to cope with the early difficulties of radar, since by their training they become accustomed to handling large numbers of uncontrollable variables.

Some of the peace-time activities of zoologists were then referred to, with special emphasis on the work of entomologists in checking the serious losses in our agricultural products, stored products, and in the prevention of disease. To take only one item, the loss of grain in India, due to rodents, insects and moulds, has been estimated to amount to 12–15 per cent, and a saving of 10 per cent would be sufficient to prevent a famine. In Africa the Colonial Development Scheme, involving the expenditure of some £24,000,000 in the production of ground-nuts, would mean the use of mechanized agriculture on an unprecedented scale in that continent, and would create conditions favourable to the spread of animal pests and disease. Dr. Hindle expressed the hope that the number of professional biologists employed in this project would be commensurate with this expenditure.

The subject of taxonomy was then discussed, and the increasing difficulty of getting accurate identifications of species. An Empire Biological Service, somewhat analogous to the Fish and Wild Life Service in the United States, was suggested, as this might offer the possibility of establishing a pool of taxonomic specialists who could be attached not only to national and provincial museums in Britain, but also to corresponding institutions in the British Empire. Ultimately, this might be extended on an international basis. Finally, Dr. Hindle stressed the educational value of an academic training in zoology, which was out of all proportion to its economic possibilities; and appealed for a return to a less mechanistic training of the younger generation.

GEOGRAPHY IN WAR AND PEACE

IN her presidential address to Section E (Geography), Prof. E. G. R. Taylor points out that, while everyone admits that 'circumstances of place', that is, geography, are relevant to human history and human affairs, it remains true that geographical circumstances are normally regarded as 'accidents'; and as being, moreover, of so obvious a character that it needs no trained geographer to point them out, much less being such as to deserve analysis in detail. This over-simplified idea of geography, which can be exemplified in the writings of historians, economists, military commentators and others, is responsible for the fact that the subject receives no mention in the schemes for revised university curricula aimed at the provision of a more balanced general education embracing both science and the humanities. Nor is it included in plans for the advancement and endowment of the social sciences. The pure scientist, too, rejects geography since (except in certain limited aspects) it is not susceptible of study by the method of controlled experiment. Yet departments of geography are over-full, and chairs in geography multiply faster than they can be effectively filled. Ordinary people are recognizing that the regional differentiation of the world's surface (although they would not thus define it) lies behind some of our most crucial problems, and is at the root (for example) of the effective reduction of the number of Great Powers to two.

The causes and consequences of regional differentiation can only be understood in relation to the globe viewed as an organic whole. The concept of 'global thinking' goes back among geographers to the late eighteenth century traveller von Humboldt. As thus envisaged, geography shares with sociology the methodological difficulties arising from the impossibility of isolating 'pure' problems, with the consequent need to call upon a number of diverse skills and specialisms. The present climate of thought is, however, unfavourable to group research (employing specialists from different fields) and even to team research (employing specialists within the same field), and successful examples of such work are few. Nevertheless archæologists, historians, economists, sociologists and physical planners have recently shown an increasing disposition to seek the collaboration or advice of geographers, no doubt because, now that a second generation of trained geographers is coming to maturity, the output of work reaching an acceptable standard of scholarship is increasing. Examples of such work with a particular social bearing include analyses of the geographical circumstances of 'problem' areas—the Italo-Jugoslav boundary, Palestine, the march-lands of Russia, the 'special areas' of Britain—studies in micro-climatology, in coastal morphology, in land-utilization, areas of urban circulation and influence, and so on. The value of maps, not merely as a means of exposition, but also as a tool of research, is also increasingly appreciated.

A world war has for the second time emphasized the need for 'terrain' geography and exposed the gaps in geographical knowledge. New methods of air photography—stereoscopic survey, colour and infra-red photography—are capable of supplying data by which those gaps could be rapidly filled. The interpretation of such data occupied many geographers during the Second World War. Beach reconnaissance, involving a land, sea and air complex, as a preliminary to military landings, called for novel methods of research, and led to new knowledge of shore-line processes and coastal morphology. The use of rockets and unpiloted aeroplanes lends a new importance to exact knowledge of the shape and dimensions of the geoid. The need for popular education in world geography lays upon geographers the duty of designing maps and globes which give a world picture appropriate to an 'air age'.

PROGRESS IN MODERN ENGINEERING

Civil engineering aspects of progress in modern engineering is the principal topic of the presidential address to Section G (Engineering) by Sir William Halcrow. An analysis of engineering evolution involves consideration of mental conditioning in the past as well as of achievement. Society as a whole did not become mechanically minded until after the First World War, and the progress was slow. American influence is considerable, and we must understand the conditions which have led to their lavish use of machines and materials. Reference to the progress of prime movers, of constructional materials, and of some recent developments in technique follows.

The steam engine has been highly developed for many years; but the steam railways require considerable improvements to cater for modern traffic intensities. The great operational inflexibility of the system can only be relaxed by changes in track layout, signalling systems and dead weight of stock.

Steam turbines are our main prime mover for the generation of electricity. Fuel ancillaries are inherently heavy and bulky, however, and the gas turbine, which will soon be in economical operation in aircraft, may challenge the steam turbine on these grounds. At present, however, its life is too short for purely industrial purposes.

The water turbine has been highly developed for some considerable time. Intensive hydro-electric development is taking place in the Highlands of Scotland; but the great Severn Barrage tidal scheme still awaits official approval. With 800,000 kW. installed capacity, it could produce some 2,300 million units of electricity per annum at 0·2*d.* per unit and save one million tons of coal a year.

Our mechanical civilization did not attain a high rate of development until the latter half of the nineteenth century, when iron and steel could be produced in large quantities. The present century has seen the great development of alloy steels, and we may be approaching the end of the age of simple mild steel. The use of light alloys has greatly increased, and it is not generally realized that aluminium production depends entirely on large amounts of cheap hydro-electric power.

Modern cement dates from about 1850; and although its chemistry is still not fully understood, high grades are available in large quantities. A recent advance is the production of low-heat cement. The use of reinforced concrete is widespread, and latterly the technique of pre-stressing has resulted in considerable savings in materials in some cases.

Earthwork has only been scientifically treated since the early 1920's, when Dr. Terzaghi began to publish his penetrating analyses. Some problems still await solution, but we understand their limits and tendencies. Tunnelling is highly mechanized at present and rapid progress is possible. In soft ground, by use of a shield, a 12-ft. Tube railway tunnel in London clay can be advanced by as much as 160 ft. a week.

Prefabrication was used on a large scale for marine works during the War; for example, in the well-known invasion harbours and the lesser-known permanent military ports in some of the Scottish sea lochs.

We have had to develop analysis by experimental methods to a considerable pitch. Electrical resistance strain gauges and photo-elastic methods are useful. In aircraft the piercing of the sonic barrier depends greatly on model and wind-tunnel research. In hydrodynamics, models are most useful for determining hull forms, wave action, silting and erosion in harbours, spillways of dams and similar problems.

ANTHROPOLOGICAL APPROACH IN SOCIAL SCIENCE

In his presidential address to Section H (Anthropology), Prof. C. Daryll Forde discusses the anthropological approach to the social sciences. The social sciences are often regarded as comprising all scholarly studies contributing to the portrayal of social conditions, including historical or descriptive accounts and those directed towards the solution of practical social problems. But more strictly considered, science seeks to establish valid generalizations concerning the properties of a range of natural phenomena, and its precision and explanatory value depend on the accuracy with which these properties are determined and the relations between them established. In this sense, social science must be concerned with the investigation of the nature and conditions of social relations, and should seek valid generalizations concerning variation in the social life of the human species. Interpretations of particular societies past or present, and predictions as to particular social developments in the future, depend for their penetration and reliability on achievement in this more strictly scientific field. This dependence of advance in descriptive and practical studies on the development and application of theory is generally recognized in the field of economics, but has been less readily appreciated by students of social history, politics and ethnology.

Anthropology, traditionally concerned with the study of savage or pre-literate peoples, has developed in response to historical and practical, as well as scientific, interests. But interest in the organisation of these small-scale societies has been considerably stimulated by the hope of obtaining therefrom greater insight into problems of our own civilized societies through a better understanding of universal processes in the social life of man. The comparative study of the whole range of social forms is required for the formulating and testing of fundamental hypotheses concerning the nature of society. As in other scientific fields, advance is often easier with reference to less complicated material provided by small-scale 'primitive' societies. Moreover, the novelty and variety of institutions and social relations in such societies direct attention to problems which tend to be obscured by the particular conditions and conventional definitions current in our own society.

Anthropological studies in the field of culture have traditionally included both descriptive or ethnographic and analytical or sociological studies. It is important to recognize that as in other fields of knowledge, developments in each are interdependent. The scientific study of the social organisation of small-scale societies depends on the analysis of ethnographic data. Ethnography in turn has been rendered intrinsically more adequate and coherent by advances in sociological theory which have posed new questions and provoked new methods.

Thus earlier descriptions of societies organised in wide uni-lineal kin groups, of which only formal and ceremonial features were commonly emphasized, left obscure the processes whereby such groups were formed and maintained, and failed to reveal their role in maintaining social coherence and control among peoples where there is little specialization of activity and status. Analysis of rights and status in ritual, economic and political spheres has led to the discovery of a high degree of segmentation at a series of levels within these and other corporate bodies in other small-scale societies, and has revealed opposed tendencies to solidarity and fission within such groups as part of the adaptive character of social structure in relation to ecological conditions.

The study of corporate activity and leadership in small-scale societies shows that processes which in more complex societies are expressed in specialized religious, economic and political institutions are not absent among the former, but operate through less differentiated, multifunctional organisations. The categories of economics, religion, law and government are found to have wider reference and more variable inter-relations than is commonly recognized from the study of Western societies.

From the internal analysis of particular societies, and comparative studies, the range of conditions in which specialized institutions emerge are being more closely determined. Spencer's hypothesis of social evolution greatly stimulated the development of social anthropology in the nineteenth century. The comparative study of institutions in relation to the total social structure on one hand, and the ecological foundations of social life on the other, promises to yield a theory of social development more valid than the unverifiable speculations concerning the social conditions of early man into which interest was temporarily diverted in the nineteenth century.

WIDER APPLICATIONS OF TEACHING OF PHYSIOLOGY

THE main feature of Prof. Winifred Cullis's address to Section I (Physiology) is a plea for the training of more physiologists and a wider use of their services. Physiology, if it is to take its proper place in education, has a dual function to perform. Its importance in the teaching of medical students is well recognized; but there is too little appreciation of its other aspect as a science which, apart from its medical bearing, is important for the general health of the community. A plea for a wider recognition of this aspect was chosen for the address, not only because Prof. Cullis's war-time experience broke her contact with the more academic side of physiology, but also because in her opinion it is one insufficiently recognized and one in which she is able to draw upon personal experience.

The community owes much to physiology and is interested in hearing of this debt. The newer knowledge of nutrition, with which will always be associated the name of Sir Frederick Gowland Hopkins, has shown its use in dealing with the restrictions imposed by war-time conditions. The story of insulin, itself of great interest, has a special value in these days of popular writings, in giving some idea of the time that may elapse between the making of a discovery and its safe and general application. The decision of the men of Smithfield not to increase the price of pancreatic material, after hearing what this material could mean in giving to diabetic patients the chance of an active life, is a dramatic instance of the value of knowledge. Possibly, too, a better knowledge of physiological principles might enable the public to evaluate more correctly some of the fantastic claims made in advertisements of certain preparations.

Well-qualified teachers of physiology would be of use in many directions. They are much needed in the general training colleges as well as in those devoted to the training of teachers of domestic science and of physical training. They would be of great value in schools in the upper forms, where they could build upon the foundations often so well laid in the junior forms by good biology teaching. In these institutions and in industrial establishments they could be of use in collecting the normal physiological data now recognized as necessary in the departments of social medicine. Social science workers would be helped by such instruction, and in extra-mural university classes and in adult education such teachers could play an important part.

To provide these teachers it will be necessary for the universities to increase the number of students taking honours courses in physiology, but who are not going on to medicine. It will also be necessary for the various educational institutions to realize the value of having on their staffs teachers so trained.

In schools, broadcasting and films can be useful aids, though they in no way lessen the responsibility of the class-room teacher, from whom the main inspiration must always come. In preparing such aids it is necessary to have co-operation between three sets of experts, the class-room teacher and the experts in the subject and in the medium to be used. It is necessary, too, for teachers to have training in the of such use aids.

It is Prof. Cullis's firm conviction that this wider teaching of physiology would result in a better understanding of various problems intimately associated with healthy living, so leading to a higher and better standard of health for the individual.

MAN'S ADAPTABILITY

THE question of the adaptability of man was the theme of Dr. S. J. F. Philpott's address before Section J (Psychology). Many of the problems psychologists have handled during the War and that will face them during the peace have had to do with man's adaptability. Can a bank clerk be changed, almost overnight, into a tank gunner ? Can he be changed back by a stroke of the pen ?

If the doctrine of round pegs in round holes were strictly true such transformations would be difficult, if not impossible. In practice, they can take place with surprising ease, especially if the will to act is present. There are limits. Broadly speaking, men are only adaptable within the limits of their all-round ability; but granted the will and the ability, man can play many parts.

In asking just how an individual is equipped and just how he can adapt himself, we must realize that he works as a whole. When in the workshop planing or sawing a piece of wood, it is my body as a whole that I use, throwing it now into the attitude appropriate to the use of a plane, now into the attitude appropriate to the use of a hand saw. I do not use a planing organ or a sawing organ.

In similar fashion, I am now in the mental attitude appropriate to making an abstract. In a moment I may be in the frame of mind appropriate to making some calculations, or writing a letter, and so on. It is my mind as a whole that I use in each of these operations. I do not use an abstracting organ or a calculating organ.

The problem of education into a given culture is that of giving the individual an enormous number of such attitudes, skills or techniques, ranging from the simplest of everyday actions like opening doors up to the highest expression of the arts and sciences. We only begin to realize the significance of the complex of skills thus built up when we learn about 'wolf children' realizing how much they have lost. Yet no matter how complex the result of all this training, it still remains that all activities can be traced to the functioning of the one general-purposes body-mind instrument.

The problem of drill arises whether in peace or war. It is that of making these various techniques automatic. One cannot enjoy riding a bicycle until all movements of hands and feet and body take place well below the conscious level. No man can be master of his craft until he has made himself a slave to the minor habits involved, the fingering of his instrument or the handling of his tools.

Before advising training, we often to-day apply tests of potentiality. The naïve view is that we ought to be able to devise tests to distinguish between those born to be tank gunners and those born to be tank drivers. In fact, a one-time carpenter can often succeed at either of the other two occupations. Granted that at the moment he knows nothing about either of them, will tests for potential drivers or potential gunners pick him out ? If so, will it not be a case of a test for drivers picking out a potential gunner ? Or so far as that goes, will it not have picked out an actual carpenter ? Put briefly, although it is easy to devise tests of all-round ability (trainability or adaptability) it is quite another matter to discover tests that shall assess potentiality in respect of some one occupation and it alone. There is wide overlap. The bearing of this on problems of peace, such as that of advising children into the best form of education, is obvious.

THE HISTORY OF PLANT FORM

ALTHOUGH in recent years botanists have been mainly interested in the study of growing plants, many of their generalizations are based on a belief that evolution has taken place in the plant world. But since very little historical evidence of the evolution of the flowering plants has been forthcoming, this belief has become a dogma, maintained in spite of the absence of proof. This unsatisfactory position, said Dr. H. Hamshaw Thomas, in his presidential address to Section K (Botany), warrants a survey of our present knowledge of the fossil record.

Past failure to find any clues to the early history of the flowering plants may be due to a deductive examination of the evidence. The logical basis of evolutionary study is different from that of pure or typological morphology, but it has been assumed that the *Urform* of the pure morphologist represents the primitive type of flowering plant. Consequently we may have been searching for structures which have never existed. The actual record of changes in plant form through the ages suggests the evolution of the angiosperms through types very different from those imagined.

The geological record becomes clearer if we compare the plant forms from successive *terrestrial* periods, dividing the geological time-scale in a manner complementary to the normal classification of strata, the groups of which represent periods of marine sedimentation. Owing to the rare conditions under which plants are preserved as fossils, we can never hope to trace real phylogenies, but we can obtain evidence of the ways in which structures have changed in the past 400 million years.

The remains of the Upper Silurian–Lower Devonian land plants show forms widely different from the plants of to-day. Types with smooth forking axes predominated; they had little differentiation into stems, roots and leaves. During the Middle Devonian period there were leaves of several types which seem to be derived from specialized photosynthetic branches. A variety of large, much divided fronds appears in the Upper Devonian–Lower Carboniferous rocks; their ultimate segments were usually small or narrow. Several of them belonged to seed-bearing plants—the pteridosperms. In Upper Carboniferous–Lower Permian times this group had more compact fronds, with larger, partly concrescent pinnules; reticulate venation appeared in some genera. Among these, *Gigantopteris* approaches the type of leaf now characteristic of dicotyledons. Petrified stems with a wide range of structure have been found; some of them suggest an approach to angiospermous structure.

The sequence of reproductive structures forms a coherent series which should be studied without reference to morphological preconceptions. Most of the earlier types had their sporangia on the ends of fertile branches, often in groups. This habit continued through Upper Palæozoic times. Kidston described six different forms of pteridospermous pollen-bearing structures from the Lower Carboniferous, with terminal groups of radially arranged sporangia, and Halle has investigated a number of similar structures from the Upper Carboniferous. All are constructed on the same general plan, which is also seen in the male flowers of many unisexual angiosperms to-day. These structures, as well as the cupulate seeds, generally grew on special branch systems. Halle's suggestion is recalled, that in one line of pteridosperm evolution the plant body was differentiated into a vegetative and a reproductive region, the spore-producing members congregating to form some kind of inflorescence or flower borne directly on branches of the stem and not on leaves. The Triassic pteridosperms from South Africa had dichasial inflorescences and support this view. Another link between the pteridosperms and the angiosperms is provided by certain rare and undescribed fossils from the Molteno beds of South Africa. These show inflorescences of a dichasial type, bearing small flowers with delicate perianth segments.

The closed ovary of the angiosperms may have been derived from the open cupules of the pteridosperms. The Jurassic *Caytonia* suggests how the closure may have come about, and Prof. Doyle's researches on pollination and fertilization in the conifers are interesting in this connexion.

Traces of flowering plants occur in the Upper Jurassic and increase in number until they form more than 90 per cent of the floras in the Eocene rocks. The widely different types present in Cretaceous beds suggest that the group must have originated in Upper Palæozoic or early Mesozoic times. An investigation of the spore content of freshwater sediments may throw light on this suggestion. A high percentage of the families represented in the Upper Cretaceous–Lower Tertiary floras show primitive characters in their secondary wood; by statistical analysis, Sporne has been able to discover other characters probably possessed by the more primitive dicotyledons.

All these studies are independent of morphological theory, and since plant morphology has developed as a deductive study they suggest that a reconsideration of its concepts are necessary. The War showed the importance of a complete and objective analysis of information as a basis for action. This is a principle applicable both to the problems which have been here considered, and to all the affairs of national life.

EVOLUTION OF SECONDARY EDUCATION

In her presidential address to Section L (Education), Miss Lynda Grier discusses "The Evolution of Secondary Education in Britain". The most notable features in the evolution of secondary education in Britain have been, she said, the growth and constant power of the classical tradition, and its decay; the growth of democracy, including the growth of the woman's movement; the coming of science with a new conception of humanism in education, and the interest in technical education.

The dominance of classics in education in the first instance was due to the fact that they were useful and paved the way to office in Church and State, that they were necessary to lawyers and diplomatists, won favour at court, and were, in brief, the main requisite for any who wished to enter the learned professions. Conservatism kept classical teaching powerful when the direct usefulness of the classics had ceased, and brought about a decline in the number of grammar schools, and in the numbers at the universities, until the latter began to take note of the new learning, and it was slowly recognized that education should have some connexion with the world in which men and women had to live. This recognition was due to the growth of democracy and the increasing need of the sciences for the contribution of learned thought and training. As these things came to the fore, secondary education began slowly to take its rightful place in men's minds as something that should be offered to all children.

Early democratic ideas in education in England, unlike those of Commenius, were selective and concerned with the provision of ladders for the poor and able, which would set them side by side with the rich, or even, as some of the most democratic of early English thinkers suggested, above the rich, if the rich were not worthy of the education offered. Hence the English system was profuse in scholarship provision, generously but definitely selective. Interest in the higher education of women suffered an even greater decline than did that for men, until the gradual emergence of a true democracy.

Mathematics and science were not neglected entirely, for indeed much fine work was done in both. But it was carried on outside the universities and grammar schools; and schools of a different type were set up for their teaching, or else, as suggested by Locke, they were taught by private tutors, until at last the ancient universities began to recognize their importance. Technical education, which should long since have come into an important place in education, given the decay of apprenticeship and the competition of other countries, has only recently established its claims in the provision of secondary education.

The general neglect by the State of secondary education in Britain allowed for great variety in it, since what was done was in the hands of private bodies and individuals with widely different points of view. The recent Education Act and all the interpretations given to it by the Ministry of Education recognize the value of that variety. In achieving for the first time a complete system of education, with secondary education for all, it is recognized that unity is incompatible with uniformity, and that the greater the variety the more perfect can be the result.

SOILS AND HEALTH

THE effect of soil conditions on plant and animal health forms the topic of Dr. W. G. Ogg's presidential address to Section M (Agriculture). Great advances have been made in this subject during the past quarter of a century. One of the most interesting discoveries is the part played by what are termed the trace elements from the fact that traces only are normally required. Some of these appear to affect plants only; others both plants and animals; and yet others, animals only. Deficiencies or excesses of these substances have been shown to be responsible for a wide range of plant and animal diseases and cause large annual losses to the agricultural industry. Probably the sub-clinical cases are far more numerous than those with obvious symptoms of disease, and are responsible for even greater losses. We do not know very much about the way in which the trace elements act, but possibly they are catalysts.

Although these trace-element diseases are spectacular and highly important, the major plant foods have a much greater influence on the food supplies and health of the community, and deficiencies of these are much more widespread.

It is obviously of very great importance to agriculture to have as much information as possible about the natural distribution and availability of both major plant foods and trace elements. Much of our knowledge on this subject is due to the geochemical studies of the late V. M. Goldschmidt. He developed improved methods of quantitative spectrography which have been of great value in obtaining the necessary analytical data, and his work on crystal chemistry has thrown much fresh light on the distribution of the trace elements in the earth's crust.

The introduction of fertilizers about a century ago has led to an enormous increase in food production throughout the world. It is not claimed that they have supplanted organic manures. Both have their uses and they should be regarded as complementary. Apart from other considerations, fertilizers are needed if the world's food supply is to be maintained because of the shortage of organic manures.

Violent attacks by some of the enthusiasts for organic manures have been made on the use of fertilizers. It is claimed that they poison the soil and are detrimental to the health of plants, animals and human beings. There is no good evidence in support of these assertions. Far from doing harm, fertilizers, properly used, build up soil fertility. In fact, by enabling larger crops to be grown, they increase the amount of material which can be converted into farmyard manure, and the greater amount of roots and other crop residues also increases the organic matter in the soil. For the same reason they are beneficial rather than detrimental to the soil's population of earthworms and micro-organisms. Nor is there sound evidence in support of the assertion that fertilizers increase the liability of crops to insect, fungus or virus attack, or that they have a detrimental effect on the composition and quality of agricultural produce.

Probably more can be done for the improvement of health in the world to-day by providing ample supplies of food than in any other way, and the propagation of unfounded beliefs about the harmful effects of fertilizers is detrimental to the interests of the whole community.

LOCAL SCIENTIFIC SOCIETIES

AS in many other fields, there is a tendency to take stock, and there has been a suggestion, both expressed and implied, that the day of the local society is past. The Council of the British Association has had the matter under consideration and has circularized its corresponding and affiliated societies asking for detailed information on certain points and for suggestions. The replies have been collated, and the president of the Conference of Delegates of Corresponding Societies, Dr. J. Ramsbottom, made them the basis of his address with the intention of promoting discussion.

Local societies had their origin for the same purposes as the so-called learned societies and even as the old universities—the dissemination or communication of knowledge and the furthering of research. Gresham College, 1596, with its endowed lectures, and the foundation of the Royal Society in 1660, show how in the sixteenth and seventeenth centuries these objects were met. With the advance in learning in the eighteenth century and the realization of the benefit of mutual exchange of ideas, many literary and social clubs met in London coffee-houses and taverns, and larger literary and philosophic societies were founded in different large provincial towns—Edinburgh 1731, Manchester 1781, Newcastle 1793, and so on. Specialized societies began to make their appearance with headquarters in London: the Linnean Society 1788, the Geological Society 1807, Zoological Society 1826 and Entomological Society 1833.

The natural history society may be considered a product of the Victorian era. It was essentially an association of people interested in nature study at a period when systematic botany and zoology were generally regarded as the main part of these subjects. Many of our local Floras and Faunas were due to their activities, and much of real value was published on other branches of biology.

At the present time, most local societies carry on much in the way which was so profitable up to fifty years ago. Since then there has been a crop of societies and clubs dealing with special branches of biology; but the *omnium gatherum* local natural history societies continue, though many cannot be said to flourish. Some, under the stimulus of one or more members, have tended to specialize, but undue specialization defeats its own ends; sections acting as local branches of the larger societies dealing with these subjects would be more profitable. The federation of local societies into regional unions, beginning with the Yorkshire Naturalists' Union, 1877, has proved advantageous and stimulating; but there is need for some collaboration between the unions themselves.

Most natural history societies lament their small membership, particularly the absence of young members. Their enrolment is a task of national importance, for the country will need an increasing number of trained biologists, and it is beyond question that field work is the most profitable method of approaching many fundamental problems as well as inspiring a true interest in biology.

The compilation of records has always been carried on by local societies, and with the possibility of the increase in the number of nature reserves there is opportunity for detailed studies on a broad ecological or biological basis. Indeed, the local natural-history societies might play a large part in protecting these areas and in noting others that are worthy of local or national preservation.

NEWS and VIEWS

Physiology at University College, Dundee: Prof. G. H. Bell

Dr. George Howard Bell, who has been appointed to the chair of physiology in University College, Dundee, is a graduate of the University of Glasgow, where he had a distinguished career in both the Faculty of Science and the Faculty of Medicine, gaining the M.B. degree with honours in 1930 and, later, the higher degree of M.D., also with honours. For the thesis which he presented for the latter degree he was awarded a Bellahouston Gold Medal. After graduation, Dr. Bell spent a period in clinical appointments before entering upon an academic career in physiology, and he has always maintained a close interest in clinical problems. He gave a considerable amount of voluntary hospital service during the War. A year ago he was elected a fellow of the Royal Faculty of Physicians and Surgeons of Glasgow. Prof. Bell's career as a physiologist began with his appointment as an assistant in the Glasgow University Institute of Physiology. This assistantship was followed by a lectureship at the University of Bristol, after which he returned to Glasgow as senior lecturer in physiology. His research interests have been concerned in the main with problems in the physiology of parturition and of reproduction in general; with the significance of capillary fragility tests; and, most recently, with the effect of various factors on the physical strength of bone. Many of these studies are notable for, and indeed have depended for their success upon, the development of new techniques and on the design and construction of novel apparatus; and quite apart from strictly physiological research, Dr. Bell has issued many valuable papers on new and improved methods and apparatus, and on the application of nomograms to physiological and clinical calculations. His practical text-book on experimental physiology has gained acceptance not only in Glasgow but also in several other medical schools.

Physical Chemistry at Durham: Prof. W. F. K. Wynne-Jones

Prof. W. F. K. Wynne-Jones, professor of chemistry at University College, Dundee, University of St. Andrews, has been appointed to the chair of physical chemistry at King's College, Newcastle-upon-Tyne, University of Durham, in succession to Prof. H. L. Riley (see *Nature*, Dec. 14, 1946, p. 867). Prof. Wynne-Jones is a D.Sc. of the University of Wales, having begun his academic career at University College, Aberystwyth; later he went to Oxford. He continued his chemical studies with Brönsted at Copenhagen, and spent some time with H. S. Taylor at Princeton University as a Leverhulme scholar. After having held appointments in the Universities of Bristol and Reading, he went, in 1938, to Dundee. During 1942–44, he took over the duties of head of the Chemistry Department of the Royal Aircraft Establishment, Farnborough; and during the War he also supervised electro-chemical research work, which was carried out at University College, Dundee, for the Ministry of Supply. Prof. Wynne-Jones' main research work has been in the field of chemical kinetics. He has worked on acid-base catalytic reactions in solution, and on electrolytic dissociation processes. His work also includes studies in the role of solvent in reaction kinetic processes, and on the effect of isotope exchange on reaction-rates, particularly the exchange of deuterium and hydrogen.

American Awards for British Men of Science

Dr. H. Roxbee Cox, director of the National Gas Turbine Establishment and chairman and managing director of Power Jets (Research and Development), Ltd., has been awarded the American Medal of Honour with Silver Palm for "meritorious service to the Government of the United States from September 1941 to September 1945, in connection with the development of turbo-jet and turbine aircraft engines. Dr. Roxbee Cox contributed to a great extent to the successful prosecution of this major war project by establishing and effectively administering an efficient system of technical collaboration between the British and U.S. Governments."

Dr. E. Talbot Paris, principal director of scientific research (defence) in the Ministry of Supply, has been awarded the American Medal of Freedom with Bronze Palm for "meritorious service during the period of action in the field of scientific research development. As a physicist in the Ministry of Supply, he was responsible for the development of radar communications and other electronic equipment required for the ground forces of the British Army. He took an active part in establishing the interchange of scientific information with American laboratories, contributing substantially to the development of highly technical equipment."

Exhibition at the National Gallery

On October 8 the National Gallery is re-opening a suite of six rooms, the first to be completely redecorated since the War. Many of the pictures to be shown in these have been re-framed. Nearly all will be shown without glass; though they will be protected by low barriers of silk cord. Fluorescent lighting is being installed in all the rooms. In one of them the walls will be covered with loose hangings of damask. These are all experiments towards the method of exhibition to be adopted in another suite of rooms, now half derelict, which is to be completely remodelled and air-conditioned. The pictures hung in five of the redecorated rooms will be the seventy which have been cleaned during the last ten years. In order of cleaning, they will begin and end with the two portraits of King Philip IV by Velázquez. In date they will range from the fourteenth to nineteenth centuries. The exhibition will show the cleaned pictures together for the first time, on clean backgrounds. Examined under these conditions, and with the help of a few demonstration pictures, 120 comparative photographs, X-radiographs, etc., and a catalogue giving the relevant facts, it will be possible to assess the correspondence on the subject which has appeared in the Press during recent months.

South African Science

The first issue of the newly established monthly journal, *South African Science* (*Suid-Afrikaanse Wetenskap*), has just been published (Vol. 1, No. 1, August 1947). This is the bulletin of the South African Association for the Advancement of Science and is available free to members, but may be obtained also by non-members (15*s*. a year, including postage, Kelvin House, H/v Marshall and Hollard-straat, Johannesburg). The journal is similar to *Nature* in format and make up. There are two valuable main articles: "Scientific Research in South Africa", by Dr. B. F. J. Schonland, president of the South African Council of Scientific and Industrial Research, and "The World View of the Physicist", by Prof.

H. H. Paine. Letters to the Editor and Notes and News are given reasonable space, and there is a further article, "The Control of Reverberation in Theatres and Concert Halls", by Prof. P. R. Kirby. An account of the Oudtshoorn meeting of the South African Association completes the number. The editor of *South African Science* is Dr. H. B. S. Cooke, of the Department of Geology, University of the Witwatersrand, who is to be congratulated on the first number of a journal which is clearly needed in such a rapidly developing area as South Africa.

The Indian Archives

The Indian Archives, the first number of which, dated January 1947, has just been received, is a welcome addition to periodical literature on documentation and to the specialist journals of India; its high quality is assured by the fact that it is published by the Imperial Record Department at New Delhi on behalf of the Indian Historical Records Commission. Since the establishment of the Imperial Record Department in 1891 and the Records Commission some thirty years later, much has been achieved, as reference to their many publications will show, in the collection and systematic classification, calendaring and indexing of the Government of India's extant records and in the technical work of their proper care and preservation. But much remains to be done. There are still many districts in India with an untold wealth of valuable archives in charge of unqualified keepers, and some Provinces and States without central record offices. India is not the only country that has in the past been indifferent to the value of its historical records. There, as elsewhere, healthy signs exist of an awakening of the public conscience, and the new journal is intended not only to stimulate this but also to serve as a clearing house for scientific knowledge on matters of archival interest and as an advice and information centre for Indian archivists. The editorial board proposes to print important articles on archival subjects from the foreign press as well as original contributions and papers dealing with India's special problems. This first number has a very interesting selection; it is well produced and will be well received by all concerned with archives and their keeping. It is to appear quarterly.

A New Mycological Periodical

The well-known periodical *Annales Mycologici*, beginning in 1903, ended with its forty-second volume. The premises of the publisher were destroyed in an air attack in April 1945, and H. Sydow, the editor and founder of the journal, died in the following year. Dr. F. Petrak, the eminent mycologist of the Vienna Museum, has decided to re-start the journal with the title *Sydowia*. It will retain its international character and will appear twice a year, each number containing 12–15 sheets. The first number is to be published this year and will include some papers by Petrak which were contained in Nos. 3–6 of Vol. 42 of the *Annales*, the whole edition of which was destroyed. Mycologists are invited to send original articles for publication in English, French, German, Italian, Latin or Spanish. The price of each volume will be 40 Swiss francs. The publisher is Ferdinand Berger, Horn, Nied.-Österreich; the editor, Dr. F. Petrak, Botanische Abteilung des Naturhistorischen Museums, Vienna, Austria. British mycologists will wish Dr. Petrak success in his venture.

Chymia

The great interest shown in the United States in the history of science is to find a further expression in the inauguration towards the end of this year of an annual publication on historical chemistry, entitled *Chymia*. It is anticipated that each volume will contain about a dozen articles of some four to five thousand words each, written in various languages and contributed by leading authorities from all over the world. It is appropriate that *Chymia* should be sponsored by the Edgar Fahs Smith Memorial Collection at the University of Pennsylvania, for it was in this University that the first American chair of chemistry was established in 1769, in the Colonial period, and filled by Benjamin Rush, one of Joseph Black's earliest pupils at Edinburgh. The editor-in-chief of *Chymia* is Prof. Tenney L. Davis, with a board of five other American editors and a group of consulting editors of international repute, representing, to date, the United States, Great Britain, France, Switzerland, Sweden, Holland, Germany, the Argentine, Brazil and China. The British contributors to the first volume are Prof. J. R. Partington, Prof. John Read and Dr. F. Sherwood Taylor. The secretary of the editorial board is Miss Eva V. Armstrong, curator of the Edgar Fahs Smith Collection, University of Pennsylvania, Philadelphia. Publication in Britain will be undertaken by the Oxford University Press.

Summer School in Physical Chemistry at Cambridge

Designed to bring industrial research into closer contact with academical research, an eight-day course of lectures and class work was opened in the Department of Physical Chemistry at Cambridge on August 16. The pressure of applications induced the organisers to accommodate 180 rather than the 100 applicants originally contemplated. An unexpectedly high number of representatives came from university colleges, technical colleges and schools. Many officers attended from the research departments of the Ministry of Supply, and some from the Services. The majority were drawn from industrial organisations, headed in by a group of twenty-six from various sections of Imperial Chemical Industries, Ltd. Prof. Norrish's inaugural lecture on the history of chemistry at Cambridge was followed by eighteen lectures given by him and his staff and devoted in equal numbers to molecular structure, its quantal interpretation, its optical investigation and its bearing on pure liquids and solutions; polymerization, oxidations, explosions, photochemical reactions and nuclear chain processes; the mechanism of friction, wear and lubrication, and the induction of chemical change by impact. The course was characterized by a friendly exchange of difficulties between those attending the school and those responsible for it, and by the variety of new experimental techniques available for trial. The final meeting was attended by the Vice-Chancellor and addressed by Mr. A. V. Alexander, Minister of Defence.

Libraries and their Use

Some of the papers read at the week-end conference of the London and Home Counties Branch of the Library Association held at Eastbourne in October 1946, which have now been issued as a separate reprint (Library Association, 68 Holloway Road, London, N.7. 5*s*.), although addressed primarily to the public librarian, are of interest to those in charge of scientific or technical libraries and to those using such libraries for research or for other purposes. This applies particularly to the papers in the symposium on special materials in libraries, to which Dr. E. C. Willatts, of the Ministry of Town and Country Planning, contributes some notes on the cataloguing, classification and handling generally of maps, plans and aerial photographs, and Miss D. Tayler, formerly of the Ministry of Information, on the like treatment of pictorial material. Mrs. L. Moholy surveys the various processes of documentary reproduction, including the photostat process and micro-copying techniques, and urges once more the establishment of central offices of documentary reproduction; while two papers by Miss Marie T. Slocombe and Miss Valentine Britten, both of the British Broadcasting Corporation, dealing with sound recordings and describing the B.B.C.'s Recorded Programmes Library and the formation and administration of a gramophone library, respectively, should interest a more limited number of scientific workers. An excellent paper on "Library Co-operation and Publicity", by C. A. Elliott, of the Bermondsey Public Libraries, makes many sound points which could well be laid to heart by the works librarian or the librarian serving a research organisation in industry or elsewhere. The two-fold responsibility is the same: to provide an adequate service and to make it accessible. As in the public library, there is the task of organising an efficient service to meet known needs, of removing all unnecessary hindrances and barriers between the reader and the source of information, and of making known, continuously and effectively, the existence of the service so that it is fully used.

Beilby Memorial Awards

From the interest derived from the invested capital of the Sir George Beilby Memorial Fund, at intervals to be determined by the administrators, representing the Royal Institute of Chemistry, the Society of Chemical Industry, and the Institute of Metals, awards are made to British investigators in science to mark appreciation of records of distinguished work. Preference is given to investigations relating to the special interests of Sir George Beilby, including problems connected with fuel economy, chemical engineering and metallurgy, and awards are made, not on the result of any competition, but in recognition of continuous work of exceptional merit, bearing evidence of distinct advancement in science and practice. In general, awards are not applicable to workers of established repute, but are granted as an encouragement to younger men who have done original independent work of exceptional merit over a period of years. The administrators of the Fund will therefore be glad to have their attention directed to outstanding work of the nature indicated not later than November 1. All communications should be addressed to the Convenor, Sir George Beilby Memorial Fund, Royal Institute of Chemistry, 30 Russell Square, London, W.C.1.

Information on Solar Activity by Radio

As the central station for international co-operation on solar activity, the Swiss Federal Observatory at Zurich is now giving monthly the daily sunspot (relative) numbers by the short-wave service of the Swiss Broadcasting Corporation according to the following programme:

On the 4th of each month:

	G.M.T.					
(1)	07h.20m.	wave-length	25·39	25·28		for Australia
(2)	15 05		19·60	16·87		,, the Far East
(3)	21 50		19·59			,, South America
(4)	22 30		25·28			,, North America
(5)	23 40		31·46	25·28	19·59	,, South America

On the 5th of each month:

	G.M.T.					
(6)	01h.40m.	wave-length	31·46	25·28	19·59	for North America
(7)	03 05		31·46	25·28	19·59	,, North America

For this year, in October, emission 2 will be on October 3 instead of October 4. Emissions 3 and 5 are in Spanish, the others in English.

The Night Sky in September

New moon occurs on Sept. 14d. 19h. 28m., U.T., and full moon on Sept. 30d. 06h. 41m. The following conjunctions with the moon take place: Sept. 10d. 11h., Mars 3° N.; Sept. 12d. 10h., Saturn 4° S.; Sept. 19d. 10h., Jupiter 0·6° N. Mercury and Venus are badly placed for observation during the month and Venus is in superior conjunction on Sept. 3. Mars, in the constellation of Gemini, is visible in the morning hours, rising a little before 0h. during the greater portion of the month. Jupiter, in the constellation of Libra, can be observed in the early part of the night, setting at 21h., 20h., and 19h. 20m. at the beginning, middle, and end of the month, respectively. Its stellar magnitude varies between − 1·6 and − 1·4 during September. Saturn can be seen in the constellation of Leo in the morning hours, rising at 3h. 05m., 2h. 20m., and 1h. 34m., at the beginning, middle, and end of the month, respectively, and is easily recognized by its yellowish hue. Only one occultation of stars brighter than magnitude 6 takes place: Sept. 28d. 01h. 42·5m., τ Aquar.(*D*), the latitude of Greenwich being assumed and *D* referring to disappearance. The autumnal equinox occurs on Sept. 23d. 21h.

Announcements

The Committee of Privy Council for Medical Research has appointed Prof. N. Hamilton Fairley, professor of tropical medicine in the University of London, and Prof. J. H. Gaddum, professor of materia medica in the University of Edinburgh, to be members of the Medical Research Council as from October 1.

The Paint Research Association will celebrate its twenty-first anniversary on Tuesday, September 23 and following days, and the Paint Research Station, Teddington, will be open to visitors. On September 25 Sir Thomas Merton will give a short address, followed by a lecture by Dr. D. A. Sutton entitled "Is Copal Varnish an Alkyd?"; on the next day Sir Lawrence Bragg will speak, and will be followed by a lecture by Dr. G. Herdan entitled "Paint and Mathematics". Applications to visit the Station should be sent to the Director, Paint Research Station, Waldegrave Road, Teddington, Middlesex.

The twenty-second annual conference of the Association of Special Libraries and Information Bureaux will be held at the London School of Economics during September 20–21. The topics to be discussed include the effect of atomic energy developments on scientific and technical publication (Prof. R. E. Peierls); punched card systems in library work (Dr. J. W. Perry, Dr. W. E. Batten and Dr. G. M. Dyson); and format of periodicals (Dr. V. E. Parke, L. J. F. Brimble and L. G. Patrick). Particulars of the meeting can be obtained from the Secretary of the Association, 52 Bloomsbury Street, London, W.C.1.

Effect of Testicular Hormone on the Formation of Seminal Fructose

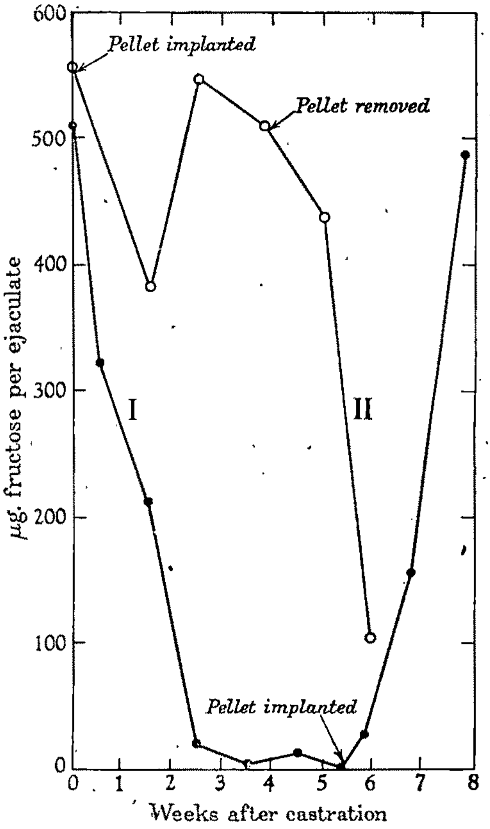
PREVIOUS experiments have established the fact that mammalian semen contains fructose, its concentration varying from a few mgm. per cent in boar to 1,000 mgm. per cent in bull; this sugar serves the spermatozoa as their natural nutrient, and they readily metabolize it[1,2]. At the site of its origin in the testis, and in the epididymis, the semen contains very little fructose but acquires it during its passage through the male generative tract, from the accessory glands of reproduction, mainly the seminal vesicles[3].

In the course of experiments designed to solve the mechanism of fructose formation in the accessory glands, we have now found that the process of fructose generation is linked in a striking manner with the action of the testicular hormone and, furthermore, that characteristic fluctuations in the level of seminal fructose can be evoked in response to testosterone. For the investigation we have used sixteen fully fertile bucks; some of them were castrated, while the others were used as controls. The collection of semen was carried out at weekly intervals by the method of Macirone and Walton[4]. Fructose was determined by the method previously described, using 0·1 ml. samples of semen and 0·05–0·2 gm. samples of the various tissues[3].

EFFECT OF TESTOSTERONE ON FRUCTOSE CONTENT IN ACCESSORY GLANDS

	Gl. vesicularis and seminalis		Prostate	
	Weight mgm.	Fructose mgm. %	Weight mgm.	Fructose mgm. %
Non-castrated buck	780	62	860	79
1 week after castration	860	84	590	18
2 weeks after castration	680	5	410	5
5 weeks after castration	420	3	540	3
8 weeks after castration and simultaneous implantation of testosterone pellet (100 mgm.)	1100	29	1170	71

Within the first two or three weeks following castration, there was a remarkable fall in the fructose content of accessory glands, and usually by the end of the second week the organs were almost completely depleted of fructose. This post-castrate fall in fructose, however, could be prevented by the implantation of pellets of pure testosterone under the skin of the castrated animals (see table). An even clearer picture was obtained through the study of the effect of testosterone on the level of fructose in the semen itself, as illustrated in the accompanying graph. Castration caused a sharp decrease in both the volume of ejaculates as well as in the concentration of fructose in semen, so that the actual quantity of fructose per ejaculate, which normally amounts to some 500 μgm., dropped within three weeks following castration to less than 20 μgm., remaining low until a pellet of testosterone was implanted. In response to testosterone, there was an increase in the volume of ejaculates together with a rise in fructose which soon reached the pre-castration level (Curve 1). In presence of the pellet, a high concentration of fructose could be maintained in the castrated animal for several weeks. However, when the pellet was removed, a significant fall in seminal fructose was registered again (Curve II). From these results we are inclined to conclude that testosterone is the hormone responsible for the formation and maintenance of fructose in semen.



It has long been known that the weight, size, histological appearance and secretory function of certain accessory organs, notably the seminal vesicles and prostate, are strictly dependent on, and closely regulated by, the internal secretion of the testes; and that the typical retrogressive changes which develop in the accessory glands after removal of the testes can be counteracted by injections of the testicular hormone, thus serving as 'indicator tests' for the male hormone. To these biological tests may now be added the highly sensitive 'fructose test' whereby the testicular hormone can be conveniently assayed in castrated animals, simply by examining the fructose content of the semen or of the accessory glands. It may be added that the post-castration fall in the level of fructose and its restoration by testosterone occurs more rapidly and is much more marked than the rather slow and gradually developing gross morphological changes in the accessory glands of reproduction.

This work has been carried out on behalf of the Agricultural Research Council. We are grateful to Dr. J. Hammond, Mr. J. Hammond, jun., Prof. D. Keilin and Dr. A. Walton for placing the experimental animals at our disposal, for help and advice, and to Dr. W. J. Tindall, Organon Laboratories, for a gift of pure testosterone.

Functional Development of Accessory Glands and Spermatogenesis

WHEN fructose was established as the normal nutrient material for spermatozoa and its origin traced to the seminal vesicles[1], it remained to be explained how certain animals, such as the rabbit, secrete fructose in semen in spite of the absence of seminal vesicles. The rabbit, however, has a large complex organ, sometimes referred to as the 'prostate', which has been described hitherto as composed of three glands, 'gl. seminalis', 'gl. vesicularis' and 'prostate proper', each with an independent urethral outlet[2]. However, our recent investigation of the development of the male reproductive system in the rabbit has established that the gl. seminalis develops in conjunction with the gl. vesicularis from the same diverticulum of the Wolffian duct; further, both glands possess a common urethral outlet, and gl. vesicularis as a whole, rather than the gl. seminalis by itself, should be regarded as homologous to the seminal vesicle in other mammals[3]. This, incidentally, explains the presence of fructose in the gl. vesicularis. It should be pointed out, however, that in the rabbit, apart from this gland, fructose also occurs in the ampulla of the vas deferens as well as in the 'prostate proper'. The distribution of fructose in the various parts of the reproductive system of the male rabbit is shown in the accompanying sketch.

	Weight of organ (mgm.)	Fructose in organ (mgm.)	Fructose (mgm./100 gm. tissue)
Epididymis	600	0·03	5
Testis	2900	0·06	2
Ampulla	130	0·03	23
Gl. seminalis	150	0·04	26
Gl. vesicularis	920	0·79	85
Gl. paraprostaticæ	190	0·092	48
Prostate I and II	335	0·368	110
Prostate III	475	0·272	57
Cowper's gland	1000	0·0	0·0

In the course of investigations on the development of the reproductive system in the rabbit, we noticed that fructose appeared in the accessory glands at an early stage when there was as yet no sign of active spermatogenesis. In a four-months-old animal, both the gl. vesicularis and the prostate showed already a fairly high concentration of fructose (21 and 44 mgm. per cent, respectively) in spite of the complete absence of spermatozoa in the testis or the epididymis. When, in the sixth month of life, the spermatozoa finally made their appearance, the accessory glands were filled with secretory fluid containing the normal high level of fructose. Experiments on bull-calves gave similar results, showing that the appearance of fructose in the secretory fluids of the accessory glands precedes the onset of active spermatogenesis.

Thus it appears that the male reproductive organs first accumulate a store of nutrient material, so that when the motile spermatozoa make their appearance in the generative tract, the fructose reserve is available, ready to be utilized. Together with the recent finding that the formation of seminal fructose requires the presence of the testicular hormone[4], our experiments provide additional evidence that the testicular hormone begins to function in the body some time before actual spermatogenesis.

Oxidation of Insulin by Performic Acid

FROM the determination of the terminal residues of insulin, it was suggested that the submolecule of molecular weight 12,000 is made up of four peptide chains bound together by —S—S— linkages[1]. Thus if one could break the —S—S— linkages without affecting any other part of the molecule, it should be possible to split the insulin into its separate polypeptide chains, two of which have terminal glycyl residues and the other two phenylalanyl residues. Toennies and Homiller[2] showed that the only amino-acids that are appreciably oxidized by performic acid are tryptophan, methionine and cystine, the latter reacting with five atoms of oxygen and presumably forming cysteic acid. Since insulin contains no tryptophan or methionine, this seemed a suitable way of splitting the —S—S— linkages.

Using the procedure of Toennies and Homiller, it was found that the oxidation of cystine to cysteic acid is complete in five minutes. With insulin an oxidation-time of 15 minutes was generally used. The oxygen consumption was the theoretical one for the cystine content, and paper chromatography[3] showed no qualitative difference in the amino-acid composition except the replacement of cystine by cysteic acid. There was no destruction of the free amino-groups[1]. The oxidation product was studied in the electrophoresis apparatus of Tiselius. Unfortunately, it was not possible to dialyse the material, due to its low molecular weight (about 3,000), so that the results were not always entirely reproducible. Fig. 1 illustrates a typical experiment, which shows three components and indicates that the mixture is not unduly complex.

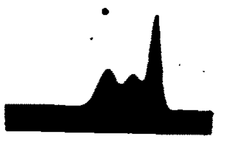

Fig. 1. ELECTROPHORETIC DIAGRAM OF OXIDIZED INSULIN

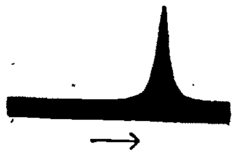

Fig. 2. ELECTROPHORETIC DIAGRAM OF FRACTION *A*

By neutralization at *p*H 6, two fractions of about equal weight can be obtained. The solution (fraction *A*) contains predominantly (80 per cent) glycyl terminal residues, and the precipitate (fraction *B*) predominantly phenylalanyl terminal residues. By further treatment of fraction *A* a product can be obtained which has no phenylalanyl terminal residues and appears to be homogeneous by electrophoresis (Fig. 2). It contains no lysine or arginine. Estimation of the terminal glycyl residues suggested a molecular weight of about 2,500. Fraction *B* has not yet been further purified.

The work is being continued, and a more detailed report will be published later.

Malonate and Plant Respiration

SINCE Quastel and Whetham's discovery in 1925[1], biochemists have come to regard the malonate ion as one of the very few specific enzyme inhibitors—as a competitive inhibitor of succinic dehydrogenase[2]. Malonate has therefore been widely used with animal tissue, in work designed to elucidate the Krebs cycle. Recently it has also been applied to plant tissues, but with discordant results. Machlis[3] showed that malonate inhibited part of the respiration of barley roots; but several other workers have independently stated that malonate does not inhibit and may even stimulate plant respiration[4-7].

In 1938, Turner[8] pointed out that the apparent differential effect of iodoacetate on respiration and fermentation was probably explicable in terms of the different rates of penetration of the drug into the cells, under aerobic and anaerobic conditions. In spite of a general increase in our knowledge of cell permeability, this aspect of work with inhibitors and living tissue is still neglected. It is highly probable that the reported lack of inhibition of plant respiration by malonate is due simply to the use of the malonate ion instead of the malonic acid molecule as a cell penetrant.

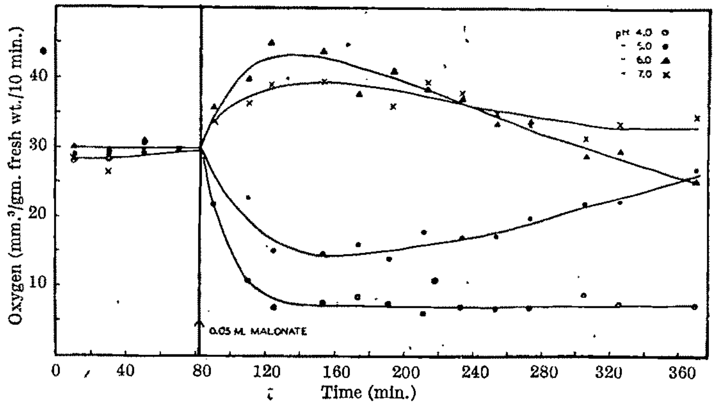

FIG. 1. REACTIONS OF TISSUE RESPIRATION TOWARDS POTASSIUM MALONATE SOLUTIONS OF INCREASING ALKALINITY. UNDISSOCIATED ACID IN SOLUTION: *p*H 4, 98%; *p*H 5, 84%; *p*H 6, 33%; *p*H 7, 5%. CARROT TISSUE, 308 HOURS FROM CUTTING

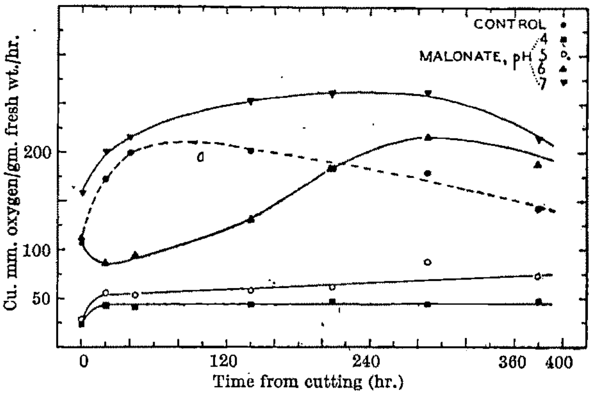

FIG. 2. DRIFT OF RESPIRATORY RESPONSES OF CARROT TISSUE TOWARDS POTASSIUM MALONATE SOLUTIONS, WITH TIME FROM CUTTING. THE VALUES PLOTTED ARE THE MINIMUM (OR MAXIMUM) RATES OF OXYGEN UPTAKE ACHIEVED IN THE SEVERAL EXPERIMENTS

In work with tissue slices of carrot root we have found (Figs. 1 and 2) that potassium malonate (0·05 *M* in distilled water) at *p*H 4·0 causes inhibition of that fraction of the respiration which is inhibited by cyanide[9]. The malonate effect at *p*H 4·0 therefore supports the view of Marsh and Goddard[10] that the cyanide-sensitive respiration in carrot is mediated by the cytochrome-oxidase system, for this is coupled with succinic dehydrogenase.

At *p*H 4, about 98 per cent of undissociated malonic acid is present and might be expected to penetrate cell membranes rapidly. As shown in Fig. 1, very different results are obtained if malonate is applied at *p*H 5, 6 or 7, rather than at *p*H 4. At *p*H 7·0, when only 3 per cent of the undissociated acid is present, the potassium malonate causes a clear stimulation of the oxygen uptake. Because of the associated *R.Q.* effects, we provisionally assign this stimulation to the effect of the potassium ion in bringing about an 'Ulrich' effect, that is, a shift in the balance of the organic acids which leads to an increased respiration-rate[11]. Malonate effects at *p*H between 5·0 and 7·0 (but not at 4·0) vary markedly with the period of time that elapses between the cutting of the slices and the experiment (Fig. 2). For example, at *p*H 6·0 (33 per cent molecule) malonate applied to freshly cut tissue produces a clear-cut but partial inhibition of the cyanide-sensitive respiration. If the tissue is first washed in distilled water for 300 hours, the malonate causes stimulation of the respiration; if the tissue is washed for only about 200 hours, the malonate has no effect whatever upon the rate of oxygen uptake. These curious effects are difficult to explain at present; but at least they emphasize once again the fact that freshly cut tissue slices differ remarkably from long-washed, 'aged' slices in their physiological behaviour[12].

Where the authors who have noted no inhibition of plant respiration by malonate have stated fully their experimental technique, it is usually possible to explain their results in terms of the facts recorded above. Malonic acid appears to enter the cell membrane at an appreciable rate only as the undissociated molecule. As the actual enzyme inhibitor is probably the malonate ion, it is to be presumed that the succinic dehydrogenase of plant cells is not located on the outer cell membrane as was suggested for bacteria by Quastel.

We have extended this work to red-beet tissue, which was stated by Bennet Clark and Bexon[4] to be insensitive to malonate. We find that the effects of malonate on beet-tissue slices are closely similar to those recorded in Figs. 1 and 2 for carrot. There is one interesting difference. Malonic acid at *p*H 4·0 causes inhibition of the cyanide-sensitive respiration[13] of beet tissue, but (for well-washed tissue only) the rate of oxygen uptake later rises again to a value above the normal rate, after which there is once more a sharp decline. Simultaneously, the cells lose and oxidize some of their vacuolar pigment. We explain this additional complexity as due to the loss of cell organisation leading to non-respiratory oxidation of cell contents.

Although *p*H changes *per se* have some effects on respiration-rates, they can be shown not to be responsible for the malonate effects described. For example, succinic acid produces its greatest stimulatory effects at *p*H 4·0. The increased respiration brought about by this and other organic acids is inhibited by malonate at the same *p*H (4·0), both in carrot and beet tissue. However, results in this laboratory make it doubtful whether malonate acts, *in vivo*, only as an inhibitor of succinic dehydrogenase. Our experiments to date indicate that its inhibitory effect is not reversed by high succinic concentration, or even by fumaric acid.

We are indebted to Dr. R. N. Robertson, with whom we have discussed this problem. This work will be published in full elsewhere.

Raphanin, an Antibacterial Principle of the Radish (*Raphanus sativus*)

IN the course of investigation of the watery extracts of different plants by the cylinder plate method on plates seeded with *Staphylococcus* and *Bact. coli*, it was found that the extracts of the seeds of radish (*Raphanus sativus*) gave a very marked zone of inhibition in both cases, whereas the extract of the root and the leaves did not affect the growth of the bacteria. The antibacterial principle of the extract was resistant to heat, and it could even be boiled on a water-bath for 30 minutes without a marked loss of activity. The substance responsible for the activity was isolated from the water extract of the seeds, and a syrupy liquid was obtained of boiling point 135° C. under 0·06 mm. mercury pressure, which could be distilled as a homogeneous substance. The almost colourless, or slightly yellow, distillate proved to be the active antibacterial principle, and has been termed 'raphanin' by us. As it was estimated on the basis of antibacterial tests, 1 kgm. of the seeds contains about 6–8 gm. of this active principle, the yield of the raphanin on isolation being about 3 gm. per kgm. of seeds.

The raphanin is freely soluble in water, ethanol, butanol, butyl acetate, amyl acetate and chloroform. It is moderately soluble in ether, and very slightly soluble in petroleum ether. The products from different batches proved to be identical, and on elementary analysis raphanin was found to have the following percentage composition: C 41·44, H 5·33, N 8·65, S 33·64. Calculated percentage composition for $C_{17}H_{28}N_3O_3S_5$: C 42·48, H 5·45, N 8·74, S 33·35; and for $C_{17}H_{26}N_3O_4S_5$: C 41·11, H 5·28, N 8·58, S 33·03.

The raphanin is neutral and optically active: $[\alpha]_D^{20°}$ in ethanol being − 141°. The solution of the active principle does not give the recognized test as recommended by Jacobs and Hoffman[1] for unsaturated lactones. When the watery solution of raphanin was heated with the salts of heavy metals, for example, silver nitrate, a great bulk of metal sulphide was precipitated, and the antibacterial action was lost. The antibiotic was not inactivated by cystein. The raphanin is stable between *p*H 3 and 8, but above this is readily decomposed. On shaking with 0·1 *N* baryta at room temperature and neutralizing the excess alkali with sulphuric acid, an inactive crystalline substance was obtained on standing the solution in an ice-chest. This inactive substance, sparingly soluble in water and in organic solvents, was recrystallized in ethanol and the recrystallization repeated in water; m.p. 192–193° C. (uncorr.) at decomposition. The inactive substance contains: C 34·65 per cent, H 5·30 per cent, N 6·73 per cent, and S 45·37 per cent. Formula $C_6H_{11}ONS_3$ requires: C 34·45, H 5·30, N 6·69, S 45·95 in per cents.

When tested by the cylinder plate method on plates seeded with different Gram-positive and Gram-negative bacteria, a solution containing 1 mgm. of raphanin per ml. gave a zone of inhibition in mm. as follows: *Staphylococcus aureus*, 18; *Bact. coli*, 16; *Sal. typhi-H*, 19; *Sal. typhi-O*, 24; *Sal. schottmülleri*, 22; *Bact. Shiga-Kruse*, 16; *Pseudomonas aeruginosa*, 19; *Bact. anthracis* (avirulent), 23; *Bact. anthracis* (virulent), 22; *Bact. subtilis* (strain 'Duthie'), 20; *Bact. prodigiosus*, 12.

Raphanin is highly active in preventing the germination of the seeds of different plants. This kind of effect, which was called by Köckemann[2] the blastokolin effect, is shared by different lactones, particularly by coumarine[3]. A 1 : 1,000 solution of the raphanin prevented germination of the seeds of *Festuca pratensis*, *Brassica oleracea*, *Sinapis alba*, *Cucumis sativus*, *Hordeum distichon*, etc. At a concentration of 1 : 10,000 germination was retarded, and the length of the root was markedly reduced by the end of the third day. Raphanin did not, however, significantly influence the germination of the seeds of radish even at a concentration of 1 in 1,000.

The substance proved to be moderately toxic; 10 mgm. doses given intravenously killed mice, whereas after doses of 5 mgm. mice appeared markedly unwell but recovered within a short time. The perfusion of the isolated frog's heart with raphanin at a concentration of 1 in 800 caused slowing of the heart, relaxation of the tone and amplitude. This effect showed itself within five minutes and progressed until the heart stopped. After perfusing with Ringer's solution there was recovery of the amplitude, but the pulse-rate remained depressed. A concentration of 1 : 8,000 of the substance did not affect the contraction of the heart.

The growth of tissue cultures from rabbit testicle[4] was hindered by raphanin even at a considerable dilution. A concentration of 1 : 20,000 of the antibiotic prevented entirely the growth of the explants, and a dilution of 1 : 40,000 caused diminished growth of the fibroblasts, as compared to that of the controls.

We are indebted to Prof. V. Bruckner and Dr. J. Kovács for carrying out the elementary analyses.

Full details of these observations will be published elsewhere.

Thiamine of Milled Raw and Parboiled Rice

IT has long been known that the vitamins of cereals are not evenly distributed throughout the grain but are concentrated mainly in the outer coats and in the germ, which consists of the embryo and attached scutellum.

Analyses of the meals and flours of the miller have been somewhat misleading because some mixing of the products from different parts of the grain takes place within the mills. Dr. J. J. C. Hinton, of the Cereals Research Station at St. Albans, dissected cereal grains, accurately separating the different structures, and determined the vitamin content of each structure. He reported[1] that there was a surprising concentration of thiamine in the scutellum of wheat, and that although it forms on an average only 1·54 per cent of the grain, yet it contains 59 per cent of all the thiamine present in the grain. In a later paper[2] he recorded that the scutellum of rye, maize and barley had similar very high contents of thiamine.

This is an important matter in respect of rice milling, for it is probable that rice is not an exception and that much of the thiamine is concentrated in the scutellum. Rice is either milled raw or it is milled after parboiling. Many analyses have shown that parboiled rice is richer in thiamine than highly milled raw rice, and this agrees with the experience that beriberi is very rare or does not occur where parboiled rice is the staple article of diet.

It has generally been accepted that parboiling distributes the vitamins of the pericarp and germ throughout the whole grain, and therefore milling can remove only a small amount with the bran. Recently, I have examined a large number of grains from several samples of raw milled rice and parboiled rice. The great majority of the grains of raw rice had a concavity marking the site from which the whole germ (scutellum and embryo) had been detached. On the other hand, the grains of parboiled rice did not show the concavity; but the site of the germ was flattened as though only part of the germ had been removed by milling. It appeared as though parboiling had made the scutellum more adherent, so that it had not been detached during milling.

Hinton[2] found that twelve hours soaking of wheat did not cause any movement of the water-soluble thiamine to the rest of the grain. He suggested that the cells of the scutellum are not permeable to water until they have been acted upon by acid chloroform or some other agent. Possibly also the high fat content of scutellum may be a bar to the penetration of water.

Parboiling and also the new conversion process, which is parboiling first under vacuum and then under pressure, toughens the rice so that far fewer grains are broken during milling than in the case of raw rice; this lowering of brittleness would help the retention of the scutellum. Probably parboiling does cause some movement of the vitamins within the grain; but its chief value may be the retention of the scutellum.

Marking Mosquitoes with Fluorescent Compounds and Watching them by Ultra-Violet Light

A TECHNIQUE for marking mosquitoes with fluorescent compounds and watching them by ultra-violet light has been developed, to study the movements of these insects at night without affecting their normal behaviour. The method seems very promising and opens out possibilities for the study of the ecology and bionomics of mosquitoes hitherto not possible.

Zukel[1] used fluorescent compounds to detect marked insects in a large number of specimens, but no attempt was made to develop the technique to observe the insects at night under natural conditions. For this purpose investigations were carried out to ascertain: (*a*) the sensitivity of mosquitoes to shorter wave-lengths, (*b*) whether the insects can take up sufficient dust on their bodies to fluoresce brightly, (*c*) the toxicity of fluorescent compounds to insects, (*d*) whether it would be possible to watch the dusted insects at night by ultra-violet light, and what would be the normal range of visibility.

Mosquitoes, unlike some other insects (honey bees and *Drosophila*), are not sensitive to the ultra-violet radiations of wave-lengths given out by the lamp used (4070–3130 A., 95·5 per cent being concentrated at 3650 A.). Both positive and negative reactions were compared to the behaviour in ordinary light. The species studied were *Anopheles maculipennis* var. *atroparvus*, *Culex molestus* and *Aëdes ægypti*.

Mosquitoes take up sufficient dust to fluoresce brightly, and the dust does not shake off for a number of days. The fluorescent compounds have apparently no toxic effect on these insects as judged by their survival for more than one and a half months after dusting. The dusted insects fluoresce very brightly and can be watched at a distance of about ten feet.

The fluorescent compounds used were anthracene, 'Photophour' and standard 'Mazdalux' powders P_2, P_4 and P_{4xx}, P_5 and P_{5xx}, and P_7, giving bright blue, green, yellow and red fluorescence. The ultra-violet lamp used was a 125-watt 'Mercra' lamp with a concentrating reflector. The dusting procedure is very simple. The mosquitoes are placed in a glass chimney and given a few puffs of the fluorescent dust by means of a hand duster. Aqueous suspensions of fluorescent compounds in spirit gum or slightly soluble dusts in standard cobalt salt solution are not recommended, as the spray accumulates on the wings only and the fluorescence is comparatively poor.

It has not been possible to develop an apparatus capable of working from a 6–12-volt battery; the standard 'Mercra' lamp used in these experiments works on 220 volts A.C.

I should like to thank the British Thomson-Houston Co., Ltd., for the loan of the apparatus, for supplying fluorescent compounds and for other technical assistance.

'Evaporation' of Heavy Nuclei

THE behaviour of atomic nuclei under very high excitation can at present only be studied by examination of the nuclear disintegration 'stars' produced by high-energy cosmic ray particles. Below is given a brief account of results obtained in a preliminary examination of Ilford Nuclear Research emulsions exposed to the cosmic radiation.

Measurements have been made on the energy distribution of particles from the disintegration of fifteen heavy nuclei (silver and bromine), out of a total of some two hundred stars found on 400 sq. cm. of plate area. A star was assumed to be due to a heavy nucleus if the ejected particles carried a total charge of more than eight units, and was only accepted for measurement if at least one long proton track ended in the emulsion, so that the latent image 'fading' could be allowed for in determining track energies from grain counts.

In Fig. 1 the histogram indicates the energy distribution of a total of eighty star proton tracks. Such tracks in $B2$ and $C2$ emulsions become very difficult to detect at energies greater than 100–200 MeV.; hence the stars may well include protons (and mesons) of too high energy to be observed; but at energies less than 100 MeV. the proportion of tracks missed in detailed examination of the stars is believed to be very small.

The process leading to the emission of particles may be visualized as follows. When the incident cosmic ray particle strikes the nuclear surface, its energy is divided in the first instant of time among only a few nucleons. In most cases, the latter will then interact with other nucleons and produce a general 'heating up', until 'thermal' equilibrium is attained. The disintegration process is then analogous to the evaporation of a drop of liquid, and particles are ejected under arbitrary angles, as in Fig. 2. In the case of fairly heavy nuclei, an approximate theoretical treatment of the problem is possible from a thermodynamic point of view, and the energy spectrum of charged particles evaporating from a highly excited nucleus in 'thermal' equilibrium at temperature T is given by[1]

$$P(E)dE = \text{const.}\ \frac{(E - V)}{T^2}\ \exp\left\{\frac{-(E - V)}{T}\right\} dE, \quad (1)$$

where V is the potential barrier height. The value of T drops during the evaporation; also, the temperature depends, though fortunately not very critically, on the excitation energy, which will be different for every star. The average value of E from (1) is

$$\overline{E} = 2T + V, \quad (2)$$

so that it is possible to obtain a mean value of $\overline{T}$ for all stars by using the experimental value of $\overline{E}$. Cutting off the observed spectrum at $E = 40$ MeV. (for reasons apparent below), one finds $\overline{E} = 13$ MeV. The experimental distribution is then reasonably well represented by equation (1), choosing $V = 3$ MeV., so that $\overline{T} = 5$ MeV. (dashed line in Fig. 1). From the proportion of protons at the low-energy end of the histogram, one can conclude that in these pro-

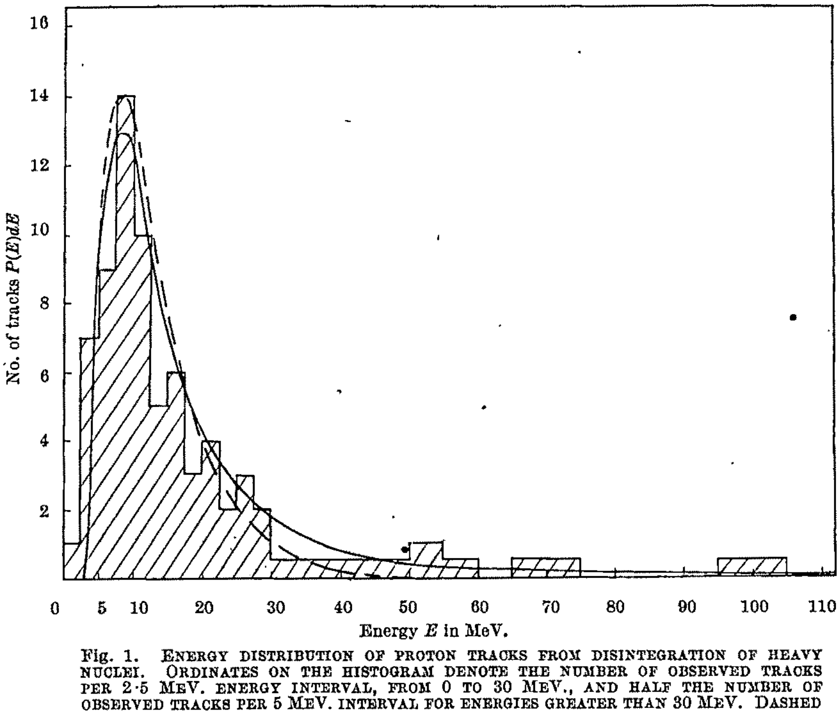

Fig. 1. Energy distribution of proton tracks from disintegration of heavy nuclei. Ordinates on the histogram denote the number of observed tracks per 2·5 MeV. energy interval, from 0 to 30 MeV., and half the number of observed tracks per 5 MeV. interval for energies greater than 30 MeV. Dashed and full curves correspond to equations (1) and (3)

cesses the barrier height is in any case a very ill-defined quantity ($V = 6$ to 7 MeV. from the nuclear radius, as obtained by alpha-decay measurements).

Some 9 per cent of the tracks are due to protons having energies greater than 50 MeV. (for example, track *B* in Fig. 2), whereas according to (1) such tracks should form only 0·2 per cent of the total. It is therefore clear that the high-energy 'tail' of the spectrum is not explicable on the Bohr evaporation hypothesis. At least three of the seven tracks in question have sufficient length in the emulsion to identify them as due to protons, and it seems unlikely that the remainder were produced by slow mesons[2]. According to Heisenberg, these high-energy protons are produced as follows. On being struck by the incident particle, some of the particles on the nuclear surface would be expected to have their velocities directed outwards, and will therefore leave the nucleus immediately with a very high energy (especially if the incident particle strikes the nucleus at a 'glancing angle').

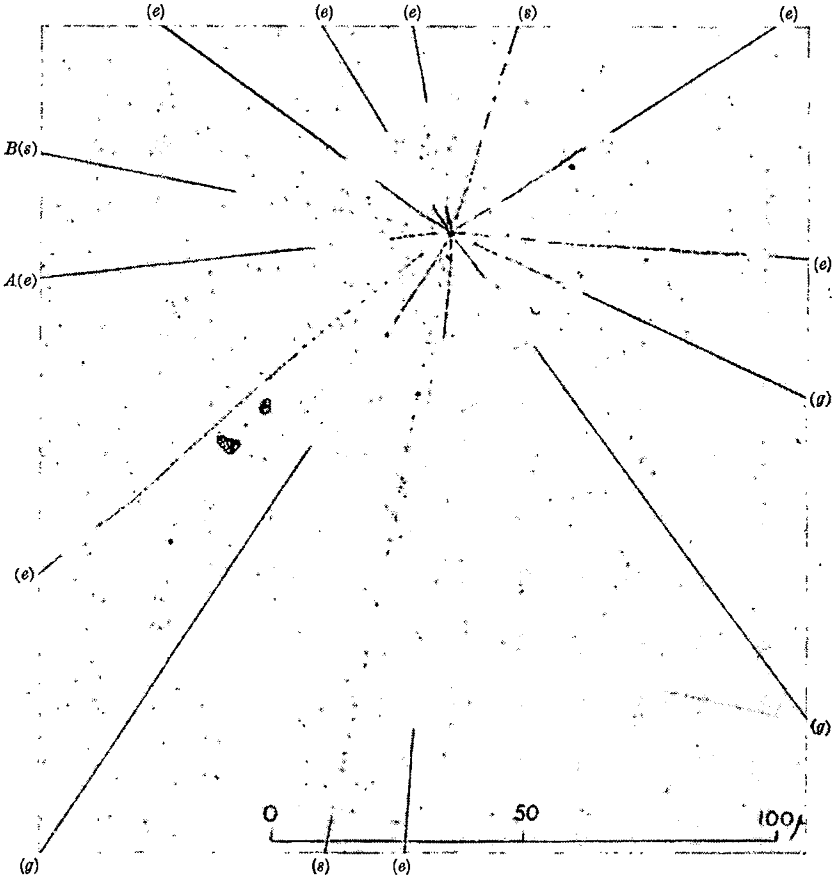

Fig. 2. MOSAIC OF 30 PHOTOMICROGRAPHS OF TYPICAL STAR IN 50 μ *C*2 EMULSION. LEITZ × 75 OBJECTIVE. AT LEAST 16 PROTONS, α-PARTICLES AND HEAVIER PARTICLES (ALL TRACKS NOT SHOWN) ARE EJECTED WITH VARIOUS ENERGIES BETWEEN 70 MEV. (TRACK *B*) AND 0·8 MEV. (TRACK *A*). TRACKS ENDING IN THE EMULSION DENOTED BY *e*, AND THOSE PASSING INTO THE GLASS OR OUT OF THE SURFACE BY *g* AND *s* RESPECTIVELY

It has been found that this high-energy tail of the histogram can, for example, be represented by an expression of type (1), and the spectrum indicated by the full line in Fig. 1 is given by

$$P(E)dE = \left[\frac{(E-V)}{\bar{T}^2} \exp\left\{\frac{-(E-V)}{\bar{T}}\right\} + \frac{1}{4}\,\frac{(E-V)}{\tau^2} \exp\left\{\frac{-(E-V)}{\tau}\right\}\right] dE \quad (3)$$

for the energy-range considered (0–100 MeV.). A value of τ of about $4\bar{T}$ (= 20 MeV.) gives the best fit. 8 per cent of the spectrum then lies at energies greater than 50 MeV. It is, however, difficult to associate τ with temperature, since the latter fundamentally implies an equilibrium state, which is certainly not attained, even though the Heisenberg process may conceivably include ten particles or so.

In addition to protons, about 25 per cent of the star tracks were due to alpha-particles; an accurate measurement of their energy distribution has not yet been possible, since the grain density along alpha-tracks changes only slowly with energy.

The average energy required to eject a proton or neutron from the nucleus is $\bar{E} + E_0$ ($E_0 = 8$ MeV. being the binding energy), so that assuming rather more than one neutron emitted for every proton observed, and including the alpha-particle tracks, the average value of the excitation energy $U \sim 300$ MeV.

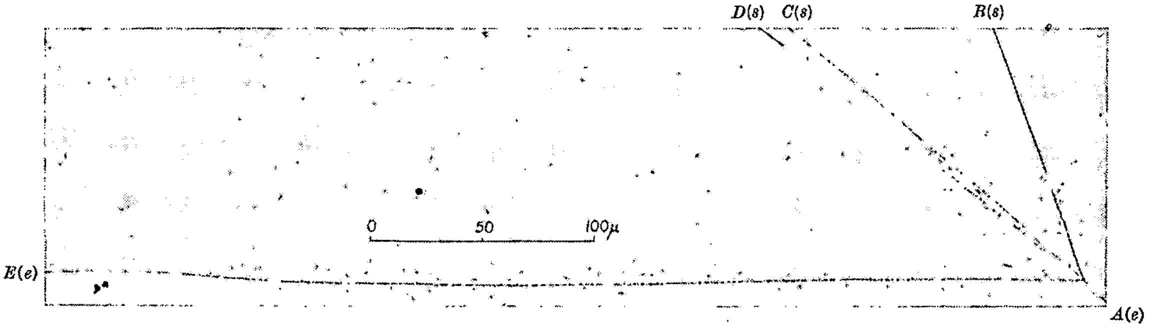

Fig. 3. MOSAIC OF 20 PHOTOMICROGRAPHS OF COLLIMATED TYPE OF STAR IN *B*2 EMULSION. TRACK *A*, RECOIL FRAGMENT; *B*, α-PARTICLE; *C* AND *D*, PROTONS OR α-PARTICLES; *E*, α-PARTICLE (ENERGY 36 MEV.)

The Fermi gas and liquid-drop models lead to considerably higher energies (500 MeV. or more) for $\overline{T} = 5$ MeV.

It is interesting to note that in the pure Bohr type of process the particles should be emitted under arbitrary angles; however, the angular distribution of tracks in a number of the stars show marked deviations from spherical symmetry, and probably these disintegrations are characterized by the fact that thermal equilibrium is never fully attained. Fig. 3 shows an extreme example of such a star. The probability that all four tracks were ejected under arbitrary angles is calculated as less than 1 in 10^6. However, since the recoil nucleus shows considerable momentum, and the ejected particles are of relatively low energy (20 or 30 MeV.), it is doubtful if this process is of the pure Heisenberg type, as observed in cloud chambers[3].

I should like to express my sincere thanks to Dr. J. L. Michiels, for a valuable discussion of the above material.

Adsorption Isotherms from Chromatographic Measurements

IT has been shown[1] that adsorption isotherms can be calculated with good accuracy from chromatographic data, utilizing the measured concentrations (c_v) of eluted solute after developing the original band with v c.c. of pure solvent. Use is made of the equation

$$q = f_{(c)} = (\mu_c + v.c_v)/x_t - \alpha.c_v, \quad . \quad (1)$$

where q is the amount of solute adsorbed per gm. of adsorbent, x_t is the total amount of adsorbent in the column (gm.), α is the pore space of the adsorbent (c.c./gm. adsorbent), μ_c is the total eluate after the point of concentration c.

In the case of strongly coloured solutes, however, where the movement of the front boundary of the chromatographic band can be followed easily, it is simpler to obtain the adsorption isotherm from the volume v of pure solvent used and from the amount of adsorbent x_f through which the coloured front has travelled from the top of the column.

The position of the front is governed by equation 1 in the form:

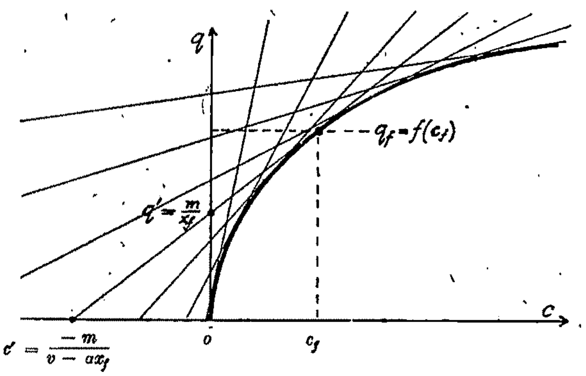
$$m = q_f.x_f - (v - \alpha x_f).c_f, \quad . \quad . \quad (2)$$

where m is the total amount of solute used. With m, v and x_f known, equation 2 represents a linear relationship between q and c with a gradient $dq/dc = (v - \alpha.x_f)/x_f$. However, as shown by De Vault[2] and by Weiss[3]

$$(v - \alpha.x_f)/x_f = [df_{(c)}/dc]_{c = cf}.$$

Thus equation 2, taken as a function of the variables q and c, corresponds to the tangent to the adsorption isotherm $q = f_{(c)}$ at the point q_f, c_f, and, with a sequence of coexistent values of v and x_f, equation 2 gives a family of straight lines, from which the adsorption isotherm can be easily constructed as the envelope.

The relative accuracy of the equilibrium values so obtained is approximately that of v and x_f, which, for a well-made column, can be determined to at least ± 1 per cent. This method thus gives the complete adsorption isotherm without requiring a single concentration measurement by just following the movement of the front boundary, and this with an accuracy at least equal to that of the best classical methods of measuring adsorption equilibria.



ADSORPTION ISOTHERM AS ENVELOPE OF THE FUNCTION $m = x_f.q - (v - a.x_f).c$

Slip Flow in Granular Beds

THE Poiseuille type of equation for capillaries of any shape takes the form,

$$u_e = \frac{m^2}{k_0\eta} \cdot \frac{\Delta p}{L_e} \quad . \quad . \quad . \quad . \quad . \quad (1)$$

for capillaries of any cross-section, where $k_0 = 2$ and $m = r/2$ for a circular capillary of radius r, and k_0 has generally values between 2 and 3 for other shapes[1]. Application of this to granular beds follows by putting $u = u_e \,.\, \varepsilon \,.\, L/L_e$, $m = \varepsilon/S\sigma(1-\varepsilon)$, $k = k_0 \,.\, (L_e/L)^2$, whence

$$u = \frac{\varepsilon^3}{(1-\varepsilon)^2} \cdot \frac{\Delta p}{k\eta S^2\sigma^2 L} \quad . \quad . \quad . \quad (2)$$

k is known as Kozeny's constant, and is approximately equal to 5 [1,2], Δp is pressure drop in dynes/cm.^{2}, and other symbols are as in the paper of Lea and Nurse[2].

When slip takes place in a capillary, giving a velocity, u_0, at the wall, this must be added to the right-hand side of (1). Now, by balancing momentum transfer and pressure difference, Millikan[3] obtained an expression for u_0 in a circular capillary in terms of a coefficient of external friction, β. In brief, tangential force on wall, $F' = 2\pi r L_e \beta u_0 = \pi r^2 \,.\, \Delta p$. This is readily generalized to non-circular capillaries, giving

$$u_0 = \frac{m}{\beta} \cdot \frac{\Delta p}{L_e} \quad . \quad . \quad . \quad . \quad (3)$$

The Poiseuille type of equation, corrected for slip, thus becomes

$$u_e = \frac{m^2}{k_0\eta} \cdot \frac{\Delta p}{L_e} \cdot \left(1 + \frac{k_0\eta}{m\beta}\right) \quad . \quad . \quad (4)$$

Millikan further showed that β is given by

$$\beta = \tfrac{1}{2}\, \rho\bar{c} \div \left(\frac{2}{f} - 1\right) \quad . \quad . \quad . \quad . \quad (5)$$

where f is fraction of molecules striking capillary walls which are diffusely reflected. Thus the slip correction factor $1 + k_0\eta/m\beta$ becomes

$$1 + \frac{2k_0\eta}{m\rho\bar{c}} \cdot \left(\frac{2}{f} - 1\right) \quad . \quad . \quad . \quad (6)$$

By substituting $m = \varepsilon/S\sigma(1-\varepsilon)$ this becomes a slip correction factor for granular beds,

$$1 + \frac{S\sigma(1-\varepsilon)}{\varepsilon} \cdot \frac{2k_0\eta}{\rho\bar{c}} \cdot \left(\frac{2}{f} - 1\right) \quad . \quad (7)$$

which must be multiplied into the right-hand side of (2). The first introduction of a slip correction factor of this form was made by Rigden[4], but he applied it in the form used for circular capillaries, for which $k_0 = 2$, whereas, for granular beds, k_0 appears to lie between 2·5 and 3, that is, the correction should be larger than that used by Rigden. Lea and Nurse[2] adopted the Chapman equation for viscosity, $\eta = 0{\cdot}5\ \rho\bar{c}\lambda$, where λ is molecular mean free path, in which case (7) takes the form

$$1 + \frac{S\sigma(1-\varepsilon)}{\varepsilon} \cdot k_0\lambda \left(\frac{2}{f} - 1\right) \quad . \quad . \quad (7a)$$

but wrote it in the form

$$1 + \frac{S\sigma(1-\varepsilon)\,Z\lambda}{\varepsilon} \quad . \quad . \quad . \quad . \quad (7b)$$

and evaluated Z experimentally, finding values between 2·73 and 4·07, averaging about 3·3.

By comparing (7a) and (7b), it can be seen that

$$Z = k_0\left(\frac{2}{f} - 1\right)$$

Now, Rigden used Millikan's value, $f = 0{\cdot}89$; but recently Brown, DiNardo, Cheng and Sherwood[5] have shown that $f = 0{\cdot}84$ is a more acceptable value in circular capillaries. It is of interest to calculate Z for both values of f and for $k_0 = 2$, 2·5 and 3.

$f \diagdown k_0$	2·0	2·5	3·0
0·89	2·50	3·12	3·75
0·84	2·76	3·45	4·13

Thus, on the whole, values of k_0 between 2·5 and 3 give better agreement with experiment than Rigden's assumption that $k_0 = 2$.

It is important to note here that there is no need to introduce a mean free path into (7), and that it is better to express it entirely in terms of experimental quantities by substituting

$$\bar{c} = \sqrt{\frac{8}{\pi} \cdot \frac{RT}{M}}$$

giving

$$1 + \frac{S\sigma(1-\varepsilon)}{\varepsilon} \cdot \sqrt{\frac{\pi M}{2RT}} \cdot \frac{k_0\eta}{\rho} \cdot \left(\frac{2}{f} - 1\right) \quad . \quad (7c)$$

It should also be noted that, if Δp is a large fraction of the initial pressure, u must be replaced by the mass velocity, $G = \rho u$, and equation (2) is easily shown to assume the form

$$G = \frac{\varepsilon^3}{(1-\varepsilon)^2} \cdot \frac{\rho_m \Delta p}{k\eta S^2\sigma^2 L}, \quad . \quad . \quad . \quad (8)$$

where ρ_m is the mean gas density before and after the bed and is equal to $\frac{1}{2}(\rho_1 + \rho_2)$. At the same time, ρ_m must be substituted for ρ in all the slip factors (7).

Molecular Flow of Gases in Granular Beds. When, in (7b),

$$\frac{S\sigma(1-\varepsilon)Z\lambda}{\varepsilon} \gg 1, \text{ that is, } \frac{Z\lambda}{m} \gg 1,$$

slip flow passes to molecular flow and the unity term in slip factors (7) can be neglected. Multiplying the second term of factor (7c) into the right-hand side of equation (8), we get

$$G = \frac{k_0}{k} \cdot \sqrt{\frac{\pi M}{2RT}} \cdot \left(\frac{2}{f} - 1\right) \cdot \frac{\varepsilon^2}{(1-\varepsilon)S\sigma} \cdot \frac{\Delta p}{L} \quad (9)$$

This differs from the equation put forward by Holmes[6] in two respects: (i) a factor k_0/k is introduced, which we have seen equals $(L_e/L)^2$ and appears generally to lie between 1·5 and 2. (ii) A factor $\sqrt{\frac{\pi}{2}} \cdot \left(\frac{2}{f} - 1\right)$ takes the place of $\frac{8}{3}\sqrt{\frac{2}{\pi}}$. Since Brown, DiNardo, Cheng and Sherwood find $f = 0{\cdot}77$ best fits molecular flow in circular capillaries, the two expressions are about equal.

High-Frequency Permeability of Ferromagnetic Materials

IN view of the possibility of obtaining fuller information about the domain structure of ferromagnetics, by measurements of permeability at high frequencies, a method has been developed of measuring the effective reversible permeability of ferromagnetic materials in wire form over a fairly wide range of frequencies. A comprehensive review of earlier work has been given by Allanson[1], and apart from the early work of Arkadiew[2], who used a spark-gap source, no measurements of permeability have been recorded at frequencies higher than about 2,000 Mc./s.

Of the methods suggesting themselves for measurements at microwave frequencies, reflexion methods were found to be unsuitable[3] for metallic conductors, and the measurement of Q-factors of ferromagnetic films seemed to present experimental and theoretical difficulties.

In our method the permeability is deduced from measurement of the difference, $\Delta\alpha$, in the attenuation constant of a coaxial transmission line when the inner conductor, made of the ferromagnetic material under test, is replaced by a non-magnetic material of the same dimensions. It may be shown that

$$\Delta\alpha = \text{constant} \times \left(\sqrt{\frac{\mu}{\sigma_1}} - \sqrt{\frac{1}{\sigma_2}}\right),$$

where σ_1 and σ_2 are the conductivities of the ferromagnetic and non-magnetic materials respectively, and μ is the permeability.

The attenuation constants are determined from standing-wave measurements for different reactive terminations and are deduced directly from a circle diagram[4]. A pulsed oscillator is used to enable amplification of the rectified signal and accurate measurement of standing-wave ratios between 1 and 100 to be made. The method is rapid in operation and particularly suitable for use in the microwave region between about 2 and 20 cm. The present measurements, however, have been restricted to those frequencies for which suitable oscillators could be obtained.

Results have been obtained over the range from 8 to 14 cm., on a low-carbon content iron wire (0·04 per cent carbon), and a steel wire (0·50–0·55 per cent carbon), both specimens being tested in the hard-drawn (bright) condition and also after white annealing. Measurements have also been made with a commercial nickel wire (higher than 99·5 per cent nickel). The results, together with the D.C. initial permeabilities, are given in the accompanying table :

Frequency (Mc./s.) Wave-length (cm.)	D.C.	2300 13	2600 11·5	3000 10	3400 8·8
Iron, bright	101	50	65	63	61
Iron, white annealed	140	41	60	67	65
Steel, bright	65	38	34	39	25
Steel, white annealed	102	31	31	28	28
Nickel	13	7	8	10	8

The probable error in these results is of the order of 10 per cent.

The measurements are now being extended to other frequencies and ferromagnetic materials. A fuller account of these measurements, together with their bearing on the theoretical considerations advanced by Becker[5] and Kittel[6], will be published in due course.

Decay of Luminescence due to Forbidden Optical Transitions

IT is well known that the exponential, temperature-independent decay of luminescence in solids such as sulphides and silicates of zinc and ruby is characteristic of forbidden optical transitions within the specific luminescence emission centres, and the mean life-time of such decays can be of the order of milliseconds in these materials[1,2]. The nature of these transitions in the chromium centres of ruby has been thoroughly studied by Thosar[3], and the resulting decay of luminescence by Garlick and Wilkins[2]. In 1943, Dr. A. F. Wells, working in this laboratory, found that manganese centres in certain fluoride crystal lattices produced such decays with time constants of the order of 10 sec.$^{-1}$, that is, the mean decay time being 100 msec.

We have recently studied the function of rare earth impurity in some silicate phosphors, and find that the emission centres formed by inclusion of europium ions in strontium silicate give rise to an exponential decay of luminescence which is independent of temperature (experimental range 90°–600° K.) and has a mean life-time of 2·3 sec., this decay being preceded by a faster component of very short life-time. Both components appear for excitation by 3650 A. and by 2537 A., but in addition the shorter wave-length produces a long-duration exponential decay of phosphorescence which is strongly dependent on temperature and is associated with a thermoluminescence characteristic of a single depth of electron trap of 0·75 eV. as derived from the relations developed by Randall and Wilkins[4]. Excitation by the short wave-length also causes photoconduction, but this is not closely associated with the luminescence processes in the material. Under all wave-lengths of excitation the emission spectrum consists of a broad band in the visible region with maximum in the green, and does not compare with the usual spectra of salts and solutions of salts of europium[5].

So far, studies have been of a preliminary nature and little is known of the location of the europium ion in the silicate lattice. The studies of electron trapping show that the traps are specific to the centres and may be either within each centre or very near it. The efficiency of the luminescence is about 0·1 of that for a willemite phosphor excited by the short wave-length of 2537 A.

We have found such low transition probabilities in dye molecules when adsorbed on to solid surfaces after the method of Travniček[6], the mean life-times being of the order of 1·6 sec. for such molecules as carbazol, æsculin and phenanthrene. Such decay processes may also be followed by a temperature-dependent decay of longer duration.

Bond-Strengths of Methyl-Iodine and Methyl-Magnesium

THE heats of the following reactions in ether solution have been determined calorimetrically :

$$CH_3 - MgI + I_2 = CH_3I + MgI_2 - 45{\cdot}4 \pm 1{\cdot}0 \text{ kcal.}$$

$$2CH_3{-}Mg{-}I + I_2 = \underset{\text{(gas)}}{C_2H_6} + 2MgI_2 - 103{\cdot}4 \pm 3 \text{ kcal.}$$

Using these values, and published data[1] for the heats of atomization of solid iodine, for the bond-strength $D(CH_3-CH_3)$ and for the latent heats of volatilization of ethyl ether and methyl iodide, the bond-strength is calculated

$$D(CH_3 - I) = 54{\cdot}75 \pm 1{\cdot}4 \text{ kcal.},$$

in good agreement with the value of 54 kcal. obtained from kinetic data[2].

A (less reliable) value of the bond-strength

$$D(CH_3 - Mg) = 67{\cdot}0 \text{ kcal.}$$

can also be computed from the calorimetric data.

DIFFRACTION OF X-RAYS BY THE ALLOY $AuCu_3$

THE alloy $AuCu_3$ has an ordered structure below 391° C. If a disordered alloy is heat-treated below this temperature, superlattice lines appear on X-ray powder photographs, and the development of the perfectly ordered structure can be followed by observation of these superlattice lines; they are diffuse at first and increase in sharpness as the heat-treatment progresses, until they become as sharp as the main lines.

A simple explanation of this phenomenon is that the domains of similar order (anti-phase domains) are initially much smaller than the crystal grains in which they exist; on this basis, Jones and Sykes[1] showed that it should be possible to derive the sizes of the anti-phase domains from the breadths of the superlattice lines. Detailed investigation showed, however, that different lines gave different results, and the problem remained unsolved.

Wilson[2] has produced a method of calculating the diffraction effects given by such an alloy, and has shown that the breadths of the various superlattice lines will be dependent upon the way in which one domain is bounded by its neighbours; he tried the effect of imposing certain conditions on the boundaries and found one model that gave fair agreement with Jones and Sykes' results. He pointed out, however, that it was possible that other models may give as good agreement or even better.

We have attempted to test Wilson's theory by taking X-ray oscillation photographs of a single crystal; such photographs contain much more evidence than powder photographs and so should provide a much more stringent test of the theory. Similar considerations have led Strijk and MacGillavry[3] also to carry out experimental work on a single crystal to test a theory of their own[4]. Their theory is rather different from Wilson's, and their experimental results do not fit in perfectly with either. We believe, however, that their experimental methods are not well suited to differentiate between the two theories, as the following considerations show. MacGillavry and Strijk's theory would lead to sharp reciprocal points for the main reflexions and diffuse spots all of the same shape and with cubic symmetry for the superlattice reflexions; Wilson's theory leads to a more complicated representation which is shown in Fig. 1. MacGillavry and Strijk used a rod-like crystal with its length approximately in the [110] direction, and they investigated the distribution of intensity only in the plane perpendicular to [110]. Therefore, they have not checked that the spots have cubic symmetry, as their theory demands; nor have they disproved Wilson's theory, since this leads to similar shapes for all spots with $h + k = 0$.

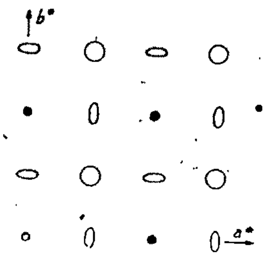

Fig. 1. RECIPROCAL LATTICE OF $AuCu_3$ ACCORDING TO WILSON'S THEORY

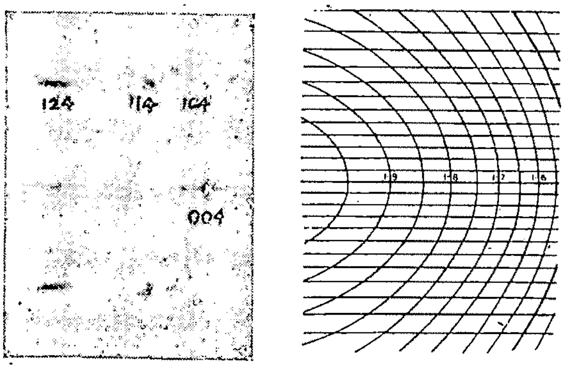

a b

Fig. 2 a and b. PORTION OF OSCILLATION PHOTOGRAPH OF $AuCu_3$ AND CORRESPONDING PORTION OF BERNAL CHART

Our crystal is smaller than that used by MacGillavry and Strijk; it gives main reflexions that are quite small, and so the shapes of the superlattice reflexions stand out clearly. Preliminary results show qualitative agreement with Wilson's theory; this is shown by Fig. 2, which is part of an oscillation photograph about the [100] axis.

It will be seen that the spots are not all of the same shape; for example, 114 is elongated at an angle to the layer line and 124 is elongated along the layer line. Such an effect cannot be produced by differences in the geometrical conditions for reflexion due to difference in θ. Moreover, the slope of the spot 114 is about the same as that of the curves on the Bernal chart (Fig. 2b) at the same point, which means that the elongation is parallel to one of the reciprocal axes. In this respect, the results are in accordance with the reciprocal lattice shown in Fig. 1.

Oscillation photographs do not provide a complete test, as the spots recorded represent projections of the reciprocal-lattice spots on to a plane. We are, therefore, undertaking a more detailed investigation of sections of the spots, and this should provide quantitative evidence by means of which the two theories can be adequately tested.

[3] Strijk and MacGillavry, *Physica*, **12**, 129 (1946).
[4] MacGillavry and Strijk, *Physica*, **11**, 369 (1946).

IN treating the integral breadths of the lines in the powder photographs of $AuCu_3$ obtained by Jones and Sykes[1], it was not necessary to consider the actual shapes of the regions of high intensity in the reciprocal lattice, the apparent particle-size of the *hkl* reflexion being given directly by

$$\varepsilon = (J_0 V_0)^{-1} \int V_t J_t dt, \qquad (1)$$

where V_t is the volume common to the crystal and its 'ghost' shifted a distance t in the *hkl* direction, and J_t is the mean value of the product FF^* for two cells separated by a distance t in the *hkl* direction[2]. The distribution of intensity in the reciprocal lattice may be obtained from the same functions. If a, b, c

are the cell edges, U is the volume of the unit cell, $V(x, y, z)$ and $J(x, y, z)$ are the values of V and J corresponding to the displacement xa, yb, zc, and ua^*, vb^*, wc^* are distances measured from the point hkl of the reciprocal lattice, the intensity of reflexion is proportional to

$$H(u,v,w) = U^{-1}\iiint V(x,y,z)\, J(x,y,z) \exp\{2\pi i\,(ux+vy+wz)\}\, dx dy dz. \quad (2)$$

This expression was derived in connexion with line broadening in hexagonal cobalt[3], where, however, it was written in the form of a summation. In many cases the variation of V_t or $V(x,y,z)$ can be neglected in comparison with the more rapid variation in J_t or $J(x,y,z)$.

Equation 2 can be evaluated for several of the models suggested[2] for the occurrence of mistakes in $AuCu_3$. For the fifth model, in which gold atoms avoid one another, it gives[4]

$$H(u,v,w) = N(\text{Au-Cu})^2 \cdot \frac{\alpha}{\alpha^2+\pi^2u^2} \cdot \frac{\alpha}{\alpha^2+\pi^2v^2} \cdot F(w) \quad (3)$$

for the superlattice reflexions having h and k both odd or both even; if k and l or l and h are both odd or both even, the variables u,v,w are appropriately permuted. The factor $F(w)$ is the 'normal' variation of intensity in the reciprocal lattice, being practically zero for w differing appreciably from zero, and α is the probability of a mistake in a distance a. This leads to the type of reciprocal lattice pictured by Edmunds, Hinde and Lipson[5]. For the sixth model, which is similar except that the gold atoms merely tend to avoid one another, the integrations necessary to evaluate Equation 2 cannot be easily performed, but qualitatively the effect will be to give the disks a finite thickness, the relative amount of the thickening depending on the ratio of the probability α of a mistake in which gold atoms avoid one another to the probability γ of a mistake in which they do not.

This model thus accounts qualitatively for the results of Strijk and MacGillavry[6] and of Edmunds, Hinde and Lipson. It is possible to make a semi-quantitative comparison with the former, since they use their experimental data to evaluate the function $J(x,y,z)$, or rather the section of it by the plane $y+z = 0$, for reflexions of the type $hk\bar{k}$. The theoretical value of J for these reflexions is[3]

$$J(x,y,z) = (\text{Au-Cu})^2 \exp\{-2\alpha(|y|+|z|) - 4\gamma r/3\}, \quad (4)$$

where $r^2 = x^2 + y^2 + z^2$. In polar co-ordinates in the section evaluated

$$J(r,\theta) = (\text{Au-Cu})^2 \exp\{-(2\sqrt{2}\alpha\,|\sin\theta\,| + 4\gamma/3)r\}, \quad (5)$$

which may be compared with the contours given in Strijk and MacGillavry's Fig. 7. Equation 5 suggests that the contours of constant J will all be of the same shape, given by

$$r^{-1} = 4\gamma/3 + 2\sqrt{2}\alpha\,|\sin\theta\,|, \quad (6)$$

and that their sizes will be proportional to log J. The contours obtained by Strijk and MacGillavry, normalized to $r = 1$ for $\theta = 45°$, lie within the area shaded in Fig. 1, so that there is little variation in shape. The full line is the curve given by Equation 6, the values of α and γ obtained from Jones and Sykes' powder photographs being used. The agreement is fair, being about as good as that obtained experimentally for different reflexions. In Fig. 2 log J is plotted against the actual radii for $\theta = 45°$. A straight line can be drawn through the points for the smaller values of J, those for the larger lying below it. Strijk and MacGillavry give reasons for supposing that the larger values of J are too low, so that their experiments are not inconsistent with the model proposed to explain the powder photographs of Jones and Sykes.

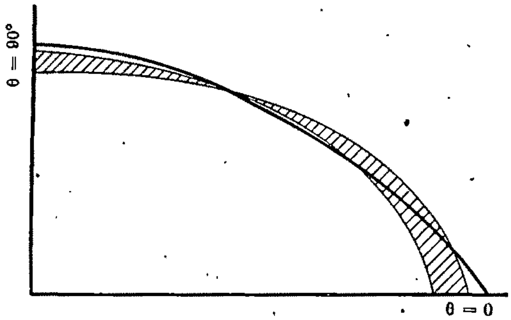

Fig. 1. SHAPES OF EXPERIMENTAL (SHADED AREA) AND CALCULATED (FULL LINE) CURVES OF CONSTANT J

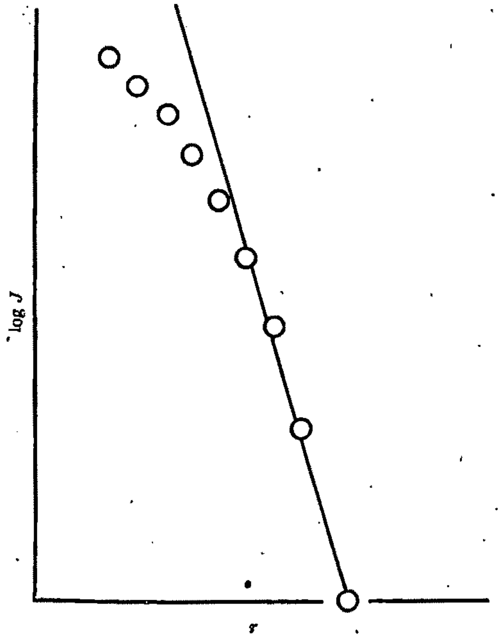

Fig. 2. EXPERIMENTAL (CIRCLES) AND CALCULATED (FULL LINE) MODE OF VARIATION OF LOG J WITH r

Further work is necessary, however, to establish the correctness or otherwise of this model. It is somewhat difficult to imagine the internal state of a crystal containing mistakes both on 100 planes, such that gold atoms do not come into contact, and on random planes, with no avoidance by the gold atoms. It may be necessary to modify the assumption that the probability of a mistake in any interval is independent of the position of other mistakes.

ELECTRODE PROCESSES

On April 9 and 10 a discussion on "Electrode Processes" arranged by the Faraday Society was held at Manchester. The meeting was attended by nearly two hundred people, including several distinguished overseas visitors.

Faraday Society discussions have often marked an important stage in the development of branches of physical chemistry, and it was at a very timely moment in the development of the subject of electrode processes for such a discussion to take place. It seems to be probable that the most important advance in experimental physical chemistry in the next decade will lie in the application to the science of the techniques of electronic engineering, developed particularly during the War, and the field of electrode processes may be one which will yield readily to attack by the new weapons; in fact, a most promising start has already been made. For this reason, a review of the subject at this stage will undoubtedly give great impetus to development along the more important lines.

Altogether, forty papers were presented at the meeting, and they were discussed in groups under the headings "General", "Hydrogen Overvoltage", "Deposition of Metals", "Oxygen Overvoltage" and "General Anodic Processes and Cell Reactions". An introduction to the whole discussion was given by Prof. W. F. K. Wynne-Jones (Dundee), and the various sections were introduced by Prof. Wynne-Jones, Dr. A. Hickling (Liverpool) and A. W. Hothersall (Woolwich). The president, Prof. W. E. Garner (Bristol), was in the chair throughout the meeting.

The subject of hydrogen overvoltage was taken first, and at this stage Prof. A. L. Ferguson (Ann Arbor) directed attention in his paper to the many unsolved fundamental problems associated with the interface between electrode and electrolyte, and to the difficulties in interpreting data obtained by different methods.

A communication by Prof. A. Frumkin (Moscow) discussed the mechanism of hydrogen discharge on the basis of extensive experimental work. The data are interpreted as proving that the discharge of hydrogen ions is the slowest stage in the evolution of hydrogen from acid solutions on mercury, but that subsequent stages, for example, the combination of hydrogen atoms to form molecules, may assume importance with low overvoltage cathodes. The slow-discharge theory was the basis of a theoretical contribution by Dr. J. Weiss (Newcastle-on-Tyne), in which the discharge was considered as the transfer of a proton from the hydrated to the surface-adsorbed state. In a lively discussion the slow-discharge theory was strongly criticized by some speakers, one of the points raised being the apparent absence of a satisfactory relation between the work function of the metal and the value of the overvoltage. The chief alternative theory is the slow combination of hydrogen atoms at the cathode. It was regrettable that Prof. Frumkin was unable to be present in order to contribute to the discussion on this controversial issue. Prof. Garner suggested that a compromise between the two theories would probably be more satisfactory than either of them taken by itself.

J. N. Agar (Cambridge) suggested an analysis of overvoltage data in the manner adopted for rate constants, deriving a 'heat of activation' and an 'entropy of activation', as an examination of these parameters might throw some light on the possible discharge mechanism.

Dr. F. P. Bowden (Cambridge) and K. E. W. Grew (Cambridge) presented data on overpotential measurements at very low current densities on mercury which demonstrate that Tafel's equation, whatever its general validity, is in any event closely obeyed by mercury cathodes over the current density range 10^{-10}–10^{-2} amp./cm.^{2}. The same authors re-investigated the capacity of the double layer on mercury in sulphuric acid solution by the charging-time method. Their value (20 μf./cm.^{2}) is in close agreement with measurements by different procedures, but considerably higher than previous values obtained by the same method. It was pointed out in the discussion that, in spite of the agreement between different determinations, the uncertainty in the value of this quantity is still considerable, for example, a value of 12 μf./cm.^{2} was preferred by Dr. Hickling.

The behaviour of palladium electrodes during the discharge of hydrogen was the subject of a paper by H. P. Stout (Saltcoats). P. M. Bryant (Bristol) and G. E. Coates (Bristol) described an investigation of the polarization of platinized platinum electrodes, where an ageing effect of the electrodes was discovered. Periodic changes in the behaviour of anodically polarized platinum electrodes were discussed by Dr. J. A. V. Butler (London) and G. Armstrong.

In the group of "General" papers the subject of diffusion at the electrodes, of importance in the theory of concentration polarization, was treated mathematically by J. N. Agar and by B. Levich (Moscow). The kinetics of rapid electrode reactions have been studied experimentally by J. E. B. Randles (Birmingham), the analysis of the results leading to values for rate constants of electrode reactions.

In an important theoretical contribution, T. B. Grimley (Bristol) and Prof. N. F. Mott (Bristol) calculated from first principles the potential difference at the interface between a solid and an ionic solution, the example chosen being that of the silver–silver bromide electrode.

There were several papers on the cathodic deposition of metals. The relation between the structure of the deposit and the conditions of deposition was examined by electron diffraction experiments by Prof. G. I. Finch (London), H. Wilman (London) and L. Yang (London). Two communications by T. P. Hoar and J. N. Agar dealt with the theoretical analysis of electrical conditions in plating baths. Polarization in the electrodeposition of metals was discussed by G. E. Gardam (London), who showed that the physical form of the cathode metal deposit may influence the polarization, the cause being the difficulties of disposing of the new atoms in the grain lattice.

The mechanism of cathodic metal deposition was investigated by Prof. J. Heyrovský (Prague), using a new modification of the polarographic technique by which electrodeposition involving an irreversible discharge may be recognized. The results show that all one-electron discharges are reversible, but that most processes with more than one electron transfer are irreversible; and it is deduced that the electrons are transferred successively.

The first paper on the subject of anode processes was contributed by Dr. A. Hickling, who directed attention to anomalies observed in some anodic reactions; for example, the Kolbe reaction, where processes occur at a high positive potential in preference to other possible reactions requiring a lower potential. There was considerable discussion on this, the question being whether the phenomenon could be explained by some specific adsorption mechanism, or whether a more fundamental electrochemical problem was raised by it.

A number of contributions dealt with determinations of oxygen overvoltage. A considerable degree of reproducibility has been achieved in some of the studies (± 0·01 to ± 0·03 V.), but agreement between different laboratories is not yet satisfactory. It was urged earlier in the discussion by Sir Charles Goodeve that in overvoltage measurements more attention should be given to the influence of the procedure of measurement on the results. The effect on the oxygen overvoltage of electrode material current density and time for aqueous solutions was examined by Dr. A. Hickling and S. Hill, and that of solvent variation (also on hydrogen overvoltage) by Dr. J. O'M. Bockris (London).

The last group of papers was devoted to other anodic processes and cell reactions in general, several communications dealing with anodic polarization of metal electrodes by surface oxides. M. Haïssinsky (Paris) pointed out that hydrogen peroxide oxidations may lead to chemically different products from anodic oxidations, which does not agree with the general theory of intermediate hydrogen peroxide formation in anodic oxidations.

An interesting contribution by Prof. H. J. C. Tendeloo (Wageningen) showed that electrode potentials are not only of applied but also of direct interest to biologists, and presented data about the application of electrochemical theory to calculate the potentials of plant roots.

A brief summary of this kind cannot, of course, lay claim to either completeness or even impartiality in the selection of the points reported in it; but the complete proceedings of the meeting, including the papers read and remarks made in discussion, will be published in the *Transactions of the Faraday Society* as Volume 43 A (1947). V. GOLD

MILK, TINNED FOODS AND BREAD

AT the Health Congress of the Royal Sanitary Institute recently held at Torquay, Section E (Food and Nutrition) met jointly on June 6 with the Food Group of the Society of Chemical Industry. Three papers were given at this session, each dealing with an important and topical aspect of food in relation to health. Prof. H. D. Kay (president of the Section) directed the attention of the meeting to the slow decline, that began some years before the War and was acutely accentuated during the winter months of the war years, in the compositional quality, and therefore in the nutritional value to the consumer, of market milk. The only reason for the existence of the milk industry is the fact that cows' milk is a valuable human foodstuff. Anything, therefore, causing a decrease in its nutritional value is of major importance not only to the consumer but also to all engaged in the industry, whether producers or distributors.

The insidious but now well-established decline which began to declare itself some years before the War is a diminution both in the fat and the non-fatty solids content of milk (when figures are averaged over the year). This amounts to an increase in its water content; but it is not due to adventitious watering—experimental surveys have shown that there are few indeed of the farmers of Great Britain who are guilty of extending the volume of the milk in this way. The main cause of this slow decline is the increased use, in breeding, of what Prof. Kay called 'watery' bulls, that is, bulls selected merely on account of the high milk yields of their female relatives, without regard for the *quality* of the milk. 'Watery' bulls of both the Friesian and the Shorthorn breeds are involved; the rapid increase in recent years in the number of relatively poor-quality Friesian bulls is well known.

As regards the acute fall in non-fatty solids to well below the 'legal' presumptive limit of 8·5 per cent, a fall which occurred during the late winter months (January to April) in very many herds during the War years and since, and which reached in April 1947, in some districts, the lowest figures yet recorded, it has been conclusively demonstrated by experiments at the National Institute for Research in Dairying during the past two years that the main cause is a deficiency of winter feeding-stuffs. It is in the valuable proteins of the milk that this compositional defect is most apparent, and not in the fatty portion. An unexpected finding is that shortage of energy (calories or 'starch equivalent') in the cows' diet is more serious in its effects in diminishing the milk protein than is shortage of protein, provided the diet contains sufficient energy. The level of non-fatty solids in the milk returns to normal, or even goes above normal, within a few days of the cows going out to grass in the spring.

Prof. Kay suggested that the quickest and most satisfactory way of reversing the slow decline in average milk quality would be to pay milk producers on the basis of compositional quality and not, as at present, merely on volume. The suggested method of payment, which is already applied in several countries abroad and presents no insuperable difficulties, would reimburse the dairy farmer for making those changes in breeding and management of his herd which would, if persisted in over a few years, achieve again the higher milk quality so desirable from the point of view of human nutrition. The acute fall in *winter* milk quality, which even to-day does not occur in adequately fed, well-managed herds, can only be dealt with by an improvement in the supply of winter feeding-stuffs. Even if more high-energy concentrates can be imported—and Prof. Kay thinks that every endeavour should be made to increase such imports—it will also be necessary to improve the quality and quantity of home-produced fodders for winter consumption, such as high-quality hay, silage made from young grass or from cereal-legume mixtures, kale, kale silage, dried grass, etc. A great deal can still be done in this direction on a very large number of dairy farms.

Mr. Stewart Swift (Oxford) spoke of the increasing anxiety with which public health and sanitary authorities are viewing the steady decline in milk quality; it concerns them not only from the point of view of human nutrition but also on legal grounds. He hoped that no time would be lost in applying the lessons derived from the surveys and the experimental work. Principal A. W. Ling (Seale Hayne) mentioned work carried out under his direction in the Bristol Province on the relation between low-quality hay and the decrease in the compositional quality of milk; but emphasized the very serious difficulties under which the present-day dairy farmer is labouring.

The present state of our knowledge regarding certain major microbiological problems of the food canning industry was discussed by Mr. T. E. Bashford (London). The ideal heat process for any given canned food is one which, while of sufficient duration and temperature to render the product 'commercially sterile', yet has a minimal effect on its quality, nutritional value and on the attractiveness of its flavour. 'Commercial sterility' does not mean absolute sterility, since the finished pack may contain viable spores of thermophilic bacteria which do not give rise to difficulties so long as the cans are marketed under ordinary conditions of climate. Two main factors determine the adequacy of a process, namely, the rate of penetration of heat into the least accessible part of the contents of the can, and the thermal death-time of the most resistant of the organisms capable of causing spoilage or danger to health. The thermal death-time curve for *Cl. botulinum*, the most heat-resistant and dangerous of the food-poisoning organisms, has been very carefully determined, and in practice it has been found normally satisfactory if the heat exposure, determined as regards temperature by that reached in the slowest-heating portion of the can, has a 'lethal value' about three times that needed to destroy *Cl. botulinum*. In some cases, particularly where the pack has to go to tropical or semi-tropical countries, six to seven times the minimal lethal conditions for *botulinum* are used.

Mr. Bashford described how 'lethal rates' and 'lethal values' are determined, and showed how accurate determination of temperatures, at any part of a can during processing, can be carried out by means of thermocouples inserted into the pack before autoclaving. He also dealt with post-processing infection of the can contents through minute holes which are sometimes left, particularly if the dimensions of cover and body do not conform to quite close mechanical tolerances, when the cans are being sealed. Organisms from the cooling water or from the air may be drawn through the defective seams as the internal pressure of the can falls during cooling. As a precautionary measure, chlorination of the cooling water is now extensively used in canneries, with marked reduction in the proportion of cans that become 'blown'. The importance was stressed of the highest possible degree of microbiological cleanliness, not only in the food and other raw materials, such as sugar, before canning, but also in the whole of the canning plant.

The realization by progressive millers and bakers of the same need for microbiological cleanliness was mentioned by Dr. E. C. Barton-Wright, who gave an interesting account of some microbiological aspects of flour-milling and baking. Beginning with the quorn, which was a type of property having a very special legal position in ancient society, Dr. Barton-Wright spoke of the evolution of power-driven mill stones and then of the sudden change, some seventy years ago, to the equivalent but fundamentally very dissimilar machinery which, with further modifications, carries out the modern, complicated process of flour milling. The all-important factor in the prevention of microbiological spoilage of wheat or flour is the moisture content, and experimental work in this field was described in some detail. Whereas wheat can be stored for long periods with complete safety at moisture content less than 16 per cent, with flour the conditions are more complex. Though moulds do not grow in flour which has a moisture content of less than 16 per cent, they nevertheless remain metabolically active when the moisture content is between 16 and 14 per cent, and will attack first the saturated acids and later the unsaturated fatty acids in the fat or oil naturally present in the flour, with disastrous results as regards baking quality and flavour. The metabolic activity of the moulds ceases below about 14 per cent moisture, but there is a danger of oxidative rancidity setting in if the moisture content is too far reduced, particularly in high-extraction flours. It is better, therefore, to store flour at a moisture content between 11 and 12 per cent, when the keeping life of a strong white flour under reasonably cool conditions may be as long as ten years. Even high-extraction flours, for example, National flour of 85 per cent extraction, will keep its quality under these conditions for several months.

Dr. Barton-Wright discussed the conditions controlling the growth of moulds on and in baked loaves. Mould infection is almost always external, and simple precautions in the bakehouse, the delivery van and the home should prevent it. The methods of prevention of the troublesome bacterial disease of bread known as 'rope', usually caused by *B. subtilis* spores in the flour which are not destroyed by the baking process, was described. More acid conditions during baking tend to prevent, and less acid conditions to foster, an outbreak of 'rope'.

A lively discussion followed, in which Mr. C. Ash (Coventry), Dr. J. Sword (Glasgow), Mr. D. H. F. Clayson (London), Mr. Hooper (Bristol) and others took part. It ranged over the effect of mastitis on milk quality, the alleged maldistribution of feeding stuffs for milk production, the absence of 'rope' in Scotland as a result of the more acid doughs used there, and the occasional presence in canned and preserved food of heat-stable toxins of bacterial origin.

WAR-TIME DEVELOPMENTS IN METALS AND ALLOYS

THE tenth Edward Williams lecture to the Institute of British Foundrymen was given by Sir Edward Appleton on "New Metals for Old". After a general discussion of the metallic state, Sir Edward discussed a number of aspects of metallurgy on which new light had been thrown in recent years.

The development of materials for war purposes has led to the introduction of new alloys, of which a steel containing carbon 0·4 per cent, nickel 13·5 per cent, chromium 13·5 per cent, tungsten 2·5 per cent, molybdenum 1·8 per cent, cobalt 10·5 per cent, niobium 3·4 per cent, may be mentioned as typical. This steel, developed for high-temperature services in the gas turbine, has a creep-rate of 0·2 per cent in 100 hours under a load of 5 tons per square inch at 800° C. Improvements in the nickel–chromium alloys have been effected by the addition of titanium, which brings about a dispersion of particles of titanium carbide. Nichrome is also improved from the point of view of creep resistance by the precipitation of a complex intermetallic compound of nickel, titanium and aluminium.

An iron–nickel alloy with 36 per cent of nickel and 5–8 per cent of chromium, together with a certain amount of titanium; has been developed where low thermal expansion, as, for example, in a tuning fork, is required. The magnetic properties of iron–silicon alloys used in transformers, etc., have been shown to be effected by the crystalline orientation of the grains. Better magnetic properties are found in a direction parallel to the edges of the cube than in any other, and a technique has been worked out to ensure that this orientation is, at any rate, largely obtained.

Another example of the development in magnetically soft material are the 'dust-cores' used in transformers and inductances for telecommunication work. Here, a constant permeability is desired. A reduction in the size of the particles greatly reduces the effective permeability, but stabilizes its value for different magnetic fields as well as reducing the loss due to eddy currents. A carbonyl iron in the form of spherical particles a few thousandths of a millimetre in diameter has been produced in Great Britain for the purpose.

Passing on to the magnetically hard materials, the enormous advances which have been made in this field were outlined; the value with some alloys of applying during the cooling a magnetic field which produces a large increase in the remanence in the direction of the applied field was pointed out. Here, as in the case of the anisotropic silicon-iron, it is important that the design should be such that the material is used in the favourable direction only.

In conclusion, what may be an extremely important development in cast iron was mentioned. This, in brief, is the treatment of the iron in such a way that the graphite formed is of the nodular type characteristic of black-heart malleable iron, which hitherto has only been possible after lengthy heat-treatment. F. C. T.

THE *ZOOLOGICAL RECORD*

THE appearance of volume 81 of the *Zoological Record*, dealing mainly with the literature of 1944, is worthy of special notice, for this comprehensive bibliography of zoological literature has been published regularly since its foundation in 1864. The *Record* is still mainly dependent on donations for its production, and until the Zoological Society of London assumed responsibility for its publication it underwent many changes in its direction which might have had a disastrous effect on a less hardy annual.

The object of the *Record* is to give a reference to every article or book of zoological importance throughout the world that has appeared in the previous year. During the War it was impossible to bring out the volumes to time, and at the moment there is a delay of nearly two years; but as soon as printing conditions are easier it is hoped to get back to the normal practice of completing the *Record* in the year following the literature to which it refers. The cost of producing such a work is, of course, far beyond the price at which it is sold, and it could scarcely hope to be self-supporting; but a further measure of support might be expected from professional zoologists, some of whom seem to be unaware of its existence. The complete volume, published at £4 (subscription rate £3 5s.), is more suitable for libraries, university departments, etc.; but the sections are issued separately as soon as they are ready, and since their cost ranges from only 2*s*., in the case of the smaller groups, to 6*s*. for Aves, and a maximum of 15*s*. for Insecta, it should be possible for any zoologist to provide himself with the literature of the group in which he is specially concerned.

There is a mistaken impression that the *Zoological Record* is only of interest to the systematist, but it is also invaluable to the comparative anatomist, the embryologist and the field naturalist; and publications concerned in a general way with genetics, ecology, and other branches of zoology are also included.

Each reference is allotted to one of the twenty odd sections into which the *Record* is divided, and then dealt with under three headings: (1) Titles, containing complete references to all articles arranged in alphabetical order of the authors' names; (2) Subject Index, giving a detailed analysis of the subjects dealt with in each article; and (3) Systematic Index, comprising a list of all the animals referred to in the section concerned, including those described as new forms, arranged in systematic order. This arrangement enables the reader to find the information regarding the current zoological literature of any group under the authors' names, under specific subjects, or under the scientific names of animals.

The nature of the service provided by the *Zoological Record* is illustrated in the following excerpt:

I. TITLES.
  66.—CHRISTENSEN, J. F. The oocysts of coccidia from domestic cattle in Alabama (U.S.A.), with descriptions of two new species. *J. Parasit.* Urbana, **27**, 1941, pp. 203–220. 2 pls. 1 text fig.
II. SUBJECT INDEX.
  STRUCTURE.
    SPOROZOA.
      Eimeria spp. (including new) from American cattle, CHRISTENSEN, **66**.
  ECOLOGY.
    PARASITISM: Hosts—
      MAMMALIA: *Bos taurus*, intestine (U.S.A.): *Eimeria alabamensis* spp.n., *E. subspherica* spp.n. (Sporoz. Coccid.). CHRISTENSEN, **66**.
  ECONOMICS.
    COCCIDIOSIS: Coccidiosis in U.S.A. cattle. CHRISTENSEN, **66**.
III. SYSTEMATIC INDEX.
  4. SPOROZOA. (b) COCCIDIIDA.
    Eimeria alabamensis, *E. subspherica* spp.n. (with key to other spp.) from cattle, U.S.A. CHRISTENSEN, **66**.

It should be emphasized that donations to the *Zoological Record* are still quite inadequate, and further support is urgently required from institutions and individuals. EDWARD HINDLE

FORTHCOMING EVENTS

Tuesday, September 2—Tuesday, September 9

WORLD POWER CONFERENCE (at The Hague, Holland).—Conference on "Fuel Economy".

Friday, September 5

INSTITUTE OF ECONOMIC ENGINEERING (at Cowdray Hall, Henrietta Place, London, W.1), at 7 p.m.—Colonel Bernard Ungerson: "Personnel Selection: Army Experience in its relation to the Problems of Industry".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER-IN-CHARGE, CHEMISTRY DEPARTMENT, in the Technical Education Branch of the Department of Public Instruction, Sydney—The Official Secretary, New South Wales Government Offices, 56–57 Strand, London, W.C.2 (September 5).

LECTURER IN PHYSICS—The Secretary, University Offices, 38 North Bailey, Durham (September 6).

ASSISTANT LECTURER IN PHYSICAL GEOGRAPHY, and an ASSISTANT LECTURER IN CHEMISTRY—The Registrar, University College of Wales, Aberystwyth (September 6).

LECTURER IN CHEMISTRY, and a LECTURER IN PHYSIOLOGY—The Principal, Central Technical College, Suffolk Street, Birmingham (September 6).

Assistant Lecturer in Physics in the Bradford Technical College—The Director of Education, Town Hall, Bradford (September 6).

Chair of Comparative Philology at University College—The Academic Registrar, University of London, Senate House, London, W.C.1 (September 10).

Chair of Civil Engineering in the University of Cape Town—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (September 12).

Senior Biochemist at the Teaching and Research Laboratory in the Maudsley Hospital Post-Graduate Medical School—Prof. S. Nevin, Training and Research Laboratory, Maudsley Hospital, Denmark Hill, London, S.E.5 (September 13).

Lecturer in Natural Philosophy in University College, Dundee—The Secretary, The University, St. Andrews (September 13).

Assistant Lecturer in Agricultural Zoology—The Registrar, The University, Leeds 2 (September 15).

Research Fellowship in Medical Physics, and a Lecturer in Town and Country Planning—The Registrar, King's College, Newcastle-upon-Tyne (September 15).

Senior Economist—The Secretary, Agricultural Economics Research Institute, Parks Road, Oxford (September 15).

Lecturer in Geography in the University of Ceylon—The Secretary, Inter-University Council for Higher Education in the Colonies, 8 Park Street, London, W.1 (September 20).

Professor of Anatomy, a Professor of Biochemistry, a Professor of Bacteriology, a Professor of Parasitology, a Professor of Pathology, and a Professor of Social Medicine and Hygiene, in the King Edward VII College of Medicine, Singapore—The Secretary, Inter-University Council for Higher Education in the Colonies, 8 Park Street, London, W.1 (September 20).

Science Graduates with qualifications in Geology and/or Physics, especially Geophysics, for the New Zealand Geological Survey—The High Commissioner for New Zealand, 415 Strand, London, W.C.2 (September 20).

Principal Lecturers, Senior Lecturers, and Lecturers, in Ballistics, Mechanics, Machines, Materials and Structures, Heat Engines, Electrical Engineering, at the Military College of Science, Shrivenham, Wilts—The Secretary, Civil Service Commission, Scientific Adviser's Branch, 27 Grosvenor Square, London, W.1, quoting No. 1965 (September 25).

Research Assistant in the Biochemical Department, and a Statistician to assist in the design of nutritional experiments and undertake analysis of the resulting data—The Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire (September 25).

Safety Officer at the Atomic Energy Research Establishment, Harwell, Didcot, Berks—The Ministry of Labour and National Service, Technical and Scientific Register, Room 171, York House, Kingsway, London, W.C.2, quoting D.239/47A (September 27).

Assistant Electrical Engineer at the Atomic Energy Research Establishment, Harwell, Didcot, Berks—The Ministry of Labour and National Service, Technical and Scientific Register, Room 171, York House, Kingsway, London, W.C.2, quoting D.240/47A (September 27).

Chair of Veterinary Science in the University of Ceylon—The Secretary, Inter-University Council for Higher Education in the Colonies, 8 Park Street, London, W.1 (September 30).

Lecturer in Mathematics at the University of Tasmania—The Agent-General for Tasmania, Golden Cross House, Charing Cross, London, W.C.2 (September 30).

Senior Lecturer in Structural Engineering at Canterbury University College, Christchurch, New Zealand—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (September 30).

Chemists (men and women) of Degree standard for temporary posts in the grades of Senior Scientific Officer, Scientific Officer, Senior Experimental Officer, and Experimental Officer, in the Chemical Inspection Department, Ministry of Supply, for service in North-West England—The Ministry of Labour and National Service, Technical and Scientific Register, Room 171, York House, Kingsway, London, W.C.2, quoting F.694/47A. (September 30).

Director of Radio Research in an enlarged Radio Research Organisation to be established by the Department of Scientific and Industrial Research in extension of its present work in the Radio Division of the National Physical Laboratory and elsewhere—The Secretary, Civil Service Commission, Scientific Adviser's Branch, 27 Grosvenor Square, London, W.1, quoting No. 1967 (September 30).

Lecturer (Grade IIc) in Chemical Engineering, a Research Fellow for fundamental work on the oxidation and constitution of coal, and a Research Scholar for fundamental work on the oxidation and constitution of coal—The Secretary, The University, Edmund Street, Birmingham 3 (October 1).

Regius Professor of Materia Medica and Therapeutics at the University of Glasgow—The Private Secretary, Scottish Office, Fielden House, 10 Great College Street, London, S.W.1 (October 8).

Chair of Chemical Pathology, Senior Assistants (one in Bacteriology and one in Pathology), and a Senior Lecturer in Pathology, in the University of Cape Town—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (October 14).

Professor of Philosophy—The Secretary and Registrar, University College of North Wales, Bangor (October 31).

Senior Lecturer in Horticulture in Canterbury Agricultural College, New Zealand—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (October 31).

Lecturer in Statistics and Economics at the University of Tasmania—The Agent-General for Tasmania, Golden Cross House, Charing Cross, London, W.C.2 (October 31).

Junior Lecturer in Zoology, and a Technician in the Department of Zoology, at the Auckland University College, New Zealand—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (October 31).

Medical Graduates for (*a*) research on the pathology of schistosomiasis in man and experimental animals (mainly abroad), and (*b*) the clinical care of patients at the Field Research Station, Gambia, to undertake nutritional and other investigations—The Secretary, Medical Research Council, 38 Old Queen Street, London, S.W.1.

Senior Laboratory Steward for chemical laboratories—The Bursar, The Alington Hall, The Schools, Shrewsbury.

Research Assistants (2) in the Cytology Department in the Senior Scientific Officer, Scientific Officer and Assistant Experimental Officer grades, and a Librarian (woman) with interest in scientific research—The Director, John Innes Horticultural Institution, Merton, London, S.W.19.

Assistantship in Entomology in the Department of Agricultural and Forest Zoology—The Secretary, The University, Edinburgh.

Research Demonstrator in Botany and Zoology in the Department of Biology—The Registrar, University College, Singleton Park, Swansea.

Physicists to carry out investigations on the physical properties of leather, Chemists to carry out investigations on (*a*) the organic chemistry of the vegetable tannins, (*b*) the processing of leather and elucidation of tannery problems, and a Biologist to work mainly on the micro-biological problems of the industry—The Director of Research, British Leather Manufacturers' Research Association, 1–6 Nelson Square, London, S.E.1.

Laboratory Assistant in the Department of Biochemistry—The Establishment Officer, University College London, Gower Street, London, W.C.1.

Laboratory Assistant to take charge of Chemistry Department—The Bursar, The College, Cheltenham.

Expert in Soap Manufacture, Department of Commerce and Industries, Government of Ceylon—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.N.17602.

Laboratory Technician (Grade B) with general experience in clinical pathology, at St. Margaret's Hospital, Stratton St. Margaret, Swindon—The County Medical Officer, County Hall, Trowbridge, Wilts.

Lecturer in Radio Engineering—The Clerk, Northern Polytechnic, Holloway, London, N.7.

Sir Jesse Boot Chair of Chemistry—The Registrar, University College, Nottingham.

Graduate Lecturer in Mechanical Engineering Subjects at the Lincoln Technical College—The Director of Education and Clerk to the Governors, City Education Offices, 4 Lindum Road, Lincoln.

Senior Lecturer in Education in the University of Otago, Dunedin—The High Commissioner for New Zealand, 415 Strand, London, W.C.2.

NATIONAL PARKS

IN 1872 the first national park in the world, the Yellowstone National Park, was established by an Act of Congress, and it is still the most noted of all American national parks. It lies mainly in the State of Wyoming and is sixty-two miles long and fifty-four miles wide. The scenery in this park is of exceptional grandeur and beauty, and the park contains many natural features of outstanding interest —forests, alpine flora, a very varied terrestrial and aquatic fauna, more than a hundred geysers and four thousand hot springs, and the Grand Canyon of the Yellowstone. It can be no cause for wonder, therefore, that such a unique area should have been taken over for the enjoyment of all almost as soon as it was first surveyed. Since then, as stated by Dr. Herbert Smith in his article on "Nature Protection in Great Britain" (p. 457 of this issue), the idea of national parks has spread throughout the world and in many places been put into effect. Some, such as that in the Belgian Congo, are very extensive ; others are comparatively small.

But national parks need not necessarily be confined to areas of exceptional merit or interest ; moreover, as pointed out in Dr. Smith's article, the *raison d'être* of a national park is not simply public pleasure or scientific study ; it must perform a multiple function. This casts our minds back to December 8, 1938, when the Linnean Society of London met to discuss the objects of national parks. The discussion arose from a letter sent by Prof. J. B. Cleland, chairman of the Commissioners of the National Park at Belair, South Australia, who asked the Society for a definition of a national park, and to express an opinion as to how far facilities for sport and recreation should be allowed to replace the original fauna and flora, especially when the park is near a thickly populated area.

At that Linnean Society discussion, Sir Peter Chalmers Mitchell claimed that a national park should be an area under public control where wild animal and plant life is preserved and hunting and collecting only allowed under licence ; but he also agreed that it would be unreasonable to hand over smaller parks near towns for the exclusive use of naturalists. Dr. Julian Huxley maintained that, at any rate in Great Britain, within a national park, recreation, walking and camping in unspoilt countryside must take precedence over the preservation of flora and fauna. Dr. Herbert Smith himself suggested that the two main aims of national parks—scientific and recreational—are not incompatible. Other views expressed at that discussion tended to support the idea that, under intelligent control, a national park could be a sanctuary where plants and animals could thrive under natural conditions (though it must be borne in mind that these conditions are dynamic, not static), yet also afford facilities for recreation and sport even if these may have to be limited to certain well-defined areas within the park.

Apart from their multiple functions, national parks will vary, of course, according to their individual characters. Though the Linnean Society's discussion was held nine years ago, the idea of the establishment of national parks in Britain has gained ground and several important reports have been published since. These are discussed by Dr. Herbert Smith in the article published in this issue.

It is well that in a small country such as Britain the conception of the form and function of national parks should be thoroughly discussed before any large-scale plans are formulated and then put into effect. As Dr. Smith points out, Britain has a beautiful landscape varying considerably in character; in fact, the variation itself is worthy of note. So to preserve this for posterity the establishment of national parks is essential. In the discussions and reports so far published, Nature preservation and respect for geological monuments loom large; but in the latest report, that of the National Parks Committee of the Ministry of Town and Country Planning recently published, it is emphasized that the function of national parks should be "more the spiritual and bodily refreshment of the people, especially the inhabitants of cities and towns, than the protection of wild life". Furthermore, considerable tact and caution are necessary when deciding what priority or privileges should be given to *bona fide* students of natural history over the general lay public. For example, complaint has already appeared in the newspaper press about the closing of Flatford Mill (immortalized by Constable) to the general public in favour of students. No matter what facts lie behind the acquisition of any monument, it is desirable that public opinion be taken into full consideration before final policy is settled, especially since it seems to be agreed that spiritual and bodily refreshment of the general public is of paramount importance. In other words, the authorities who have the final say in choosing and administering national parks should aim at preventing different interests from becoming clashing interests and so conflicting with each other. On the contrary, they should aim at utilizing such parks as places where not only may each interest be satisfied so far as is commensurate with the common weal, but also where one interest can meet the other to the benefit of both—a symbiosis of interests.

Thus might become established that nucleus of biological service, as Dr. Smith envisages and Dr. E. Hindle in his presidential address to Section D (Zoology) of the British Association meeting at Dundee this year pleaded for, which would offer the best field opportunities for the natural historian working among the lay public, who would conceivably watch his work with interest. Here would be an arena where work and play could move together hand in hand.

Difference in character must also be taken into account. A park in the Scottish Highlands would be unlike one in the Lake District, and again very different from one on the rolling downs of the south of England. This would need serious consideration when deciding on organisation and personnel for administration and control.

SCIENTIFIC AND TECHNICAL BOOKS

As one of the measures for reducing British expenditure in countries in the 'dollar area', it has been announced that restrictions are being imposed on the importation into Britain of books. At a time when emphasis is being placed increasingly on the importance of international understanding, it is most unfortunate that this particular medium should have been selected as a means of effecting economies; books are surely one of the best means of making one people acquainted with another. Here we are concerned mainly with scientific and technical books, and the restriction will in practice apply chiefly, though not entirely, to American books. The position is that scientific and technical books may no longer be imported except under individual licence. British publishers have to submit to the licensing authorities evidence of the value of their pre-war imports of such books, and they will be given a licence to import foreign books to the same annual value. Thus we return, at a stroke, to the maximum war-time restrictions. Publishers will now have to apply quarterly for licences to import specified quantities of named books, and giving in each case the name of the exporting country.

There are some observations on such a scheme which immediately come to mind. First there is the vexatious delay in obtaining a necessary book, should the British publisher have no copy in stock. Further, in imposing this form of individual licence, the Government is in effect instituting a system which might easily become a form of censorship. A more immediate objection is that the present scheme is based on money value, and takes no account of the increase in book production costs. So far as American books are concerned, prices are 50 per cent and more above the pre-war figure for corresponding books. In effect, therefore, the number of scientific and technical books of American origin it will be possible to import into Britain will be substantially less than the figure for 1939.

It is becoming generally accepted that the utmost efficiency is necessary in the scientific and technical fields to enable Britain to recover its position in the world. Yet by cutting down supplies of the essential books, the Government is putting an important obstacle in the path; and this at a time when there is an acute shortage of school and university text-books and also of standard works of reference. It may be urged that some American text-books are not suited for the courses in British schools and universities, but that argument cannot be applied to research monographs and reference works; these, with the all-important specialist periodicals, are essential tools for the scientific worker trying to keep abreast of modern developments.

While it must be granted that restrictions on general expenditure are necessary, it would seem that scientific and technical books should have a high priority in the permissible expenditure of dollars; and it should be possible to devise a scheme whereby such books are made more readily available.

DUTCH PIONEERS IN SCIENCE AND INDUSTRY

Nederlandsche Baanbrekers der Wetenschap
Door J. C. Alders. Pp. 201. (Amsterdam: Bigot and Van Rossum N.V., n.d.) n.p.

THIS book contains excellent popular descriptions of the work of the Dutch pioneers of science and industry during the last fifty years. The sciences included in this book are astronomy, biology, chemistry and physics, and the industries agriculture, aviation, mineral oil, radio and tin. The book is really about the subjects mentioned, but it is arranged biographically. Of the many famous names mentioned, which include Nobel Prize winners, are the following: Kamerlingh Onnes, Van der Waals, Lorentz, Zeeman, Debye, de Vries, Fokker; and reference is made to the Philips laboratory at Eindhoven.

It was in 1895 that Zeeman discovered that in a plane parallel to an intense magnetic field each line of the spectrum of a sodium or lithium flame placed in the field became a doublet, whereas if the light was examined spectroscopically in a direction at right angles to the field, there was each ordinary line together with two components associated with it. When a spectroscope is pointed to the sun's centre, doublets are seen; whereas triplets appear if a sensitive spectroscope is directed at a point near the sun's periphery. Thus is demonstrated the sun's intense radial magnetic field. This work and other like it has led to the recent hypothesis of Blackett.

Van't Hoff was a pioneer in the mechanical theory of valency and in the connexion of the optical activity of many carbon compounds with their chemical constitution. The theorem known by his name connects the quantitative displacement of equilibrium with change of temperature, and he showed the analogy between dilute solutions and gases via their osmotic pressures.

De Vries was perhaps unlucky in his choice of the evening primrose (*Œnothera lamarckiana*) for his work on mutations in heredity and evolution, when he put forward his ideas of spurts or storms of mutation—because some of the changes from individual to individual have no evolutionary significance, since the supposedly new species and variations cannot breed true. The revived work of Mendel and later work on chromosomes have superseded the work of de Vries.

Vening Meinesz is particularly famous for gravity measurements at sea in a submarine. Between the years 1922 when the first test of Meinesz's two pendulums was carried out on S.S. *Paleleh* between Ymuiden and Flushing, and 1934 when he made a submarine trip via the Cape to the Dutch East Indies, Vening Meinesz was constantly engaged in improving his apparatus, testing it at sea, and working up the results obtained. During 1926–27 he undertook a voyage from Holland via Panama to Soerabaya, in 1929–30 to the Gulf of Mexico and to the Dutch East Indies, and in 1932 to the Azores and Cuba. In the Dutch East Indies, he made numerous gravity measurements and discovered an 'axis' where gravity is greater than expected, in some places by 65 milligalls. Next to this is a chain of gravity deficiencies, which chain runs through Sumatra, south of Java, across the Soenda Islands, through the Philippine Islands to Japan. This chain of approximately 100 km. width runs along with, or parallel to, the earthquake belt. In the Dutch East Indies volcanoes are on the landward side of the axis of Vening Meinesz. This axis is very significant in the realm of geophysics.

In the world of industry the Dutch have made great strides in our methods of working tin and oil; the work of Fokker in aeronautics and the laboratory of the Philips Co. are too well known to require enlarging upon here. Less well known, though no less important particularly at the present time, is the work of the Dutch Cultivation Co. and the Dutch potato flour industry.

From what has been described above it will be seen that this popularly written book will be of great value in putting before the general Dutch public and the world the contributions which her learned and industrious sons have made to Holland and the world, and will show that this is indeed great when one looks at the size and character of the countryside. The book is in Dutch, and the author of this notice is indebted to Mr. C. Knor for assistance with the translation. ERNEST TILLOTSON

THE U.S. PHARMACOPŒIA

The Pharmacopœia of the United States of America (the United States Pharmacopœia)
Thirteenth revision. By Authority of the United States Pharmacopœial Convention. Pp. cvii + 957. (Easton, Pa.: Mack Publishing Co., 1947.)

THE first United States Pharmacopœia appeared in 1820, and up to 1936 revisions appeared at intervals of about ten years. This interval has now been reduced to five years, owing to the rapid advance of therapeutics. The thirteenth revision (1947) is an impressive book containing more than a thousand pages, and much work has been put into its preparation. It is controlled by the U.S. Pharmacopœial Convention, which meets "upon the second Tuesday in May in the first year in each decade ending in zero". The number of delegates attending the convention in 1940 was 487, not counting guests from various neighbouring countries, of which Costa Rica, Cuba, Dominican Republic, Nicaragua, Panama and Uruguay have given official status to this Pharmacopœia. This convention elects a president, five vice-presidents, a secretary, an assistant secretary, a treasurer, a board of trustees and a general committee of revision consisting of sixty members. The board of trustees elects a director of pharmacopœial revision, and the general committee provides ten sub-committees, the chairmen of which constitute the executive committee of revision. These details and many more are given in the introductory pages of the Pharmacopœia.

The complex organism thus sketched is rich, partly because much of the work is unpaid and carried out from a sense of public duty. It is unfortunate that a good deal of it is duplicated in other countries in order to produce many other pharmacopœias suited to local conditions. The time is surely coming when an international pharmacopœia will be accepted all over the world. Some steps in this direction have been made; but progress is slow. An organisation such as the Americans have provided might produce a truly international pharmacopœia, though, unfortunately, most other countries are afraid of being swamped. The advantages of internationalization in this field are, however, so great that every effort should be made in this direction. One difficulty lies in the fact that the trend of therapeutic practice differs in different countries. It seems strange that the

Americans are at this moment removing 'Pamaquine' and chaulmoogra oil from their Pharmacopœia. They do not include leptazol, or nikethamide, or lobeline, and seem to rely on picrotoxin as the only official analeptic. They include no acridine antiseptic.

Another difficulty is the question of nomenclature. New pharmacopœias generally contain a few new names for old drugs and omit the old names, which are unsuitable for official use for one reason or another. Sometimes these new names explain themselves; benzalkonium is fairly obviously a cationic detergent. Sometimes their interpretation forms a test of general knowledge. Iodopyracet is the new American name for diodone, which is used to display the renal pelvis under X-rays. Some readers will no doubt be driven to other works of reference to confirm the fact that these two substances are, in fact, identical.

Some attempt is made to achieve agreement about such neologisms between the British and the Americans, but the results are disappointing. The Americans use 'f' where the British use 'ph', and simplify spelling in various other ways. The drugs known in America as epinephrine, menadione, tetracaine, quinacrine, and anhydrohydroxyprogesterone are known in Britain as adrenaline, menaphthone, amethocaine, mepacrine and ethisterone respectively.

The new work contains many admirable features. The official names have been chosen so as to bring allied preparations together in the alphabetical arrangement; for example, tincture of opium is called opium tincture, so that it comes near opium itself. Metric doses have precedence over avoirdupois; this convention will be welcomed internationally. English names have precedence over Latin names; this convention will be welcomed in English-speaking countries. There is much incidental information about the properties of a wide range of substances which are only occasionally used by pharmacists as reagents, and about the measurement of viscosity, *p*H, turbidity, melting points, optical relation, etc.

Methods of biological assay are described for such substances as epinephrine, posterior pituitary, insulin, vitamins A, B and D, and all preparations containing cardiac glycosides, and there are microbiological methods for nicotinamide and riboflavin. Such biological methods are not applied to pure active principles such as epinephrine or ouabain, but they are applied to preparations of these active principles, such as epinephrine solution or ouabain injection. In these cases, the assay is clearly not intended to be applied to each sample, but only used in cases of doubt or dispute. In the case of other drugs, such as insulin and digitalis tincture, the assay forms an integral part of the manufacture, and the exact procedure is prescribed in great detail, which leaves much less to the discretion of the individual than is the custom in Britain. Some of the details of the techniques will no doubt be criticized. Cats are to be used for the assay of digitalis, and methods using frogs are not recognized. There is no convincing evidence to justify this decision. Rabbits, and not mice, are to be used for the assay of insulin, and they must receive three doses of the unknown preparation and one dose of the standard, instead of two doses of each, as is customary here. The attempt to make these tests foolproof has made them too rigid.

The assays of various vitamins are not designed to measure their concentration, but only to ensure a certain minimum activity. This decision greatly simplifies the interpretation of the result. The standard preparations to be used for these assays are distributed officially; the Pharmacopœia seems to contain no information about their composition. It would be interesting to have been told whether the standard for vitamin D in cod liver oil is vitamin D_3, as it ideally should be, or calciferol.

For various reasons, some of which are mentioned above, this Pharmacopœia could not be officially adopted as it stands in Great Britain, but it contains much that we can admire, and might copy. The Americans are to be congratulated on a fine piece of work.

J. H. Gaddum

METHODS IN CELLULOSE CHEMISTRY

The Methods of Cellulose Chemistry

Including Methods for the Investigation of Substances associated with Cellulose in Plant Tissues. By Dr. Charles Dorée. Second edition, revised and enlarged. Pp. xii+543. (London: Chapman and Hall, Ltd., 1947). 42*s*. net.

THE earlier edition of this book has been of very great value to all whose interests have been in the field of cellulose chemistry, and there can be no doubt, therefore, of the welcome which will be accorded to a second edition. The full usefulness of the volume can be appreciated only when the complete title is considered, since the reader will find, in addition to the multifarious methods of investigation applicable to cellulose and its derivatives, concise accounts of the methods of attack which have been developed for investigations on lignin, hemi-celluloses and pectic materials.

Much has been added to our knowledge of all these substances in the course of the fifteen years which have elapsed since the first edition was published, and Dr. Dorée has now undertaken with conspicuous success the formidable task of incorporating new matter and revising the old. No fundamental changes have been found necessary, but a great deal of new material now finds its place in the book. In Part I methods used in the examination of normal cellulose are collected, including the measurement of physical properties, methods of analysis applicable to cellulose, mercerized cotton, rayons, hydrocelluloses and oxycelluloses. There is a chapter devoted to the investigation of damage in cotton and linen fabrics. The second part is concerned with synthetic derivatives of cellulose, including esters and ethers, and on this topic much new matter has been added in the present edition. The third part deals with the compound celluloses, and in addition to a chapter on the qualitative and quantitative examination of plant tissues there are detailed accounts of procedures for the estimation of cellulose and lignin, and of the standard methods for the estimation of furfural, uronic acid and methoxyl. Chapters are included also on the analysis of wood, and on the chemistry of lignin and the hemi-celluloses.

The book is designed for use by the practical worker in the laboratory. It is well illustrated with figures and graphs and is fully documented. Precise and detailed directions are given for all the analytical procedures. The comprehensive author- and subject-indexes facilitate reference, and the book has been excellently produced in a clear type which is a pleasure to read. Dr. Dorée is to be warmly congratulated on the appearance of this second edition of a most useful and valuable work.

E. L. Hirst

PEACEFUL APPLICATIONS OF NUCLEAR FISSION

A SYMPOSIUM on the "Peaceful Applications of Nuclear Fission" was arranged by Section A (Mathematics and Physics) at the recent meeting of the British Association at Dundee. It was opened by the president of the Section, Sir Edward Appleton, who said that no scientific subject had ever aroused quite the same mixture of hopes and fears. At that meeting they were to concentrate on the hopes; in due course the work conducted on the development of the atomic bomb would lead to the saving of far more lives than were lost in the attacks on Japan.

Dr. J. D. Cockcroft remarked that the peace-time applications of nuclear fission would result from the achievement of a divergent nuclear chain reaction in the atomic pile—first built by Prof. E. Fermi in the University of Chicago in 1942. The fission pile provides a much more powerful source of neutrons than the largest cyclotron. The pile would make possible new types of experiments in nuclear physics and would be the main source of radioactive isotopes. With the production of neutrons goes the development of heat, and the pile is a *potential* though not certain new source of power for the world.

The first objective of the Atomic Energy Research Establishment at Harwell, Berks, had been the construction of a low-power graphite pile known as "G.L.E.E.P." similar to that now in use at the Argonne National Laboratory in Chicago. This pile consists of several hundred tons of graphite bricks between which are grooves for the insertion of uranium metal and uranium oxide. Surrounding the pile is a shield of concrete about 5 ft. in thickness. This is required to reduce the intensity of the neutron and gamma radiation developed inside the pile to tolerance-levels. The shield is pierced with holes for control instruments, control rods, safety rods and for 'thermal columns' to bring neutrons of thermal energy out to the shield face for experiments.

The concrete shield and its accessories took about a year to build. Loading of the uranium started on August 5 and was completed by August 15 of this year. During the loading of the uranium the multiplication constant, k, of the pile increased towards unity, and since one neutron released in the spontaneous fission of a U238 nucleus leads to $1 + k + k^2$ or $1/(1 - k)$ neutrons, the course of approach to the critical or divergent state is followed by recording by a boron trifluoride-filled counter the flux of neutrons inside the pile. Thus on August 7, when 7 tons of uranium had been loaded, the counter recorded 17 neutrons per minute. By August 11 this had increased to 55 neutrons/minute, by the morning of August 15 to 2,400 and by early afternoon to 6,600 per minute. At this point the counter was saturated—the pile being almost divergent. During the last stages of loading, the control rods were partially inserted, reducing k slightly. Uranium was then loaded until the divergent point was just passed. At this stage the pile generated about 0·1 watt of thermal energy. The power-level increases exponentially with time but with a very long period. The period depends on $1/(k - 1)$, and with an excess of k of 1/40,000 the period is one hour. The pile is therefore very easy to control. A withdrawal of the control rods led to a decrease of the period to about a minute and the power-level was allowed to increase to 100 watts, at which level ionization chambers had been pre-set to release the shut-off rods and shut down the pile. The first objective of the Harwell work had, therefore, been realized in about fifteen months.

Measurements would now be carried out to determine all the pile characteristics. This was expected to take about one month. After that the power-level would be increased to a level set by the safe operating temperature of the uranium. In this pile only very simple cooling is used, and it would probably be necessary to limit the average power to about 50 kilowatts. At this power-level there would be a maximum thermal neutron flux of 10^{10} neutrons/sq.cm./sec.; the total number of neutrons generated would be about 3×10^{15} per sec., of which about one per cent could be used for production of radioactive isotopes or for experimental work. It was intended to start radioactive isotope production immediately. Some isotopes could be produced in adequate intensities by this pile—thus it is estimated that 5–10 curies per month of radiophosphorus could be produced monthly by the capture of neutrons in phosphorus. Production of high specific activity P^{32} by the (n,p) reaction in sulphur would be considerably smaller. Long-lived isotopes such as C^{14} could only be produced in small quantities, and adequate production would have to await the completion of the second Harwell pile.

One of the principal applications of the low-power pile is the study of the nuclear reactions of elements with slow neutrons. The introduction of as little as 0·1 mgm. of cadmium into the pile produces a detectable change of power-level; and from the rate of change, the absorption cross-section for slow neutrons can be determined. In practice, specimens under investigation are moved into and out of the pile with a period of 20 sec. or so and the amplitude of oscillation of the power-level measured by a resonant galvanometer or other suitable methods. A pile of this type is an indispensable tool for the control of nuclear properties of all basic materials used in the construction of piles.

The power-level of a pile can be increased by more intensive cooling of the uranium metal, and in the second Harwell pile the metal rods will be cooled by a high-speed stream of air flowing past the rods. In this way the power-level could be increased to several thousand kilowatts. The uranium metal would be sheathed with aluminium to prevent oxidation and escape of fission products. The decreasing creep strength of aluminium with increasing temperature would probably limit surface temperatures to about 350° C., and emergent gas temperatures would therefore be limited to about 300° C. Although this is not high enough for efficient power production, a heat exchanger would be placed in the emerging gas stream and some use made of the pile heat.

The emergent gas temperature could be increased if a material having more favourable properties could be substituted for aluminium. Metals such as steel would reduce the multiplication constant below unity; beryllium would be suitable if it could be produced in ductile form.

The second Harwell pile will be used to study problems of power production. Thus it is important to study the effect of neutron irradiation on the physical properties of materials used in piles—it is known that some deterioration takes place. It is also important to study the effect of formation of fission products on the multiplication constant of the pile, and in particular the effect of the partial substitution of U235 by plutonium in the pile.

It is expected that the neutron flux and available neutrons will be of the order of a hundred times that available in the G.L.E.E.P. This would make possible the full production of most radioactive isotopes required in Britain. A few isotopes would be limited in quantity.

This pile would also provide a powerful source of fission products—which are distributed among the thirty-five elements from zinc to gadolinium. At 1,000 kW. power-level, about a gram a day of fission products would be produced.

Other types of pile important for scientific research include the heavy-water piles. These piles have a higher multiplication constant than the graphite pile, and would use a substantially smaller amount of uranium and moderator. For a fixed power output they could give a much higher neutron flux, and this is very important for some experiments and for the study of future developments. A high-power heavy-water pile has recently been completed at Chalk River by the Canadian National Research Council, and will provide an important experimental tool for atomic energy research.

The future of the application of nuclear fission to the large-scale development of power is at present obscured by lack of information on a number of essential points.

A pile using natural uranium sheathed by aluminium and cooled by a circulating gas could be used for steam generation and power production by a steam turbine. Experimental plants of this type would probably be built, though their thermodynamic efficiency would be low, due to the temperature limit of aluminium. If Nature were exceptionally kind, a plant of this kind containing 100 tons of uranium would generate 100,000 kW. of thermal energy for twenty years without fuel replacement. Actually, however, the formation of fission products will probably lead to poisoning of the chain reaction due to their additional absorption, and difficulties may be experienced due to deterioration of materials under the intense neutron bombardment of the pile. The metal will, therefore, have to be withdrawn at frequent intervals, the fission products extracted and the uranium and plutonium reprocessed. Until operating experience tells us how frequently this will have to be done, and what the costs will be, it is not possible to predict the costs of nuclear power. The position about reserves of nuclear fuel is equally uncertain at the present time, since the proportion of the uranium which can be used is unknown.

So far, piles have used only a fraction of the energy of U235. In the future, we may hope to do considerably better than this. As a pile burns up the primary fuel atoms of U235, the neutrons released in the fission can turn U238 into plutonium, which is fissionable by slow neutrons and is a secondary fuel just as good as U235. One U235 atom will in general be replaced by rather less than one plutonium atom; this in turn will be partially replaced. The overall result is that there is a possibility of utilizing more than the fission energy of U235. Ideally we might go a long way towards reaching the full utilization of U238—how far we can go we do not know.

There is also a possibility of utilizing the fission energy of thorium by turning it into U233, which is also fissionable by slow neutrons.

One other major uncertainty stands in the way. With nuclear power goes a very large-scale production of radioactive materials. A power plant generating the thermal energy of a million kilowatts produces daily an activity of the order of a million curies even after an appreciable decay is allowed for. A world run on nuclear power would generate at least a hundred times this activity. The safe disposal of these products presents a major problem.

Prof. O. R. Frisch described the application of the fission pile to nuclear research. A high-power pile of the type being built at Harwell would produce very large numbers of fast and slow neutrons. Experiments requiring fast neutrons continue to be carried out, for the most part, on cyclotrons, which provide a point source of fast neutrons, whereas the pile neutrons are spread out over several thousand cubic feet of pile volume. The pile has, however, a decisive advantage for experiments with slow neutrons, since the cyclotron source becomes diffuse in slowing down the neutrons. Experimental work was described using a mechanical velocity selector to study the velocity distribution of slow neutrons emerging from the pile. Filtering through graphite has been shown to reduce their mean velocity by a factor of 4 owing to their wave properties leading to selective transmission through the graphite lattice. This is due to the absence, for very slow neutrons, of lattice planes fulfilling the Bragg reflexion condition. On the other hand, homogeneous neutron beams can be obtained by Bragg reflexion from crystals, and the crystal spectrometer provides a powerful method of studying neutron-capture phenomena. It is expected also that neutron scattering from hydrogen atoms in crystals may result in neutron spectroscopy being a valuable tool for the organic chemist. Slow neutrons have been shown to be totally reflected at glancing angles; this proves that the refractive index of the materials used (glass, graphite, etc.) is less than unity for neutron waves. The intense beam of pile neutrons would make it worth while to look for the decay of the neutron into a proton and an electron.

Mr. W. G. Marley described the production of radioactive isotopes in a pile. The simplest procedure is to produce them by neutron capture, that is, by (n,γ) reactions. The materials to be irradiated are placed in the reflector of the pile, where up to one-fortieth of the pile neutrons can be absorbed for this purpose.

Some biological experiments require a high specific activity—500 millicuries per gram of materials. For this purpose it might be necessary to use (n,p) reactions, for example, in $S^{32}(n,p)P^{32}$. Many of these reactions require fast neutrons and can only be produced in the core of the pile, where the available neutrons will be only about one-tenth of those available in the reflector. A few isotopes such as tritium would be produced by (n,α) reactions. The high-power Harwell pile would be able to produce quantities of most isotopes more than adequate for all likely requirements. A few long-lived isotopes such as tritium, C14, Cl37, would be limited by pile capacity, though an annual production of 4–5 curies of C14 should be possible.

It is expected that a few radioactive isotopes, such as Na22, will still have to be produced in the cyclotron, since they can only be produced by neutrons by $(n, 2n)$ reactions requiring very fast neutrons.

Radioactive isotopes produced by (n,p) reactions would require chemical separation; and when the processes have been established at the Harwell station, routine separation will be carried out by the Radiochemical Centre of the Ministry of Supply. The allocation of radioactive isotopes will be carried out by a sub-committee of the Advisory Council for the Radiochemical Centre. This sub-committee, under the chairmanship of Dr. J. D. Cockcroft, includes representatives of user interests—the Medical and Agricultural Research Councils and the Department of Scientific and Industrial Research, which will represent the universities and industry.

Radioactive isotopes from piles in the United States have been available to American users only since 1946, and a large number of applications to medical, biological and industrial research have already been found, while the future has been declared by Dr. G. Seaborg to hold unlimited possibilities.

J. D. COCKCROFT

OBSERVATIONS ON THE TRACKS OF SLOW MESONS IN PHOTOGRAPHIC EMULSIONS*

By C. M. G. LATTES, DR. G. P. S. OCCHIALINI and DR. C. F. POWELL

H. H. Wills Physical Laboratory, University of Bristol

INTRODUCTION. In recent experiments, it has been shown that charged mesons, brought to rest in photographic emulsions, sometimes lead to the production of secondary mesons. We have now extended these observations by examining plates exposed in the Bolivian Andes at a height of 5,500 m., and have found, in all, forty examples of the process leading to the production of secondary mesons. In eleven of these, the secondary particle is brought to rest in the emulsion so that its range can be determined. In Part 1 of this article, the measurements made on these tracks are described, and it is shown that they provide evidence for the existence of mesons of different mass. In Part 2, we present further evidence on the production of mesons, which allows us to show that many of the observed mesons are locally generated in the 'explosive' disintegration of nuclei, and to discuss the relationship of the different types of mesons observed in photographic plates to the penetrating component of the cosmic radiation investigated in experiments with Wilson chambers and counters.

Part I. Existence of Mesons of Different Mass

As in the previous communications[1], we refer to any particle with a mass intermediate between that of a proton and an electron as a meson. It may be emphasized that, in using this term, we do not imply that the corresponding particle necessarily has a strong interaction with nucleons, or that it is closely associated with the forces responsible for the cohesion of nuclei.

We have now observed a total of 644 meson tracks which end in the emulsion of our plates. 451 of these were found, in plates of various types, exposed at an altitude of 2,800 m. at the Observatory of the Pic du Midi, in the Pyrenees; and 193 in similar plates exposed at 5,500 m. at Chacaltaya in the Bolivian Andes. The 451 tracks in the plates exposed at an altitude of 2,800 m. were observed in the examination of 5 c.c. emulsion. This corresponds to the arrival of about 1·5 mesons per c.c. per day, a figure which represents a lower limit, for the tracks of some mesons may be lost through fading, and through failure to observe tracks of very short range. The true number will thus be somewhat higher. In any event, the value is of the same order of magnitude as that we should expect to observe in delayed coincidence experiments at a height of 2,800 m., basing our estimates on the observations obtained in similar experiments at sea-level, and making reasonable assumptions about the increase in the number of slow mesons with altitude. It is therefore certain that the mesons we observe are a common constituent of the cosmic radiation.

Photomicrographs of two of the new examples of secondary mesons, Nos. III and IV, are shown in Figs. 1 and 2. Table 1 gives details of the characteristics of all events of this type observed up to the time of writing, in which the secondary particle comes to the end of its range in the emulsion.

TABLE 1

Event No.	Range in emulsion in microns of Primary meson	 Secondary meson
I	133	613
II	84	565
III	1040	621
IV	133	591
V	117	638
VI	49	595
VII	460	616
VIII	900	610
IX	239	666
X	256	637
XI	81	590

Mean range 614 ± 8 μ. Straggling coefficient $\sqrt{\Sigma\Delta_i^2/n} = 4\cdot3$ per cent, where $\Delta_i = R_i - \bar{R}$, R_i being the range of a secondary meson, and $\bar{R}$ the mean value for n particles of this type.

The distribution in range of the secondary particles is shown in Fig. 3. The values refer to the lengths of the projections of the actual trajectories of the particles on a plane parallel to the surface of the emulsion. The true ranges cannot, however, be very different from the values given, for each track is inclined at only a small angle to the plane of the emulsion over the greater part of its length. In addition to the results for the secondary mesons which stop in the emulsion, and which are represented in Fig. 3 by black squares, the length of a number of tracks from the same process, which pass out of the emulsion when near the end of their range, are represented by open squares.

The μ-Decay of Mesons

Two important conclusions follow from these measurements. Our observations show that the directions of ejection of the secondary mesons are orientated at random. We can therefore calculate the probability that the trajectory of a secondary

---

* This article contains a summary of the main features of a number of lectures given, one at Manchester on June 18 and four at the Conference on Cosmic Rays and Nuclear Physics, organised by Prof. W. Heitler, at the Dublin Institute of Advanced Studies, July 5-12. A complete account of the observations, and of the conclusions which follow from them, will be published elsewhere.

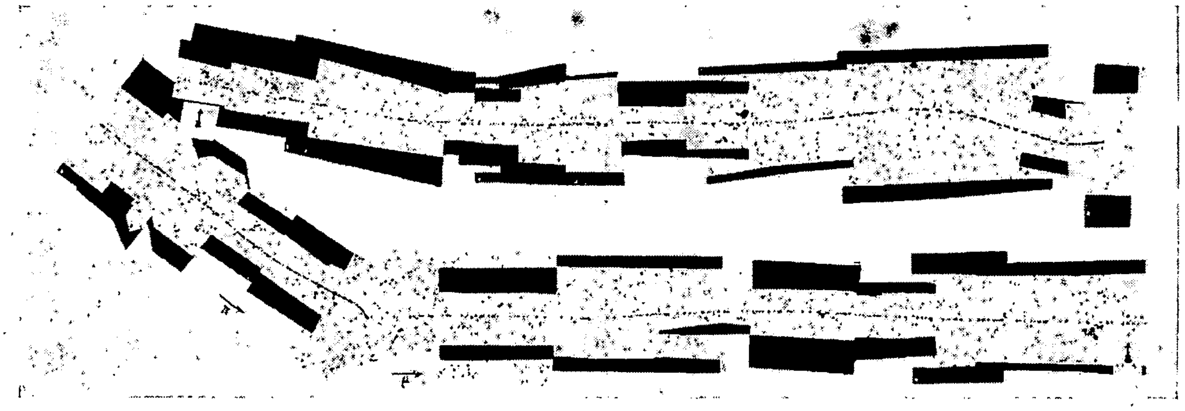

Fig. 1. OBSERVATION BY MRS. I. POWELL. COOKE × 95 ACHROMATIC OBJECTIVE; C2 ILFORD NUCLEAR RESEARCH EMULSION LOADED WITH BORON. THE TRACK OF THE μ-MESON IS GIVEN IN TWO PARTS, THE POINT OF JUNCTION BEING INDICATED BY a AND AN ARROW

meson, produced in a process of the type which we observe, will remain within the emulsion, of thickness 50 μ, for a distance greater than 500 μ. If we assume, as a first approximation, that the trajectories are rectilinear, we obtain a value for the probability of 1 in 20. The marked Coulomb scattering of mesons in the Nuclear Research emulsions will, in fact, increase the probability of 'escape'. The six events which we observe in plates exposed at 2,800 m., in which the secondary particle remains in the emulsion for a distance greater than 500 μ, therefore correspond to the occurrence in the emulsion of 120 ± 50 events of this particular type. Our observations, therefore, prove that the production of a secondary meson is a common mode of decay of a considerable fraction of those mesons which come to the end of their range in the emulsion.

Second, there is remarkable consistency between the values of the range of the secondary mesons, the variation among the individual values being similar to that to be expected from 'straggling', if the particles are always ejected with the same velocity. We can therefore conclude that the secondary mesons are all of the same mass and that they are emitted with constant kinetic energy.

If mesons of lower range are sometimes emitted in an alternative type of process, they must occur much less frequently than those which we have observed; for the geometrical conditions, and the greater average grain-density in the tracks, would provide much more favourable conditions for their detection. In fact, we have found no such mesons of shorter range. We cannot, however, be certain that mesons of greater range are not sometimes produced. Both the lower ionization in the beginning of the trajectory, and the even more unfavourable conditions of detection associated with the greater lengths of the tracks, would make such a group, or groups, difficult to observe. Because of the large fraction of the mesons which, as we have seen, can be attributed to the observed process, it is reasonable to assume that alternative modes of decay, if they exist, are much less frequent than that which we have observed. There is, therefore, good evidence for the production of a single homogeneous group of secondary mesons, constant in mass and kinetic energy. This strongly suggests a fundamental process, and not one involving an interaction of a primary meson with a particular type of nucleus in the emulsion. It is convenient to refer to this process

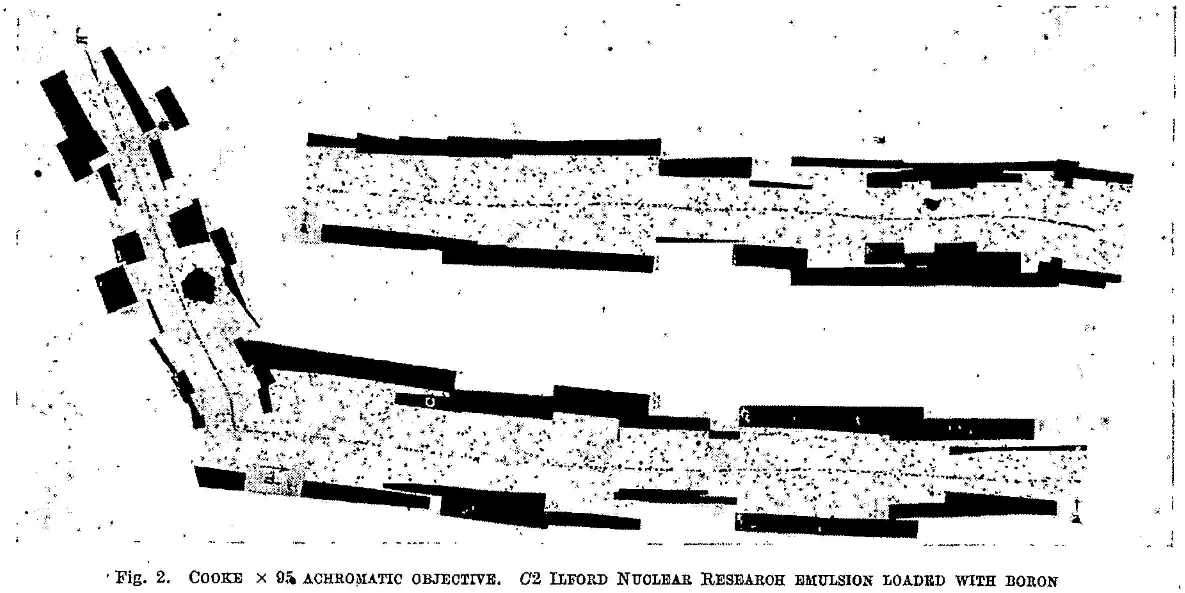

Fig. 2. COOKE × 95 ACHROMATIC OBJECTIVE. C2 ILFORD NUCLEAR RESEARCH EMULSION LOADED WITH BORON

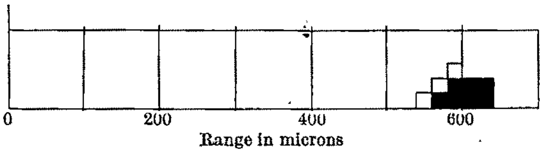

Fig. 3. DISTRIBUTION IN RANGE OF TEN SECONDARY MESONS. THOSE MARKED ■ STOP IN THE EMULSION; THE THREE MARKED □ LEAVE THE EMULSION WHEN NEAR THE END OF THEIR RANGE. MEAN RANGE OF SECONDARY MESONS, 606 MICRONS. THE RESULTS FOR EVENTS NOS. VIII TO XI ARE NOT INCLUDED IN THE FIGURE

in what follows as the μ-decay. We represent the primary mesons by the symbol π, and the secondary by μ. Up to the present, we have no evidence from which to deduce the sign of the electric charge of these particles. In every case in which they have been observed to come to the end of their range in the emulsion, the particles appear to stop without entering nuclei to produce disintegrations with the emission of heavy particles.

Knowing the range-energy relation for protons in the emulsion, the energy of ejection of the secondary mesons can be deduced from their observed range, if a value of the mass of the particles is assumed. The values thus calculated for various masses are shown in Table 2.

TABLE 2

Mass in m_e	100	150	200	250	300
Energy in MeV.	3·0	3·6	4·1	4·5	4·85

No established range-energy relation is available for protons of energies above 13 MeV., and it has therefore been necessary to rely on an extrapolation of the relation established for low energies. We estimate that the energies given in Table 2 are correct to within 10 per cent.

Evidence of a Difference in Mass of π- and μ-Mesons

It has been pointed out[1] that it is difficult to account for the μ-decay in terms of an interaction of the primary meson with the nucleus of an atom in the emulsion leading to the production of an energetic meson of the same mass as the first. It was therefore suggested that the observations indicate the existence of mesons of different mass. Since the argument in support of this view relied entirely on the principle of the conservation of energy, a search was made for processes which were capable of yielding the necessary release of energy, irrespective of their plausibility on other grounds. Dr. F. C. Frank has re-examined such possibilities in much more detail, and his conclusions are given in an article to follow. His analysis shows that it is very difficult to account for our observations, either in terms of a nuclear disintegration, or of a 'building-up' process in which, through an assumed combination of a negative meson with a hydrogen nucleus, protons are enabled to enter stable nuclei of the light elements with the release of binding energy. We have now found it possible to reinforce this general argument for the existence of mesons of different mass with evidence based on grain-counts.

We have emphasized repeatedly[1] that it is necessary to observe great caution in drawing conclusions about the mass of particles from grain-counts. The main source of error in such determinations arises from the fugitive nature of the latent image produced in the silver halide granules by the passage of fast particles. In the case of the μ-decay process, however, an important simplification occurs. It is reasonable to assume that the two meson tracks are formed in quick succession, and are subject to the same degree of fading. Secondly, the complete double track in such an event is contained in a very small volume of the emulsion, and the processing conditions are therefore identical for both tracks, apart from the variation of the degree of development with depth. These features ensure that we are provided with very favourable conditions in which to determine the ratio of the masses of the π- and μ-mesons, in some of these events.

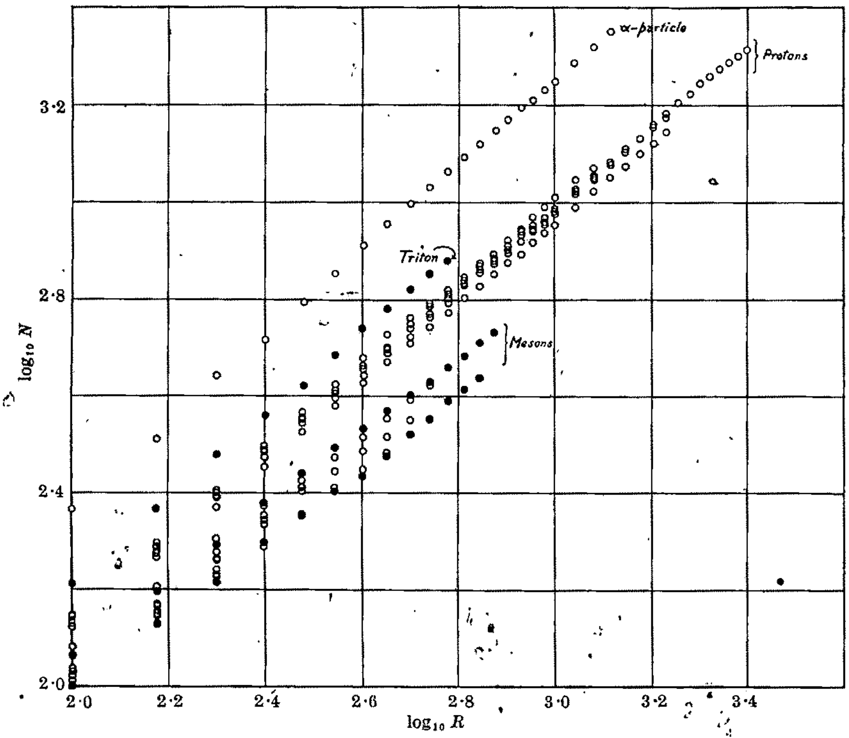

Fig. 4. N IS TOTAL NUMBER OF GRAINS IN TRACK OF RESIDUAL RANGE R (SCALE-DIVISIONS). 1 SCALE-DIVISION = 0·85 MICRONS

In determining the grain density in a track, we count the number of individual grains in successive intervals of length 50 μ along the trajectory, the observation being made with optical equipment giving large magnification (× 2,000), and the highest available resolving power. Typical results for protons and mesons are shown in Fig. 4. These results were obtained from observations on the tracks in a single plate, and it will be seen that there is satisfactory resolution between the curves for particles of different types. The 'spread' in the results for different particles of the same type can be attributed to the different degrees of fading associated with the different times of passage of the particles through the emulsion during an exposure of six weeks.

Applying these methods to the examples of the μ-decay process, in which the secondary mesons come to the end of their range in the emulsion, it is found that in every case the line representing the observations on the primary meson lies above that for the secondary particle. We can therefore conclude that there is a significant difference in the grain-density in the tracks of the primary and secondary mesons, and therefore a difference in the mass of the particles. This conclusion depends, of course, on the assumption that the π- and μ-particles carry equal charges. The grain-density at the ends of the tracks, of particles of both types, are consistent with the view that the charges are of magnitude | e |.

A more precise comparison of the masses of the π- and μ-mesons can only be made in those cases in which the length of the track of the primary meson in the emulsion is of the order of 600 μ. The probability of such a favourable event is rather small, and the only examples we have hitherto observed are those listed as Nos. III and VIII in Table 1. A mosaic of micrographs of a part only of the first of these events is reproduced in Fig. 1, for the length of the track of the μ-meson in the emulsion exceeds 1,000 μ. The logarithms of the numbers of grains in the tracks of the primary and secondary mesons in this event are plotted against the logarithm of the residual range in Fig. 5. By comparing the residual ranges at which the grain-densities in the two tracks have the same value, we can deduce the ratio of the masses. We thus obtain the result $m_\pi/m_\mu = 2\cdot0$. Similar measurements on event No. VIII give the value 1·8. In considering the significance which can be attached to this result, it must be noticed that in addition to the standard deviations in the number of grains counted, there are other possible sources of error. Difficulties arise, for example, from the fact that the emulsions do not consist of a completely uniform distribution of silver halide grains. 'Islands' exist, in which the concentration of grains is significantly higher, or significantly lower, than the average values, the variations being much greater than those associated with random fluctuations. The measurements on the other examples of μ-decay are much less reliable on account of the restricted range of the π-mesons in the emulsion; but they give results lower than the above values. We think it unlikely, however, that the true ratio is as low as 1·5.

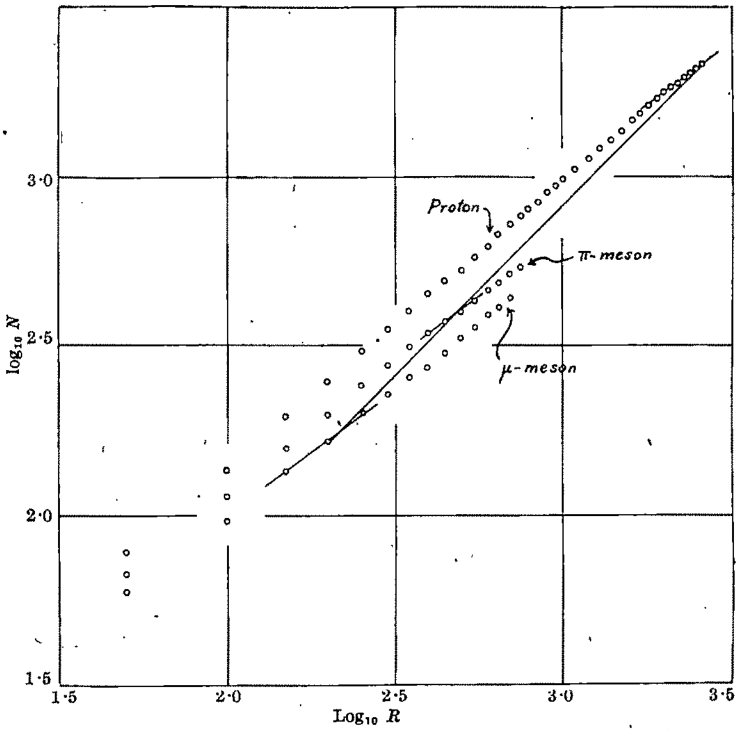

Fig. 5. N IS TOTAL NUMBER OF GRAINS IN TRACK OF RESIDUAL RANGE R (SCALE-DIVISIONS). 1 SCALE-DIVISION = 0·85 MICRONS
THE 45°-LINE CUTS THE CURVES OF THE MESONS AND PROTON IN THE REGION OF THE SAME GRAIN DENSITY

The above result has an important bearing on the interpretation of the μ-decay process. Let us assume that it corresponds to the spontaneous decay of the heavier π-meson, in which the momentum of the μ-meson is equal and opposite to that of an emitted photon. For any assumed value of the mass of the μ-meson, we can calculate the energy of ejection of the particle from its observed range, and thus determine its momentum. The momentum, and hence the energy of the emitted photon, is thus defined; the mass of the π-meson follows from the relation

$$c^2m_\pi = c^2m_\mu + E_\mu + h\nu.$$

It can thus be shown that the ratio m_π/m_μ is less than 1·45 for any assumed value of m_μ in the range from 100 to 300 m_e, m_e being the mass of the electron (see Table 3). A similar result is obtained if it is assumed that a particle of low mass, such as an electron or a neutrino, is ejected in the opposite direction to the μ-meson.

TABLE 3

Assumed mass m_μ	E (MeV.)	$h\nu$ (MeV.)	m_π	m_π/m_μ ± 3 per cent
100 m	3·0	17	140 m_e	1·40
150	3·6	23	203	1·35
200	4·1	29	264	1·32
250	4·5	34	325	1·30
300	4·85	39	387	1·29

On the other hand, if it is assumed that the momentum balance in the μ-decay is obtained by the emission of a neutral particle of mass equal to the μ-meson mass, the calculated ratio is about 2·1 : 1.

Our preliminary measurements appear to indicate, therefore, that the emission of the secondary meson cannot be regarded as due to a spontaneous decay of the primary particle, in which the momentum balance is provided by a photon, or by a particle of small rest-mass. On the other hand, the results are consistent with the view that a neutral particle of approximately the same rest-mass as the μ-meson is emitted. A final conclusion may become possible when further examples of the μ-decay, giving favourable conditions for grain-counts, have been discovered.

NATURE PROTECTION IN GREAT BRITAIN

THE concept that Nature cannot look after itself and needs protection from the ravages of man in the interests of man is comparatively modern. The problem arose only when the increasing use of coal, the invention of steam power, and the consequent entry into the industrial age led to a large expansion of the population and its concentration into particular areas, as happened in Great Britain. The reservation of small tracts to prevent the extermination of rare plants is no novelty; in Switzerland certain plants, one being the edelweiss, have been protected in this way for a long time. The idea, however, that a whole region should be kept inviolate for all time from exploitation and development, for the benefit of the people, is comparatively recent.

The creation of what are called 'national parks' first happened in the United States of America. Some three-quarters of a century ago, a party of white explorers penetrating into what is now the Yellowstone National Park were so impressed with the stupendous grandeur of the scene that spontaneously and unanimously they decided that it ought to become the property of the nation. This expression of opinion was accepted by the Government, and by the Yellowstone Park Act of Congress of 1872 the first national park was established "as a pleasuring ground for the benefit and enjoyment of the people", to quote the Act. Thus was set in motion a movement which spread over not only the United States but also much of the civilized world. The largest of the national parks is the Kruger National Park in South Africa, and a notable one is the Albert National Park in the Belgian Congo.

The term used for these wild spaces has been criticized, because the work 'park' connotes an artificially laid out and maintained piece of land or a site for assembling vehicles, for example, artillery or automobiles. It is, however, useless at this late date to think of changing it, especially as an alternative, short of coining a new word, would be difficult, if not impossible, to suggest. There are two distinct and mutually incompatible concepts of the purpose of a national park. The first is the conservation of the scene and the wild life contained in it, which necessarily entails the restriction of human access. Obviously, vegetation cannot remain unimpaired if humanity in its thousands is allowed to roam over it, and to pluck flowers and uproot plants at will. In the Swiss National Park no one is allowed to stray from the high road except by permission or under guidance, and no interference with natural processes is tolerated; even fallen trees are allowed to decay in peace. The second concept is the use of the area as a public pleasure ground. In the enormous stretches of national parks in the United States and elsewhere the two concepts may easily be harmonized, for there is ample space for the accommodation and amusement of tourists without sensible encroachment upon the natural scene. Even so, warding is necessary, in order to ensure that tourists obey regulations and do no harm, especially by starting fires which may do extensive damage. The importance of a biological service to take advantage of the national park as a great natural laboratory for the study of plant and animal associations and of the relation to the character of the soil needs no stressing.

The creation of national parks in a small and densely populated country like Great Britain, and particularly England and Wales, is a very different problem. Here are no large virgin regions which may be declared public property without disturbance of private ownership or local administration, and national parks, from which the public would be largely excluded in the interest of the wild life there, are not feasible. On the other hand, Great Britain, though so small in extent, is favoured with beautiful landscape of a remarkably varied character, ranging from the grandeur of the Scottish Highlands and the Welsh mountains, the open expanse of the Yorkshire moors, and the contrasting combination of fell and water in the Lake District, to the rolling downs and smiling fields of the south. Such landscape is a great national asset and should be treated as such, and the establishment of national parks in this sense is highly desirable. The initiation of the movement to this end is due to the Council for the Preservation of Rural England, which in 1929 submitted a memorandum on the subject to the then Prime Minister. In consequence a Government committee under the chairmanship of Dr. Christopher (now Viscount) Addison was appointed to consider the desirability and feasibility of establishing national parks in Great Britain. The report[1], which favoured such establishment, appeared two years later; but unhappily the economic crisis supervened and nothing was done to implement its recommendations. The matter might, indeed, have passed into oblivion but for the action of the Council, which, in conjunction with the similar body for Wales, set up in 1935 the Standing Committee on National Parks, composed of representatives of the organisations that presented evidence to the Addison Committee. By means of questions in Parliament and in other ways the subject was kept alive. A debate was being planned in the House of Lords in the summer of 1939, when the imminence of war brought progress to a standstill.

The setback proved to be only temporary; planning was in the air, and the possible provision of national parks and Nature reserves could not be ignored in schemes for the use of the land. In the report[2] of the committee under the chairmanship of Lord Justice Scott the establishment of national parks and Nature reserves was recommended and, for the first time in an official document, the preservation of geological monuments was advocated. Under the auspices of the Society for the Promotion of Nature Reserves, a Conference on Nature Preservation in Post-War Reconstruction, composed of delegates representing national societies interested in the subject and organisations of local authorities, was convened in 1941, and reported[3] that, as regards national parks: (*a*) steps should be taken to implement generally the recommendations of the National Park Committee made in its report, and in particular to set up national park authorities, which would be responsible for matters of general policy, one for England and Wales and one for Scotland, with a joint committee to co-ordinate the working of the two; (*b*) the management and administration of areas comprised in national parks and Nature reserves should, so far as desirable, be undertaken locally, in which matter local authorities should play the leading part with the help of persons with special knowledge or interest; and (*c*) the facilities given to the public and students on Government properties should be considered and made part of a unified policy for the needs here discussed. As regards

Nature reserves, (*a*) the principle of establishing Nature reserves and sanctuaries should be accepted as part of the general national planning schemes; (*b*) an official body, representative of the scientific interests concerned, should be appointed to draw up detailed proposals; and (*c*) the management of reserves and sanctuaries should be placed only in the hands of persons fully conversant with the highly technical problems included in the maintenance of the balance of life, and the general control should be vested in a central authority, representative of the different interests concerned. At the same time, the Conference recommended the official recognition of what were afterwards known as conservation areas, which should be preserved in their present, unspoilt state. The Conference's short but valuable document has scarcely received the attention its importance deserves.

But the Conference did not stop there, and in 1942, in response to official request, appointed the Nature Reserves Investigation Committee. Without assistance from public funds and with the aid of only a small grant from the Pilgrim Trust, this Committee, despite the perils of those tragic years, carried out a comprehensive natural history survey of England and Wales. Though taken for granted at home, this work at such a time aroused wondering amazement abroad. It first issued a memorandum[4] on general principles, and then created an elaborate machine made up of twenty-four regional committees and a geological sub-committee. As the result of their investigations two memoranda were published: the first[5] on geological features and the second on wild life[6]. The separate regional reports were not published, but they were duplicated and thus made available to planning authorities and officers. Almost simultaneously a Committee of the British Ecological Society produced two reports[7].

A further stage was reached when Mr. John Dower, formerly drafting secretary of the Standing Committee on National Parks, was enlisted by the newly formed Ministry of Town and Country Planning to study the problem of national parks so far as it affected England and Wales. He submitted an elaborate and detailed report[8]. Its public welcome impelled the Ministry to delve still deeper into the complex questions involved, and to appoint a committee under the chairmanship of Sir Arthur Hobhouse for the purpose of considering the Dower Report, and making recommendations for the selection, delimitation, and administration of national parks, and for ancillary matters, including the conservation of wild life and the provision of footpaths and access to the countryside. The conservation of wild life was referred to a special committee, of which Dr. Julian Huxley was chairman and Prof. A. G. Tansley vice-chairman, and the other matter to another special committee under the chairmanship of Sir Arthur himself.

In the principal report[9] the desirability of national parks is accepted; but it is realized that their function will be more the spiritual and bodily refreshment of the people, especially the inhabitants of cities and towns, than the protection of wild life. The Committee recommends that their control should be entrusted to a National Park Commission, which would be responsible to the Minister of Town and Country Planning. Twelve areas are selected as national parks, to be created in three annual instalments. Of these, nine are in category *A* of the Dower Report, two are in category *B* and one is in category *C*; the last, the South Downs, is raised in status because of its proximity to London. Their management is to be handed to park committees, of which the chairman and one half of the other members would be appointed by the Commission and the other half by the local authorities concerned, an arrangement that may be expected to prove satisfactory provided that the two halves work in harmony and not in opposition. The main function of the Commission would be to control the development and use of the land of the national parks; conflict with Government departments is to be resolved by a permanent committee of the Cabinet created for the purpose. The setting up of a Coastal Planning Advisory Committee is recommended, and the need for national planning to resist coastal erosion is realized. The total capital cost is estimated to be £9,250,000, some of which, at least, would be suitable for grants from the Land Fund. In addition to the main areas the Minister is recommended to declare other similar, but smaller, tracts 'conservation areas', a term introduced by the Nature Reserves Investigation Committee, to be controlled by advisory committees. The total annual cost of all areas in Britain is estimated to be £170,000, rising eventually to £750,000.

The scope of the second report[10] covers more than the areas selected as national parks, since tracts of scientific interest whether for their wild life or for their geological features are not necessarily restricted to them. Frank and full acknowledgment is made of the value of the work of the Nature Reserves Investigation Committee, and the recommendations of the latter body for national Nature reserves and conservation areas and for geological features are adopted with but slight modifications. Reference is made also to the reports of the British Ecological Society mentioned above. Stress is laid upon the necessity for the proper maintenance of these natural features and the investigation of their scientific characters, and the establishment of a biological service for the purpose under the control, initially at least, of the Lord President of the Council, is recommended; specialists when needed would be seconded from the Geological Survey or the British Museum (Natural History). From the reference to the Society for the Promotion of Nature Reserves, it might be supposed that it depended for its income mainly on the endowment by the Hon. Charles Rothschild. Unhappily, at the present time that part of its income barely suffices to meet half the cost of maintaining the Nature reserve given by him and added to by his wife. The Society defrays its other activities almost entirely from the income from the far larger bequest made by Dr. G. Claridge Druce.

During recent years, distinct but complementary work has been carried on in Scotland. At the instance of the Association for the Preservation of Rural Scotland, the Scottish Council for National Parks was set up in 1943. The Scottish National Parks Survey Committee, with Sir J. Douglas Ramsay as chairman, was appointed in 1944, and in its report[11], which was issued soon after the Dower Report, various areas are recommended as national parks and various tracts as Nature reserves. The Scottish National Parks Committee under the same chairmanship was formed early in 1946 to study the detailed arrangements entailed by the previous proposals, and the Scottish Wild Life Conservation Committee, with Prof. James Ritchie as chairman, was appointed to advise it on the natural history aspect.

It is not unduly rash to say that a long way has been traversed towards the realization of the vision that inspired a few enlightened men and women eighteen years ago. Then it faded and all but vanished under the chill blast of the economic blizzard. Now that the vision once more seems on the point of taking shape, it has to face yet another such crisis. If a similar fate is not to befall it, the Government must be urged to appoint forthwith the National Parks Commission and at least the nucleus of the biological service. G. F. HERBERT SMITH

OBITUARIES

Prof. E. Laqueur

THE death of Prof. Ernst Laqueur at the age of sixty-eight occurred on August 19, while he was on holiday in Switzerland.

Laqueur's death removes from the field one of the pioneers of modern endocrinology, and particularly that branch of it dealing with the sex hormones. Laqueur had had a very sound training in both chemistry and biological methods, and was himself also a qualified physician. This latter training gave him that great interest in the practical application of scientific work which undoubtedly acted as a stimulus for his investigations into the internal secretions.

His first major contribution to the subject of endocrinology occurred in the very early days of insulin. In the close of the year 1922, Banting and Best had published their classical paper demonstrating the presence of a stable anti-diabetic substance in the pancreas. From that moment biochemists all over the world concentrated on attempts to make possible the production, on an economic basis, of this new substance, insulin. Well in the forefront of this investigation was Prof. Laqueur with his team at Amsterdam. They made a large number of very important communications on both the preparation and the properties of insulin.

It was, however, mainly on the question of the sex hormones that Prof. Laqueur's reputation rests. It will be remembered that in 1924 Allen and Doisy started an entirely new epoch in research on the female sex hormone by applying the vaginal smear method of Stockard and Papanicolaou to the standardization of the ovarian hormone, as it was then called. Prof. Laqueur immediately started work on similar lines and was certainly in possession of one of the purest specimens of the hormone up to the time of the announcement by Aschheim and Zondek of the presence of the hormone in the urine of pregnancy. Again, this discovery completely changed the whole outlook on the biochemical research into the nature of the hormone; but again Prof. Laqueur was well in the forefront in the crystallization of the hormone from the new source.

In the early 1930's, Butenandt had succeeded in isolating a steroid substance from male urine. This substance, androsterone, proved to have the properties of the male sex hormone in that it was capable of causing growth of the capon's comb. Laqueur was the first to point out that an extract of the testis could be obtained which was more powerful, weight for weight, than the actual crystalline androsterone. At first Laqueur inclined to the view that there was some activator present in the testes and suggested the name of the '*X* substance'. Later, however, he characterized the actual hormone and named it 'testosterone'. This research was brought into line with the brilliant discoveries being made at Zurich in the laboratories of Prof. Ruzicka. He had shown that by oxidizing away the side-chain of sterols such as cholesterol, it was possible to obtain the cyclopenteno-phenanthrene nucleus with the right stereochemical configuration, and that this could be used as a basis for the partial synthesis of sex hormones. Testosterone is produced by this method. We have, therefore, in this brilliant research of Prof. Laqueur an excellent example in which skilful and penetrating biological observational work can be combined with organic chemistry, leading to the isolation, characterization and large-scale production of new compounds.

Prof. Laqueur was a frequent visitor to Britain and was well known to all those who worked in this field through his assistance at the various international congresses before the War. With the invasion of Holland by the Germans he was removed from his post, and both he and his family were subjected to the cruellest of treatment. He emerged from the War with severely impaired health, but those who saw him after his ordeal commented on his completely unbroken spirit.

Holland and the science of endocrinology have lost a great pioneer. E. C. DODDS

Prof. Ll. Rodwell Jones

BY the death on August 15 of Ll. Rodwell Jones, shortly before his sixty-sixth birthday, British geography has lost one of its rapidly dwindling group of 'elder statesmen'.

Rodwell Jones was born on August 28, 1881. In due course he proceeded from Kingswood School, Bath, to the University of London, where he took a science degree, and then commenced school-teaching. It was while so engaged that he came under the stimulating influence of Mackinder, then at the London School of Economics, and found his vocation in geography. An appointment as lecturer in geography in the University of Leeds in 1913 was all too soon interrupted by the First World War, in which he served in the West Yorkshire Regiment, reached the rank of major and was decorated with the Military Cross. Shortly after his release from the army he returned to London to join Mackinder's staff at the London School of Economics, and in 1925 succeeded him as professor of geography and co-head of the King's College, London School of Economics Joint School of Geography. He had planned to retire on reaching the age of sixty, but the Second World War necessitated an unwelcome postponement, and it was not until 1945 that he felt justified in vacating his post.

It is difficult to assess with any confidence the relative value of Rodwell Jones's contributions to his subject. His output of published work was limited both by his devotion to the needs and interests of his very large department and by his extremely exacting standards of scholarship. He committed nothing to print until he had tested and re-tested materials and methods, and satisfied himself of the soundness of his conclusions. His major works, "Northern England", "North America" (in collaboration with Dr. P. W. Bryan), and "The Geography of London River" are, in consequence, not merely interpretations of first-class importance, but models of method as well. Yet it is as class teacher and research adviser that he will probably be most vividly and gratefully remembered by his students. Shy in nature, and lacking the platform brilliance of a Mackinder or a Lyde, he gained the respect, admiration and enduring affection of successive generations of students, who experienced at close range the humour and the kindliness behind his shyness, and were helped to acquire permanent habits of critical and constructive thinking in their subject.

NEWS and VIEWS

International Control of Atomic Energy

SIR CHARLES DARWIN opened a discussion on "Atomic Energy and the Veto" which formed part of the programme of a meeting of the Atomic Scientists' Association held at Oxford on September 20. He said he wanted to examine carefully the grounds on which a case might be built for treating atomic energy in a different way from other armaments, in the setting up of the proposed Atomic Development Administration and in its freedom from the veto. This he analysed coldly under seven headings: (1) pure military, (2) novelty, (3) mass destruction, (4) start of war, (5) treachery, (6) scale effect and (7) feasibility. Under the first three headings he found no reason for special treatment; but under the last three he found there is a definite case. The strongest argument is the unanimous report of the Atomic Energy Technical Committee of the United Nations Organisation that international control is, in fact, a workable proposition from a technical point of view. Sir Charles discussed the seven headings in some detail. In relation to (1), he said he thought that the atomic bomb is not a 'good weapon'. Although it would certainly be effective for use on naval bases, he did not believe it would be used for land warfare. In relation to (4), he said that although the bomb could deliver a tremendous blow, it could not prevent retaliation in kind, which he thought might act as a severe deterrent to its use. With regard to (5), he stressed the possible use of the bomb as a secret weapon of treachery by an unidentifiable third party in a dispute.

Prof. N. F. Mott, in thanking Sir Charles Darwin, said he thought there might be a case for 'de-bunking' the atomic bomb, but wondered whether Sir Charles had not 'de-bunked' it too much. Dr. W. J. Arrol stressed the importance from a purely military point of view of attacks on ports and convoys. The extreme danger of its use for attack on industry and for mass-destruction was implicit in the remarks of most of the speakers. Captain Blackburn, M.P., for example, said that the scientific men had done their job in showing that atomic control is technically feasible, and that the problem is now a political one. Control is being frustrated, he said, by the U.S.S.R., and he advocated an urgent meeting of Mr. Attlee and Mr. Truman with Mr. Stalin to put the danger to the latter in the plainest terms. Failing agreement, peace-loving nations must develop predominance in atomic and other power. Mr. Conybeare did not agree that the U.S.S.R. is frustrating control, and Dr. H. W. B. Skinner said that, while agreeing with most of Captain Blackburn's remarks, he deprecated the atmosphere of crisis. Dr. A. T. Waterman, a guest from the United States, stressed the value of international co-operation in science. Dr. K. Lonsdale asked whether there would be any purpose in the Association of Atomic Scientists calling on scientific workers not to take part in the manufacture of atomic weapons; but Prof. Mott thought that it would not be possible to secure a majority opinion on this suggestion. Another speaker complained of the placidity of the discussion of a situation in which we were running into another war, and there was some argument as to the future aim of the Association, Mr. Freedman, in particular, feeling a lack of guidance in the present dangerous situation. But Prof. R. E. Peierls said that, though scientific men should not be afraid of politics, policy must be clear-cut and united. Urgency does not replace judgment, and he felt that, at present, no straightforward lead could be given. The functions of the Association must therefore remain for the moment mainly educational.

Electron Jubilee Exhibition

To mark the fiftieth anniversary of the discovery of the electron, an exhibition, illustrating the scientific and industrial developments and the numerous electronic devices resulting from that discovery, is being held at the Science Museum, London. The exhibition is arranged around one gallery of the Museum, and is divided into eight sections, each of which is devoted to one particular aspect of the subject. By photographs, diagrams (some of which are animated), working exhibits, and the display of historical and modern apparatus, the visitor is shown how the wave-like and particle-like properties of the electron were discovered, and is given an appreciation of the way in which these discoveries have opened up a new era, both in science and industry.

An attractive handbook to the Exhibition, with an intriguing cover and a photograph of Sir J. J. Thomson, the discoverer of the electron, as frontispiece, has been prepared by Mr. D. H. Follett (Institute of Physics, London. 1*s.* 2*d.* post paid). It is in two parts. The first is a guide to the exhibition and lists the exhibits in the eight sections in the order in which they are displayed. The second is a descriptive account of the background to the several exhibits. It is well written, and the reader with some knowledge of physics will find that it gives an accurate summary of the history of the electron during the past fifty years. The subjects dealt with include: the discovery of the electron and the measurement of its charge; the thermionic valve and the cathode ray tube; the photo-electric effect and devices; atomic structure; electron diffraction; X-rays; and the conduction of electrons in gases and solids. It is a pity that no illustrations of the actual exhibits are given. Doubtless a third part to the handbook, similar to that produced for the 'low-temperature' exhibition several years ago, with photographs of the exhibits and exhibition, would receive a welcome. The exhibition will remain open to the public for three months.

Automatic Control on Atlantic Flight

A U.S. Air Force "Skymaster" transport aircraft flew from Stephenville, Newfoundland, to Brize Norton R.A.F. Station in Oxfordshire, on September 22, a distance of 2,400 miles across the Atlantic, including taking off and landing, without being controlled in any way by the crew on board. The machine was commanded by Colonel J. N. Gillespie of the U.S. Air Force, and carried a number of scientific observers as well as the normal crew. The apparatus automatically controls the take-off and climb to an arranged height. It then homes on a beam sent out by a radio beacon. In this case these came from two successive ships on the way across, and then from Brize Norton. Finally, it sets the machine into the required glide, lands and brakes. In the United States the system is understandably described as 'push button flying'.

The real significance of this system lies in the ability to make landings at the end of the flight. Automatic control of direction during a flight has been in use successfully for some time. A flight can now be commenced without fear as to what the weather conditions will be at the end of it. The radio control is independent of the weather and can land a machine under conditions in which human control would be impossible; in bad visibility, for example. The apparatus is such that it can be fitted to any aircraft of sufficient capacity; in fact, the machine which has just crossed the Atlantic was a standard Skymaster of the U.S. Air Force. The system would not be applicable to bombing raids, as it depends upon radio co-operation from the terminal point, which would not be available from the enemy territory.

Correspondence of Isaac Newton

ALTHOUGH Isaac Newton is acclaimed as the greatest leader of scientific thought that the world has known, there exists no satisfactory collected edition of his works. The Council of the Royal Society has decided to make a first step in the arduous undertaking of preparing such an edition by producing in a worthy form the collected correspondence of Newton, which will comprise letters written by him and the replies to them. Prof. H. W. Turnbull has undertaken the editorship of this work. The Council of the Royal Society has entrusted the immediate organisation of the publication of the Newton correspondence to a sub-committee of the Society, under the chairmanship of Prof. E. N. da C. Andrade. It is hoped that learned institutions, museums, libraries and collections will collaborate in the work, by notifying the assistant secretary of the Royal Society of any letters of Newtonian interest that they may possess, and by lending the letters to the Society for a brief period or by arranging with the Society for photographic copies to be made.

Overseas Broadcast of the British Association Meeting

A SERIOUS attempt was made by the B.B.C. to give listeners an account of the recent meeting of the British Association in Dundee, by bringing representative speakers to the microphone every day. A descriptive broadcast on Dundee and St. Andrews was also given in the B.B.C. overseas service to Germany on September 19, and repeated on September 23. The broadcast, recorded in German, included an account of the Dundee shipyards and of visits to marmalade and jute factories. There were also interviews at Dundee with Prof. J. D. Cockcroft on atomic energy, Sir Robert Watson-Watt on radar and Dr. E. B. Chain on penicillin. The account of the University of St. Andrews and of the ancient buildings of the city included interviews with Dr. C. T. Carr, lecturer in German, and Dr. John Read, professor of chemistry, whose reference to alchemical music was illustrated by a gramophone reproduction of one of Count Michael Maier's canons from "Atalanta Fugiens" (1618).

Heredity

RECENTLY there has appeared the first number of the new journal, *Heredity*, devoted, as its name indicates, to genetics (*Nature*, **159**, 599; 1947). In the past fifty years, this science has seen an expanding flow of publications—a flow which the War did little to check. Before 1939 this increase was matched by the increasing number of journals which offered facilities for the publication of findings in genetics; but far from the increase in means of publication continuing, the War has led to a reduction in the number of genetics journals in Europe. The appearance of a new one is therefore particularly welcome at the present time. *Heredity* is jointly edited by Dr. C. D. Darlington and Prof. R. A. Fisher, and it is published by Messrs. Oliver and Boyd of London and Edinburgh. Its international nature is emphasized by the board of five collaborating editors, of whom three are from Europe and two from the United States. The editorial policy is a liberal one both in the types of articles which will be accepted and in the fields from which they will be drawn. Historical, review and critical contributions will find their places beside the records of new research; and cytology, statistics, biochemistry, evolutionary theory and breeding work will all be accepted in so far as they are related to genetics. The new journal is to appear three times a year.

The first number of *Heredity* well illustrates how this editorial policy is put into practice. It contains ten articles, covering a wide field in their nature, in their subject-matter and in the countries from which they originate. The first two form a novel departure and one which should do much towards overcoming the consequences of difficulty in communication during the war years. These are, respectively, a summary of genetical research in Great Britain during 1939–45, and a bibliography of German and Italian research during the same period. Though running to some six hundred titles, this list is not complete in its German section, and a supplementary bibliography is promised. Two short papers describe a new gene and a new linkage in the mouse, and a third is devoted to the colour inheritance and sex-determination in the fish, *Lebistes*. From the plant side come two papers: one on the interaction of self-incompatibility genes when, contrary to their usual situation, two are present in the same pollen grain; and one on the theory of breeding plants for increased yield. Two further papers consider the effects of natural selection, in one as exemplified by change with time in frequency of certain chromosome types in *Drosophila*, and in the other by the change with climate in frequency of a gene causing a waxy bloom in *Ricinus*. Finally, there is a statistical discussion of the measurement and analysis of virulence in bacteria and viruses, as it might be applied to genetical work.

International Union of Biological Sciences

This Union held its first post-war meeting at Copenhagen at the end of July. It was attended by delegates from the various sections and from seventeen countries. Dr. Joseph Needham attended the meeting on behalf of the United Nations Educational, Scientific and Cultural Organisation, and Prof. Borel and M. Establier on behalf of the International Council of Scientific Unions. It was agreed to form new sections of experimental cytology, embryology, genetics, microbiology and zoology. In addition to the Joint Commission on Oceanography on which the Union is represented, it was agreed to form certain new committees on border-line subjects and to invite other unions to nominate members: the subjects agreed upon were radiobiology and natural calamities. A long list of congresses and symposia were notified for the year 1948. Proposals were discussed for the publication of a catalogue of type-specimens of animal species and of historic collections, for the distribution of artificial radioactive isotopes for biological experiments and for the creation of a centre for marine biology in the Malay Archipelago. A resolution was adopted urging that all possible means be taken to prevent biological warfare. It was agreed to hold the next meeting in 1950, probably in Stockholm. The following officers were elected: *President*, Dr. M. J. Sirks (Netherlands); *Vice-President*, Prof. H. Munro Fox (Great Britain); *General Secretary*, Prof. P. Vayssière (France); *Secretary*, Prof. Stuart Mudd (United States); and *Treasurer*, Prof. Chodat (Switzerland).

Chemistry and Uses of Fluorine

A whole number of *Industrial and Engineering Chemistry* (39, 236–435; March 1947) is devoted to the chemistry of fluorine and its compounds. The production of fluorine on the industrial scale and its storage and utilization are fully described. The common electrolytes are fused acid potassium fluorides with carbon anodes, and up to 2,000 amperes were used in the electrolysing currents. An anode current efficiency of about 95 per cent was attained. Small laboratory units are also dealt with. The gas can be piped in steel or copper, and compressed up to 400 lb./in.^{2} in nickel and steel cylinders. Purification reached 98 per cent minimum. Fluorination of hydrocarbons formed numerous products up to $C_{18}F_{30}$, and in this work much use was made of cobalt trifluoride, CoF_3, and silver difluoride, AgF_2, and reactions in liquid hydrogen fluoride. A novelty is the fluorine-hydrogen blowpipe, used for welding metals. The papers represent a notable advance in fluorine chemistry.

Archæological Work in China

Occasional Papers (vol. 1, No. 1) of the Freer Gallery of Art (Smithsonian Institution) is devoted to a description of the tomb of the Grand Empress Dowager Wên Ming and the Northern Wei necropolis at Fang Shan. The author (A. G. Wenley) has produced an interesting little work of some 28 pages with six full-page photographs of the site. It starts with a short account of the Empress Dowager herself, followed by a description of the necropolis and tomb where she is buried. The work itself is dedicated to the late Carl Whiting Bishop, who was associated with the Freer Gallery for twenty years and who was much interested in certain Northern Wei dynasty imperial mausolea.

German Food Industry in War-time

An exhibition of photographs, drawings and specimens obtained in Germany by British Intelligence Objectives Sub-Committee investigating teams sponsored by the Ministry of Food will be on view in the Conference Hall, Portman Court, Portman Square, W.1, during October 15–29 each day from 10 a.m. to 4 p.m. Informal talks will be given in the exhibition at 3 p.m. on German soapless detergents (Mr. G. R. Perdue, British Launderers' Research Association); developments in the German dairying industry (Mr. F. C. White, Ministry of Food); war-time production of food yeast in Germany (Mr. H. J. Bunker, Barclay Perkins and Co., Ltd.); food preservation and refrigeration in Germany (Dr. E. C. Bate-Smith, Department of Scientific and Industrial Research).

University of London: Appointments

The following appointments in the University of London have been announced: Mr. M. McGregor Cooper, senior lecturer in dairy husbandry at Massey Agricultural College, New Zealand, to the University chair of agriculture tenable at Wye College; Prof. W. J. Hamilton, since 1945 regius professor of anatomy in the University of Glasgow, to the University chair of anatomy tenable at Charing Cross Hospital Medical School; Prof. W. G. Holford, since 1931 Lever professor of civic design in the University of Liverpool, to the University chair of town planning tenable at University College; Dr. W. A. Lewis, lecturer in commerce at the London School of Economics and also principal in the Board of Trade and in the Colonial Office, to the University readership in Colonial economics tenable at the School.

The title of reader in mining geology in the University has been conferred on Dr. David Williams, in respect of the post held by him at the Imperial College of Science and Technology.

Announcements

The sixth Hinchley Memorial Lecture of the Institution of Chemical Engineers will be delivered by Dr. R. V. Southwell, rector of the Imperial College of Science and Technology, on October 14 at 5.30 p.m. at the Institution of Mechanical Engineers, Storey's Gate, London, S.W.1. Dr. Southwell will speak on "Relaxation Methods: a Method for the Engineer".

Dr. E. Ashworth Underwood, director of the Wellcome Historical Medical Museum and honorary lecturer in the University of London (University College), has been awarded the Cross of the Chevalier of the Legion of Honour.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications

Mode of Action of 'Paludrine'

INVESTIGATING the activity of 'Paludrine' against plasmodia in tissue culture, Tonkin[1] and Hawking[2] concluded that the drug was inactive *in vitro*, but was metabolized to an active form in the serum of the host. In view of these observations, it surprised us to find that 'Paludrine' inhibited the oxidation of glucose, pyruvate and lactate by washed chick red cells parasitized with *P. gallinaceum* more powerfully than did quinine (Table 1).

TABLE 1

Inhibitor	Conc.	% inhibition of oxygen uptake after 2 hours		
		Glucose	Pyruvate	Lactate
'Paludrine' HCl	1/300,000	4·6	Nil	Nil
	1/60,000	20·7	2·5	24·1
	1/6,000	84·5	84·0	89·4
Quinine HCl	1/60,000	10·4	5·6	5·5
	1/6,000	15·8	15·6	5·5

Determinations of glucose utilization and changes in phosphorylated intermediates in parasitized red cell incubates in the presence of 'Paludrine' and of iodoacetic acid showed that 'Paludrine' inhibition was essentially different from that of the iodoacetate (Table 2). While the latter inhibited both oxygen consumption and glycolysis, with accumulation of hexose phosphates, 'Paludrine' showed less than 50 per cent inhibition of glucose utilization, although oxygen consumption was inhibited to a greater extent. Similar observations on quinine indicated that it inhibited glycolysis rather more strongly than oxidations, probably by inhibiting the hexokinase reaction[3].

TABLE 2

	Inhibitor	Conc.	μ Mols used up (−) or formed (+) per hour per 100 μ mols glucose used by controls							
			Glucose	A.T.P.	Glucose-6-phos.	Fructose-6-phos.	Phospho-glyceric acid	Pyruvic acid	Lactic acid	Oxygen
Expt. 1	Control	—	−100	−141	−23·8		+91·3	+17·5	+625	−266
	'Paludrine' HCl	1/6,000	−69	−74	−31·3		+26·2	+13·8	+313	−31
	Iodoacetic acid	1/6,000	−11	−55	−7·4		+51·0	+2·9	+31	−58
Expt. 2	Control	—	−100	−66	−3·5	+0·7	−3·4	+3·0	−118	−71
	'Paludrine' HCl	1/3,000	−54	−26	−2·6	+1·0	+0·5	+4·3	−187	−5
	Iodoacetic acid	1/3,000	−13	−97	+8·9	+2·6	−3·1	+0·7	−414	−12

These observations suggest that 'Paludrine' exerts its anti-malarial action, at least partially, by inhibiting the oxidation processes in the parasites, but does not directly effect the anaerobic breakdown of glucose to lactic acid. However, higher concentrations of 'Paludrine' than those used by Tonkin and Hawking were necessary, particularly in the phosphorylation experiments, in order to produce measurable changes, and in the comparative experiments with quinine the greater inhibitory action of 'Paludrine' was more marked at high than at low concentration. It may be, therefore, that inhibition of oxidative processes does not play such an important part where 'therapeutic' concentrations of the drug are concerned.

β-Glucuronidase and Tissue Damage

AFTER repeated feeding of menthol to mice, Fishman[1] obtained results which on statistical examination showed an increase in β-glucuronidase in liver, spleen and kidney as compared with organs from untreated animals. Similar results were obtained in dogs fed with borneol. Since the compounds examined are known to be excreted as the glucuronides in certain species, Fishman considered β-glucuronidase to be responsible for glucuronide synthesis *in vivo*, and that he was measuring adaptation on the part of the enzyme in response to the presence of excess substrate. The work of other authors is not, however, compatible with the view that the function of β-glucuronidase in the body is other than hydrolytic[2,3,4].

Using biosynthetic phenol β-*d*-glucuronide[5] for the assay of glucuronidase[6], an attempt was made to confirm Fishman's findings with menthol. Twenty-four hours after intraperitoneal injection of *l*-menthol in vegetable oil into mice there was a marked rise in glucuronidase in liver, but not in kidney. It was difficult to decide whether the spleen enzyme was affected because of the great variation in normal values observed with this organ. Average normal values were the same in the case of each organ for mice of both sexes and drawn from three different colonies. The rise in liver glucuronidase was less marked after repeated feeding of menthol than after injection of much smaller doses.

It was observed that menthol caused gross damage to the liver, but not to the kidneys, and it was considered that this property, rather than the one of giving rise to a glucuronide, might explain the effect on liver glucuronidase. A variety of other substances, known to cause damage to the liver or kidneys, but with one exception unlikely to form glucuronides, were therefore examined for their effects on glucuronidase. Compounds which are relatively non-toxic, but which are known or considered to form glucuronides in the body, were also examined. The substances were injected subcutaneously or intraperitoneally in oil or aqueous solution into groups of 3–9 mice, and the animals were killed after 1–3 days. With several of the substances, the organs were examined histologically

Substance	Dose gm./kgm.	G.U.*/gm. moist tissue			Histological findings
		Spleen	Liver	Kidney	
Normal mice	—	580	280	378	—
Liver poisons					
l-Menthol	0·33	777	933	285	Moderate fatty degeneration and necrosis of liver, with evidence of repair, all most marked with carbon tetrachloride. Little deviation from normal in kidney and spleen.
l-Menthol β-*d*-glucuronide	2·3	995	1104	295	
Carbon tetrachloride	5·33	840	1138	139	
Chloroform	2·0	1079	939	194	Not done.
Kidney poison					
Mercuric nitrate	0·02 to 0·04	718	469	808	Kidney was profoundly damaged, with marked necrosis in the medullary region and hyaline casts. Liver and spleen showed little change from normal.
Liver and kidney poisons					
Yellow phosphorus	0·0075	506	91	338	Marked fatty degeneration of liver with no signs of repair. Small areas of necrosis in kidney, most marked in cortex. Spleen as normal.
Phenyl arsenoxide†	0·001 to 0·002	807	257	471	Extensive fatty changes in liver with severe necrosis and no evidence of repair. Kidney as with phosphorus, but changes more obvious. Spleen as normal.
'Non-toxic' compounds					
Sulphathiazole	43	561	460	368	Not done
Pregnanediol‡	0·33	1001	287	321	
Pregnanediol‡ β-*d*-glucuronide	0·80	627	241	264	

* One G.U. (glucuronidase unit) liberates 1 μgm. phenol from 0·015*M* phenol glucuronide at 38° and *p*H 5·2.
† This compound could conceivably give rise to a glucuronide.
‡ Injected as a suspension in oil.

by Mr. J. G. Campbell of the Royal (Dick) Veterinary College, Edinburgh. As shown by the averaged results in the table above, a significant rise in the β-glucuronidase level only occurred when an organ showed obvious, but not irreparable, damage.

Phenylarsenoxide had no effect on the glucuronidase level in liver or kidney, while phosphorus actually depressed it in the case of liver. Both substances, however, caused extensive damage. These results favour the view that a rise in glucuronidase is associated with tissue regeneration following moderate damage rather than with the damage itself. A series of experiments is in progress to settle this point. The effects observed with menthol glucuronide were presumably due to liberation of menthol by glucuronidase initially present in the body, and are difficult to reconcile with Fishman's views. The rise in liver glucuronidase caused by carbon tetrachloride may to some extent explain its enhancing action on the effect of œstrogens[7], since glucuronide formation plays some part in the metabolism of the latter compounds. It is interesting to note that both carbon tetrachloride[8] and chloroform[9] are known to produce hepatomata after repeated administration to mice. The possibility of menthol behaving similarly is under investigation. In a recent communication to *Science*, Fishman[10] gives figures showing that in some cases of human carcinoma the tumour contained much more glucuronidase than the corresponding normal tissue. He suggests that this may be due to excessive local accumulation of œstrogens. In view of the bearing of our results on this finding, it was considered that an interim account should be published without further delay.

The Sulphatase of Clarase

'CLARASE'*, an enzymatic preparation containing mainly amylase and in smaller amounts maltase, protease, peptidase, lipase and other enzymes, has now been shown to possess sulphatase activity. This sulphatase appears to be mainly phenolsulphatase. Other sulphatases (glucosulphatase[1], chondrosulphatase[2] and myrosisnase[3]) from various sources have been described by different authors.

Conditions for the activity of sulphatase of 'Clarase' were examined; the optimum *p*H was found to be about 6.

Of the buffers used the $M/7 \cdot 5$ phosphate was found to be most suitable. A slight inhibition was observed with acetate buffer and a very marked one with B.D.H. universal buffer.

The sulphatase of 'Clarase' hydrolyses the ethereal sulphates of horse urine, but not to such an extent as the takadiastase described by Noguchi[4]. Under comparable conditions only 24 per cent of the ethereal sulphates were hydrolysed as against 93 per cent reported by Noguchi. Contrary to the opinion of Noguchi, who ascribes the high percentage of hydrolysis to favourable conditions prevailing in horse urine, it was found that the sulphatase of 'Clarase' is actually inhibited by that medium, as is shown in the accompanying table:

INHIBITION OF SULPHATASE BY HORSE URINE

(Percentage hydrolyses of the ethereal sulphates of horse urine compared with those of potassium phenylsulphate in phosphate buffer; the concentrations of substrates expressed as SO_3 are equal.)

	Control		2% 'Clarase'		4% 'Clarase'	
Time (days)	Horse urine	Phosphate buffer	Horse urine	Phosphate buffer	Horse urine	Phosphate buffer
1	0·6	0·8	20·0	53·2	41·2	72·0
3	1·2	2·6	23·4	55·4	44·4	84·9
5	1·4	3·2	24·4	60·2	47·0	93·0

(The chief ethereal sulphates found in horse urine besides potassium phenylsulphate, namely, indican and potassium-tolylsulphate, were shown to be hydrolysed by the sulphatase of takadiastase to approximately the same extent[5,6].)

Human urine was also proved to exert an inhibitory effect on the sulphatase of 'Clarase', though to a lesser degree.

It is possible that urea is the substance partially responsible for the inhibition by both horse and human urine, as in pure buffer solution it inhibits the activity of sulphatase; the degree of inhibition is dependent on the concentration of urea.

* Produced by Takamine Laboratory, Inc., Clifton, N.J.

When potassium phenylsulphate, which was used as substrate in the above experiments, is replaced by potassium dimethyl-phenylsulphate, a reduction in the rate of hydrolysis is observed. Hence introduction of aliphatic radicals into the benzene ring of potassium phenylsulphate seems to hinder the activity of the enzyme. This effect is still more marked when carvacryl (2-methyl-5-isopropyl) sulphate is used as substrate.

A fuller account of these investigations will be published shortly.

Fructose and the Reducing Value of Insects' Blood

THE reducing value of the blood or hæmolymph of insects is a very variable quantity, depending both on species and on the stage of the life-history[1,2]. However, all observations agree that the true blood sugar accounts for only a fraction, usually considerably less than 30 per cent, of the total reducing value. On the grounds that this fraction is yeast fermentable, and that in a few cases a glucosazone has been obtained, this sugar has been considered as glucose[2-4].

The total reducing value of the hæmolymph of the 3rd instar larva of the fly *Gastrophilus intestinalis*, parasitic in the stomach of the horse, averages 356 mgm. per cent, calculated as glucose; of this value the high figure of some 200 mgm. per cent or 60 per cent is fermentable by yeast and constitutes the reducing blood sugar. Previous workers[5,6] have suggested that glucose is present in the hæmolymph; but in view of the following evidence, the whole of the fermentable sugar may be accounted for by the content of fructose.

The deproteinized hæmolymph gives a strongly positive resorcinol (Seliwanoff) reaction and the glucosazone was isolated. Following the advice of Dr. D. J. Bell[7], the β-diacetone fructose compound was crystallized from a pooled blood sample. The melting point (uncorrected) was 94·5° C., while the mixed melting point obtained with a sample prepared from pure fructose was 94·2° C. Employing the quantitative method of Roe[8], I have found the fructose content of the blood to vary from 184 to 294 mgm. per cent.

If a blood sample be allowed to stand, fructolysis occurs spontaneously. In a blood sample allowed to stand for two hours at 37° C. the fructose content decreased by 14 per cent, while the blood lactic acid increased by 48 per cent. The fructose is almost entirely in the free, that is, non-phosphorylated state.

Adapting the Roe method for a qualitative as well as a quantitative test, no appreciable amounts of fructose were found in the blood of the adult locust (*Schistocerca* sp.), the larva of the wax moth (*Galleria mellonella*), or in the late third instar larva or adult of the blow-fly (*Calliphora erythrocephala*). Values found for the two stages of the latter species were 14 mgm. per cent and 5 mgm. per cent respectively.

Just prior to the onset of pupation, the reducing value of *Gastrophilus* blood rapidly increases to more than 500 mgm. per cent, although the fructose remains at its normal level. As pupation advances, the fructose content rapidly decreases, as shown in the following table:

Age of pupa, in days	1–2 (pre-pupa)	2–3	6–7	10–11
Total reducing value in mgm. %	375	196·5	186	202·5
Fructose content in mgm. %	171·2	100·5	31·6	21·7

Yeast fermentation tests have demonstrated that the whole of the fermentable sugar is still fructose, and that, therefore, by the tenth day of pupation, when the developing fly is externally almost fully formed, glucose has not increased at the expense of fructose.

It should be pointed out that these experiments were performed from March onwards, when the *Gastrophilus* larva is accumulating large stores of fat, and its glycogen reserves are being depleted[5,9]. The possible role of fructose in the intermediary metabolism of this change is to form the subject of further work.

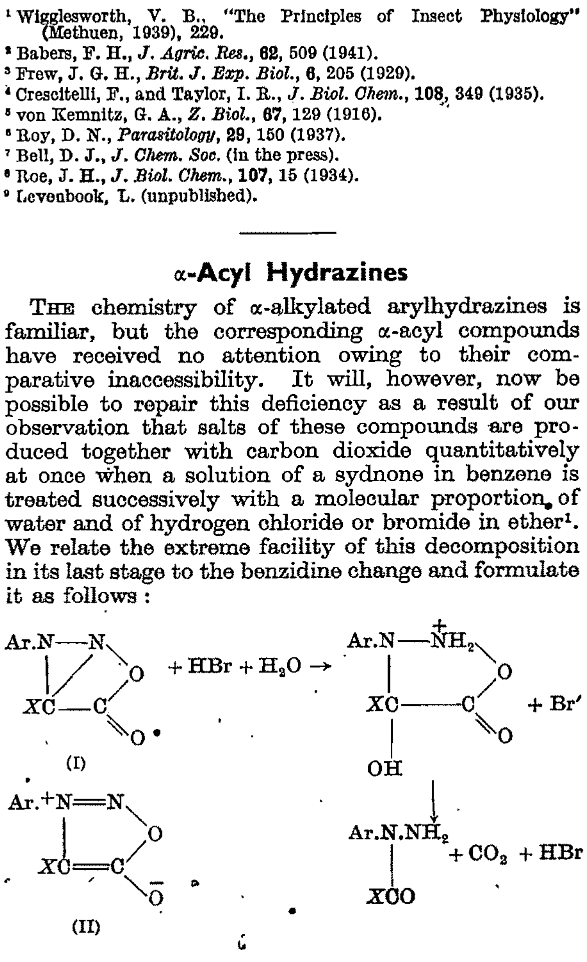
α-Acyl Hydrazines

THE chemistry of α-alkylated arylhydrazines is familiar, but the corresponding α-acyl compounds have received no attention owing to their comparative inaccessibility. It will, however, now be possible to repair this deficiency as a result of our observation that salts of these compounds are produced together with carbon dioxide quantitatively at once when a solution of a sydnone in benzene is treated successively with a molecular proportion of water and of hydrogen chloride or bromide in ether[1]. We relate the extreme facility of this decomposition in its last stage to the benzidine change and formulate it as follows:



It would appear very difficult to interpret these facts in terms of the formula (II) considered in earlier correspondence[2], although this latter accords with other evidence and with the immediate reduction of potassium permanganate in acetone. On the other hand, we have not observed phenolic reactivity of N-phenyl sydnone towards aldehydes or coupling agents, and we conclude that the sydnones exhibit intra-annular tautomerism between structures I and II.

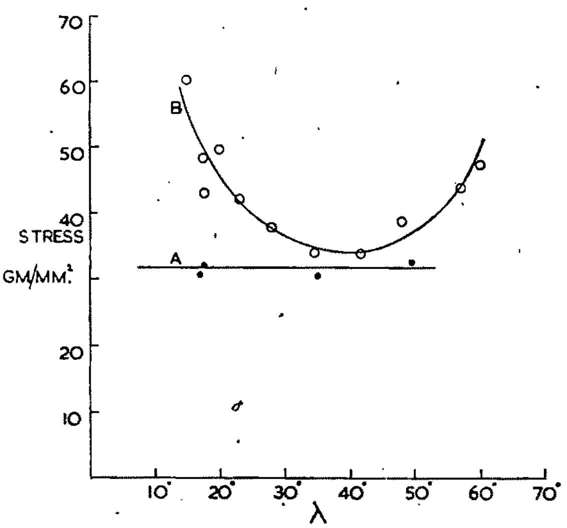
Thermal Hardening of Cadmium Crystals

THE phenomenon of thermal hardening was first observed by Orowan[1,2] in single crystals of chemically pure zinc. He noticed that, sometimes, zinc crystals, after resting for 24–48 hours at room temperature, showed no trace of plastic deformation with applied stresses as much as 30 per cent above the previously determined critical yield stress. The crystal might remain for several minutes under such a high load without yielding; then extension would suddenly occur, and the yield stress fall, almost immediately, to the normal value originally observed.

Recent work in this Laboratory with single crystals made from spectroscopically pure cadmium has shown that the phenomenon is not a rare one, but occurs with every crystal used. These cadmium crystals show appreciable hardening (increase of yield stress by 5 per cent over the previously determined yield stress) in times as short as 4–5 min. at room temperature. Preliminary experiments showed that, for the temperature range 20–100° C., the time of annealing necessary to produce a given degree of thermal hardening decreases by a factor of between 2 and 3 for every 10° C. rise in temperature, and even with those crystals slowest to harden (see below) the process was always complete after annealing at 200° C. for 30 min. After this treatment the yield stress had been raised to a limiting maximum value, and this was therefore adopted as standard treatment in later experiments.

Two other factors were also found to influence markedly the rate of thermal hardening, namely, orientation and pre-straining of the crystal. The period of annealing was found to be a maximum for crystals where λ (the angle between the direction of the applied stress and the glide direction) lay between 30° and 50°. These figures could not be determined very accurately. The period of annealing was also found to increase rapidly with the amount of pre-strain impressed on the crystal, as is shown by the following figures. The 'hardening time' is the time needed, at room temperature, for the yield stress to rise 5 per cent above the previously determined critical shear stress.

Hardening time	Pre-strain
5 min.	0·1 per cent
40 ,,	3·8 ,,
140 ,,	11·0 ,,



After this preliminary work, further experiments were performed to determine how the value of the 'raised' yield stress varied with the orientation of the crystal, the annealing conditions being constant, that is, 200° C. for 30 min., and then cooling to room temperature, at which temperature the yield stress was determined.

The accompanying graph shows the variation, with orientation, of both the normal yield stress in shear (curve *A*), and also the 'raised' yield stress (curve *B*), for spectroscopically pure cadmium (99·999 per cent Hilger H.S. specification). As is to be expected, the normal yield stress is constant at 32 ± 1 gm./per mm.^{2}. The yield stress has also been determined for 'chemically pure' cadmium and found to be 60 ± 1 gm./mm.^{2}. These results are in good agreement with those of Andrade and Roscoe[3], who give corresponding values of 26 gm./mm.^{2} and 56 gm./mm.^{2}. The effect of very small amounts of impurity on the value of the critical shear stress has also been reported by Dehlinger and Gisen[4], who found that, in changing from 99·87 to 99·98 per cent aluminium, the yield stress falls from 145 gm./mm.^{3} to 85 gm./mm.^{2}.

The curves also show the striking fact that the magnitude of the thermal hardening is a minimum for crystals with the glide direction at an angle λ between 40° and 45° to the axis of the wire, and that with these crystals it is approximately zero. For angles of orientation on each side of the minimum, the 'raised' yield stress rises rapidly, the maximum so far observed being approximately 70 per cent above the normal value.

If it is assumed[1] that thermal hardening is due to the movement of dislocations out of the crystal or into positions where they cannot be moved easily by the applied stress, the effects of temperature, pre-strain, and impurities are easily understood. At higher temperatures, the movement of dislocations takes place more rapidly; greater pre-strain produces a higher density of dislocations which, by their mutual interaction, impede each other's movement[5]; and the presence of impurities leads to internal stresses which act as barriers to the movement of the dislocations and slows down the process of their elimination. The new fact of the dependence of thermal hardening on the orientation of the crystal, however, does not seem to be explicable on such general assumptions.

I would like to thank Dr. E. Orowan for helpful discussions, and the British Iron and Steel Research Association, under the auspices of which the work was done, for permission to publish this paper.

Surface Tension and Detergency

THE surface tension of an aqueous solution has long been recognized as one of the more important physical properties controlling its wetting and detergent powers, though early attempts to correlate these powers with equilibrium surface tension met with limited success. It is becoming generally appreciated that factors other than solute concentration influence surface tension, and that the condition of the surface must also be taken into account. Thus, the surface age involved in many detergent processes does not exceed a few seconds, and much of this time may be required for the establishment of diffusion equilibrium. For dilute solutions of long-chain compounds the operative dynamic tension may vary over a range of 40 dynes/cm., and acknowledgment of the time required for surface equilibrium is clearly essential. A further factor, the change in equilibrium surface tension which occurs during change in area of a soluble film, has not previously been considered, but may prove to have considerable significance.

In very dilute solutions, the decrease in tension is proportional to solute concentration, and the Gibbs adsorption equation simplifies to the linear $\gamma - \Gamma$ relation $\gamma = \gamma_0 - RT\Gamma$ typical of a gaseous film. Lateral cohesion, or repulsion between adsorbed molecules at higher concentrations, necessitates the introduction of correction factors; but these direct equations imply that the surface tension is dependent only on the surface excess Γ so long as the surface is stationary (that is, of constant area). However, recent experiments[1] have shown that the surface tension equivalent to a given surface excess per unit area of a long-chain adsorbate may be varied by as much as 10 dynes/cm. during expansion of the surface. If the adsorbed carbon chain is sufficiently long, the distribution of the forces between molecules at or near the surface (and thus the free surface energy) will depend upon the mean position of orientation of the adsorbed molecules. This orientation is likely to differ at stationary and expanding surfaces, and it is significant that the expansion effect is not apparent for short-chain solutes. Again, on contraction of a soluble film the migration of long-chain molecules away from the surface appears to take an appreciable time, so that a fresh contracting surface may contain an amount of adsorbed material in excess of the equilibrium amount.

Therefore, the surface tension of a solution, previously regarded as a function of bulk concentration and time only, must now be considered as subject to changes in area also, and the possible types of air–water interface may be subdivided as follows:

Dynamic stationary (1) → Equilibrium stationary (2) → Aged stationary (3)
Dynamic expanding (4)
Equilibrium expanding (5)
Dynamic contracting (6) → Equilibrium contracting (7).

The term 'dynamic' is restricted, as already suggested in *Nature*[2], to surfaces at which the initial surface excess is in the process of accumulating. The term 'equilibrium' implies that the initial diffusion required in the accumulation of the surface excess has been completed, though secondary diffusion processes resulting from changes in surface area may still be operative. Arrows indicate those surface types which pass from one to another with time; (4) can only pass into (5) by increasing the solute concentration. A similar range of surface types exists for liquid–liquid interfaces, though (3) is not well characterized.

The fresh surfaces operative in detergent processes are frequently expanding or contracting, and may fall into any one, or several, of the above types (except (3)). For a given solution, the surface tensions corresponding to these different surface types vary widely, and it appears essential that the type of surface involved should be determined before any successful correlation between surface tension and detergent power can be achieved.

Optical Rotatory Power and Atomic Dimension

IN a recent paper by Brauns[1], an attempt is made to relate the differences in optical rotatory power of the respective alkyl halides and the differences in atomic dimensions of the halogens. The ratio of differences in specific rotation (*D* line) of the 2-halogenopentanes were found to be (Br, 41·6 — 42·6, Cl) : (I, 46·68 — 41·6, Br), that is, — 0·86 : + 5·08. Atomic dimension differences require (Br — Cl) : (I — Br) = 17·1 : 21·4, and on this basis the bromide should have a larger rotation than the chloride.

Whereas previous observations[2] mentioned by Brauns had led to the conclusion that 2-chloro-octane, $[\alpha]_D^{20^\circ}$ 35·8°, had a higher rotation than the bromide (best estimated maximum, $[\alpha]_D^{20^\circ}$ 33·8°), he now obtains 2-bromo-octane having $[\alpha]_D^{20^\circ}$ 40·6°, and providing a ratio of 17·1 : 30·3 for (Br — Cl) : (I — Br). In this observation he was preceded by Gerrard[3].

This question of maximum rotation of halides becomes even more interesting in the example of phenylmethylcarbinol. Whereas $[\alpha]_D$ 50·6° for 1-chloro-1-phenylethane[4] was for some time accepted as being near the maximum rotation, the rotatory power of the bromide being even less than this, Gerrard[5] obtained a specimen of the chloride having $[\alpha]_D^{16^\circ}$ 93·5°, by the interaction of the carbinol and phosphorus oxychloride in the presence of pyridine, and the bromide having $\alpha_D^{18^\circ}$ 131·4° ($l = 1$) by means of phosphorus tribromide and pyridine.

In a further examination of this subject, we are employing phosphorus oxybromide, the uses of which, in organic chemistry, do not appear to have been investigated. This reagent in the presence of pyridine gave rise to 1-bromo-1-phenylethane with $\alpha_D^{17°} + 125{\cdot}2°$ ($l = 1$), from ROH, $\alpha_D - 44{\cdot}0°$, and 1-bromo-1-phenylpropane with $\alpha_D^{16°} + 174{\cdot}2°$ ($l = 1$), from ROH, $\alpha_D^{10°} - 26{\cdot}4°$.

From the flattening of their rotation – reaction-temperature curves, Levene and Rothen[6] conclude that the maximum values of the molecular rotations of these bromides are respectively $[M]_D$ 90° and $[M]_D$ 140° (in benzene). Since Arcus[7] used these values to represent the experimental curves of Levene and Rothen in terms of percentage optical purity and the contributions of stated mechanisms to the rotation of the product obtained at the different temperatures, and since our values for $[M]$ (benzene) are nearly twice these, it follows that Arcus' curves and argument should be reconsidered.

Preparation of Colourless Carborundum

In a paper to Section I of the Eleventh International Congress of Pure and Applied Chemistry, J. T. Kendall and D. Yeo described the preparation of pure silicon carbide by passing the vapours of silicon-organic compounds over a heated carbon filament; the product they obtained was bright yellow in colour and it was not found possible to prepare colourless specimens by this method. On theoretical grounds it would be expected that pure silicon carbide should be colourless and, according to H. Moissan[1], carborundum free from traces of iron is without colour; he obtained almost colourless, prismatic needles of carbon silicide by allowing the vapours of carbon and silicon to react with one another. In view of current ideas on the part played by impurities in determining the electrical properties of semi-conductors, it is of interest to record another and simpler method by which colourless carborundum can be prepared.

The following observations were made during a study of the deposition of carbon from the gas phase on fused silica. The experiments were carried out in a long vitreosil tube 0·8 in. internal diameter, heated electrically. Inside this tube was another vitreosil tube, 6 in. long, 0·4 in. internal and 0·6 in. external diameter, provided with lugs so that an annulus was left between the two tubes. The temperature was measured by means of a Pt/PtRh thermocouple, surrounded by a vitreosil sheath, situated axially in the tube. Ethylene, saturated with water vapour, was passed through this apparatus heated to 1,200° C. at a constant rate of twenty-five litres (measured at room temperature) an hour. In one experiment, which had lasted several hours, in addition to the carbon deposit there was formed on the centre part of the outer surface of the inner silica tube a white, fluffy, mould-like growth. An X-ray powder photograph showed this to be cubic carborundum; although only microcrystalline, the back reflexions in the powder photograph were sharp and resolved. In appearance it was quite unlike the greenish-yellow cubic variety formed when carbon reacts with silica at higher temperatures; it had a soft texture and readily gave an extruded rod for X-ray examination when mixed with a little dilute gum arabic solution. First attempts to repeat this preparation were unsuccessful, possibly because the surface of the silica tube must be in a specially active condition. At a somewhat higher temperature (1,300° C.), however, it was found possible to repeat the formation of this white form of cubic carborundum.

A Volatile Compound of Copper

Körösy[1] has recently reported that copper formate decomposes when heated, evolving a small amount of a volatile copper compound. I encountered a similar phenomenon when gently igniting a deposit from a copper rectifying column, the deposit containing cupric acetate. According to Angel and Harcourt[2] the formation of a white sublimate of cuprous acetate on heating cupric acetate was first observed so long ago as 1773 by Lassone[3]. The formation of such volatile compounds may result in low values for the copper content of such materials as vinegar when dry-ashing methods are used in their analysis.

A Crystalline Principle from *Ammi majus* L.

Ammi majus L.[1] (Umbelliferæ) is an annual herbaceous plant which is widely spread in the Nile delta region and closely resembles *Ammi visnaga* L. The fruits of *Ammi majus* are taken internally by the public to cure leukoderma.

The powdered fruits of *Ammi majus*, collected in May, were extracted by hot petroleum ether (b.p. 60–70°) and the extract kept in the ice chest overnight, when a crystalline greenish mass separated, from which a colourless crystalline principle m.p. 148° was isolated, and for which the name 'ammoidin' is proposed (I. R. F. and H. A.). The crystalline substance was investigated chemically (A. S. and A. S.). It is easily soluble in chloroform and benzol, and contains neither active hydrogen nor acetyl group. The methoxyl test is positive and the substance does not react with diazomethane. It seems not impossible that the substance is related to ‘kellin’[2], which is used in the treatment of angina and bronchial asthma[3].

Further work from the pharmacognostical and chemical sides is in progress.

An Apparatus for Preparative Electrophoresis

A considerable number of suggestions have been made[1] of arrangements for the separation of ionized substances of different mobilities in an electric field, involving, for example, (1) diaphragm cells with three or more compartments[2], (2) a series of beakers connected by inverted U-tubes[3], (3) tubes filled with sintered glass[4], (4) slabs of silica gel[5], (5) modifications of the Tiselius apparatus which permit the withdrawal of liquid from any section of the advancing front[6].

(1) and (2) suffer from the disadvantage that convective and electro-endosmotic streaming occur in the compartments, so that the useful separative process is confined to the membranes or narrow tubes; (3) has an unduly high resistance; (4) has been successfully employed for comparatively small peptides. It is anticipated that the gel may hinder the free migration of larger molecules; and the problems of detection within the jelly and separation from it become formidable when only a few milligrams of material are available. The Tiselius apparatus is essentially one for the analysis of the moving fronts, and though samples can be withdrawn for analysis, it does not permit a complete separation of the components of a mixture.

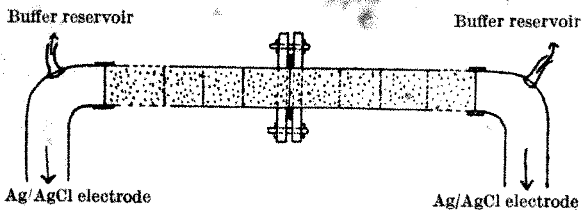

Fig. 1. Preparative electrophoresis apparatus

After a number of trials of other types, we have developed a simple apparatus which gives satisfactory results so far as it has been tested (Fig. 1). Migration is made to occur down a tube of thin polystyrene plastic material, about an inch in diameter and a metre long, which is fairly loosely filled with asbestos fibre of the type usually used in Gooch crucibles. This does not greatly increase the resistance of the column when filled with the buffer solution, and effectively prevents convective spreading. The asbestos is divided into sections by filter paper barriers at 1-inch intervals. These permit the wads of asbestos to be separated with ease when removed from the tubes. The tube is divided into two halves, fitted with plastic end-pieces, which enable them to be clamped together, making with a rubber washer a water-tight junction. The tube can be divided into as many sections as may be convenient, and sections can be removed or added during the electrolysis without disturbing the remainder. The tube is cooled by a water sprinkler placed above it.

The solution to be examined (about 5 c.c. in this apparatus) is mopped up with dry asbestos and introduced into the tube at the middle join. It is important that the solution and the buffer present in the rest of the column should be at the same *p*H and have approximately equal specific conductances; otherwise migration anomalies occur. The electrodes are of silver – silver chloride in concentrated sodium chloride similar to those used with the Tiselius apparatus. They are completely closed, so that no transport of the solvent occurs through the column.

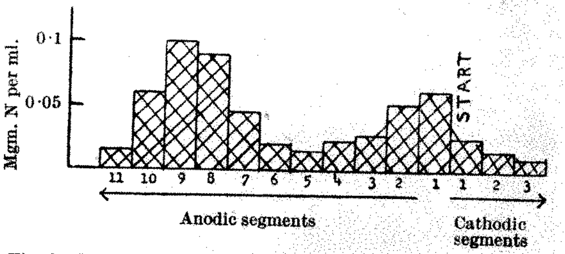

Fig. 2. Electrophoretic separation of glycine and glycylglycine at *p*H 9·3

In tests with coloured substances such as dinitrophenylglycine and coloured indicators it was found that the asbestos effectively prevents the convective dispersion of the coloured ions, which move down the tube without undue spreading. The asbestos wads are blown out of the tube by air pressure or pulled out by tongs after the experiment. It is a simple matter to squeeze the liquid contents of each segment into a test tube for analysis. Fig. 2 shows the analysis of the segments after electrolysis of a mixture of glycine and glycylglycine at *p*H 9·3 for 24 hours with a potential difference of 250 volts between the electrodes (approximately 2 volts per cm. in tube). It is clear that a good separation has been obtained, the fraction which has migrated towards the anode at this *p*H being glycylglycine. A more detailed account will be given elsewhere.

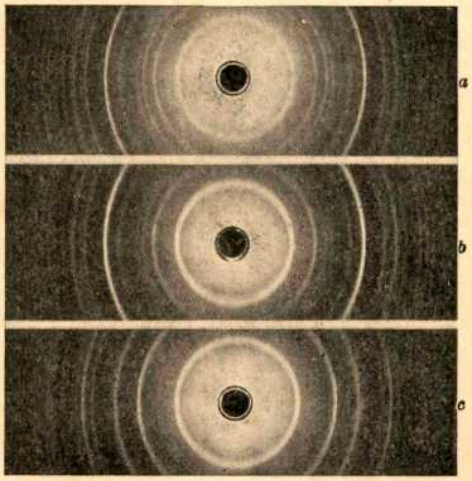
Identification of a Calculus from a Hippopotamus

During a recent visit to Nairobi, one of us (K. P. O.) secured, for purposes of determination, a fragment of a brown calculus of rather unusual origin which is preserved in the Kenya Game Department. Captain A. T. A. Ritchie, chief game warden, said that according to report this 'stone' was found in a hippopotamus killed on the Tana River some years ago. It was cut out of the animal by a native skinner, whose employer had passed it to Captain Ritchie. The location of the calculus in the animal was not recorded.



X-RAY POWDER PHOTOGRAPHS OF (a), ARTIFICIALLY PREPARED $CaC_2O_4.2H_2O$; b, POWDERED HIPPOPOTAMUS CALCULUS, $CaC_2O_4.2H_2O$; c, WHEWELLITE, BURGK, DRESDEN, SAXONY

The 'stone' is a flattened irregular ovoid with a smooth surface and, according to Mrs. M. D. Leakey, originally measured about 8 cm. × 6 cm. × 4 cm. It has been broken away on one side to a depth of nearly a centimetre, revealing a concentrically laminated structure and an apparently uniform composition. The fragment brought back to England is made up of concentric zones not more than 10 μ thick and readily cleaves into layers about 1 mm. thick. Chemical tests and X-ray powder photographs show that it is identical with tetragonal hydrated calcium oxalate, $CaC_2O_4.2H_2O$ [a 12·40, c 7·37 A.][1], and not with whewellite, the monoclinic monohydrate. Examination in polarized light reveals a minutely fibrous structure with fibre axis perpendicular to the plane of zoning, and X-ray diffraction photographs of stationary sections confirm that the fibre axis is c [001] but reveal that the orientation of the fibres across the plane of zoning is far from perfect. Moreover, there is no orientation of the [100] axes in the plane of zoning. The optical examination and X-ray photographs show that the layers are uniform in composition and crystal size, the length of each fibre not exceeding 10 μ and the cross-section being of the order of 1 μ.

Tetragonal calcium oxalate (weddellite) is very rare as a mineral but has been reported by two of us (F. A. B., M. H. H.) from one locality in the very deep water of the Weddell Sea, and its occurrence as minute 'envelope' crystals in plants and human urine is well known. Renal calculi from the human bladder are, however, usually of mixed composition, and those examined by us in 1936 were essentially fine-grained calcium carbonate-phosphate, similar to the mineral dahllite (carbonate-apatite), studded with large crystals (2–3 mm. across) of tetragonal calcium oxalate.

Structures Produced in Clays by Electric Potentials and their Relation to Natural Structures

If an electric potential is applied by means of two electrodes to a remoulded soil containing a proportion of particles of colloidal size, such as London clay, the soil develops a structure which is similar in appearance to that of the clay in its natural state. This phenomenon was observed by me in 1931 on a great variety of fine-grained soils. In recent investigations carried out on London clay and Wyoming bentonite, I found that the electro-osmotic transport of pore water towards the cathode results in the formation of cracks in the soil around and between the electrodes, the pattern of the cracks following the equipotential lines. These cracks, which are filled with free water, become more widely spaced with increasing distance from point electrodes. Originating from these basic cracks an irregular pattern of additional fissures is formed. When the soil becomes consolidated, as, for example, by continued electro-osmotic drainage or drying, the fissures

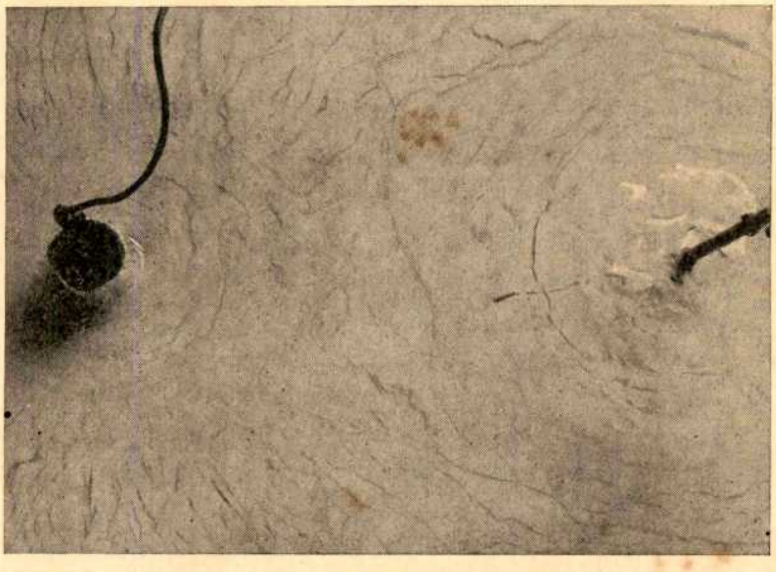

Fig. 1

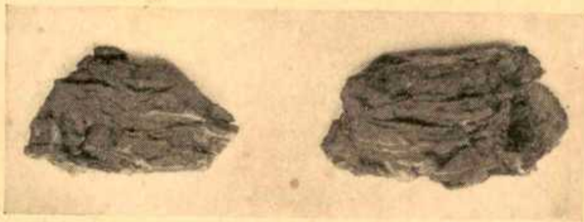

Fig. 2

and cracks close up but the structure remains even in the completely dry state and is readily revealed on breaking up the soil. Fig. 1 shows such a pattern in a gel of 2 per cent by dry weight of Wyoming bentonite, after a potential gradient of 0·2 volts per cm. was applied for forty hours. Surrounding the copper cathode (the thick electrode) concentric fissures in the process of formation can be seen.

Fig. 2 shows the laminated structure produced in a sample of what was originally uniformly remoulded London clay after treatment with a potential of 0·5 volt per cm. over a period of three months. The laminations follow the equipotential surfaces.

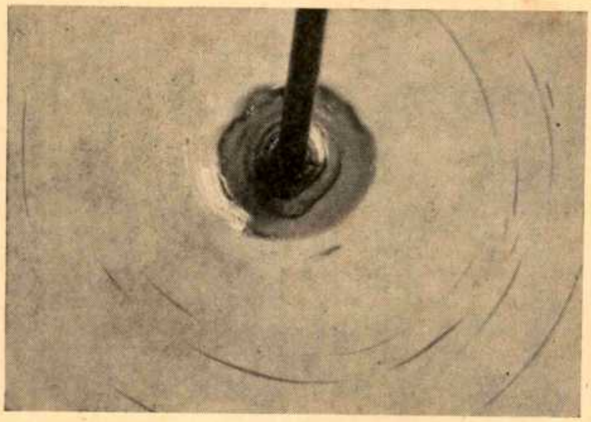

Fig. 3

Apart from the visible laminations in Fig. 2 the sample exhibits a random fissured structure with polished walls similar in appearance to the well-known fissures found in most old natural clays, for example, London clay, which were laid down by sedimentation. The greater the colloidal content of the soil, the more distinctly are the fissures developed, and this seems to conform to Nature where the more colloidal clays generally exhibit better developed fissures.

While the spaces between the individual laminations (equipotential lines) are similar at both electrodes, visible cracks do not always appear at the anode. Differences arise from the use of different metal anodes.

When an iron anode is used, an equipotential pattern of brown colour tones is produced from the anode, and with an aluminium anode in a bentonite suspension a practically colourless pattern develops, which may be seen in the form of slight ripples when the surface of the bentonite is viewed obliquely.

Under the microscope fine cracks forming an equipotential pattern are visible. Without exception, the anodic pattern (Fig. 3) resembles the well-known phenomenon of Liesegang rings[1].

It will be recalled that Liesegang in his experiments noticed that there was a marked concentration of water ahead of his rings. I have checked in a number of tests that the formation of Liesegang rings is associated with a considerable transport of pore water from the spot centre. The similarity between this and the anodic action in an external field suggests that the periodicity of precipitation may be conditioned by the development of cracks in the gel.

I feel that the concept of a water movement similar to the electro-osmosis arising from anodic action may have a useful application in connexion with many of the unsolved problems associated with the phenomena of rhythmic ring formation such as those which occur in flint and agate, and possibly in the pathological growth of concretions in man and animals.

The similarity between the laminations of Fig. 2 and those found in certain clay deposits, for example, varved clays, suggests an alternative explanation of the formation of varves to that given by De Geer[2] and his collaborators and pupils. The electric streaming potential originating from the natural consolidation of clay during deposition, or potentials arising from other external sources, could, it is suggested, produce laminations in clay in a similar way to those produced artificially in the laboratory.

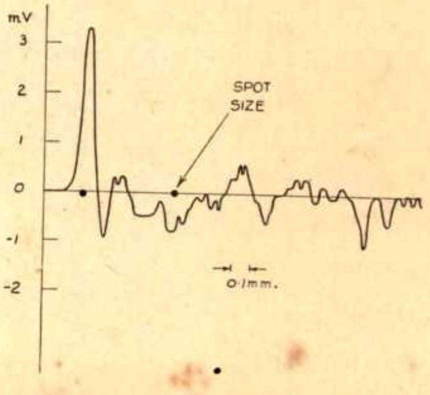
Occurrence of Random Photovoltaic Barriers in Photoconductive Layers

IN two previous communications[1,2] the photoconductive properties of lead sulphide layers and a new photovoltaic effect were described. The latter effect is essentially a property of the semi-conductor and is not associated with the electrodes. A theory of the effect was outlined which attributed the photo-e.m.f. to the barrier between regions of excess and defect semi-conductors. It was further postulated that, in an apparently homogeneous photoconductive layer showing no external photo-e.m.f., there existed regions distributed at random which were predominantly either excess or defect semi-conductors. The photoconductive properties of the layer were also attributed to the barriers between these regions. Experimental evidence has now been obtained to justify this assumption.

Photoconductive layers have been scanned by a small spot of light, 30 microns in diameter, formed



by focusing, with a microscope objective, an image of a two-watt Western Union concentrated arc source. The photo-e.m.f. was measured using an electrometer triode. In every case a photo-e.m.f. was observed varying in magnitude and sign from point to point of the layer. The accompanying figure shows the typical variations for 2 mm. of a photoconductive layer of lead sulphide of about 1 micron thickness and 20 × 1 mm. area.

Since the theory is applicable to any substance which may exist as an excess and defect semiconductor, it was thought that the presence of photovoltaic barriers should be observed in photoconductive layers of substances other than lead sulphide. We are able to report preliminary results on layers of selenium which support the above conclusions. The photovoltaic effects observed in this case show, in general, the same magnitude and type of variation as those described for lead sulphide layers.

We have to thank Mr. J. S. Preston, of the National Physical Laboratory, for the preparation of the layers of selenium.

Radiant Temperatures of Walls in North–South and East–West Rooms

IN an investigation of indoor climate conditions initiated by the Indoor Climate Committee of the Meteorological Research Council in Palestine in the autumn of 1946 the mean radiant temperatures of walls of dwelling-rooms were (among other factors of the indoor climate) measured by means of the globe thermometer of Vernon. The observations were taken in two newly built houses of similar design, building materials, etc. The only difference between the two houses was in the orientation of the main fronts (longer walls): the main fronts of one house faced north and south, while those of the second one faced east and west. The actual observations were taken on the first floors of these (three-storied) houses. To be more precise:

(1) In the north–south house in a south room, whereby we mean a room (*a*) with a window on its south side; (*b*) communicating on its north side to another room with a window opening to north (the door between the two rooms was kept open during the whole period of observations); (*c*) on the east and west of the room there were other apartments, thus eliminating the direct climatic influence of the east and west fronts of the house.

(2) In the east–west house in an east room, whereby we mean a room the description of which will be obtained from that of the foregoing by substituting east for south and west for north.

The result of the observations was that the mean radiant temperatures of the walls in the east room have a double maximum during the day, one between 9 and 10 a.m. (local time) and the second one between 5 and 6 p.m. This would correspond to a maximum of irradiation by the sun of the east wall in the morning and the west wall in the afternoon. The south room has a single maximum occurring between 2 and 3 p.m.

The morning radiant temperature maximum of the walls in the east room is about 2½° C., the afternoon maximum about 1¼° C. higher than the instantaneous value of the mean radiant temperature in the south room. On the other hand, the single maximum in the south room is not above the instantaneous value in the east room. The mean radiant temperature of the south room is always below that of the east room.

If the windows be kept shut during the day, the room air temperature in the east room will have a slight local maximum at about 10 a.m. (the observations were taken at the height 1·20 m. above floor), followed by a decrease, and afterwards a fresh and more gradual rise to the afternoon maximum.

The significance of the above is clear for the better orientation of houses in a country with a long and warm summer—a thesis that has been advocated by the above Committee.

I am indebted to the Committee for permission to publish this note.

Technique of the Analysis of Variance

I AM afraid I disagree with Dr. Vajda's comments[1] on the analysis of variance technique appropriate to two-way tables with unequal frequencies in the different sub-classes. As I pointed out in the paper referred to[2], the expressions for the efficient estimates of the 'main' effects of the two variables are different according as interactions are assumed to exist or not. If interaction is assumed, the efficient estimate for the first variable in a 2 × 2 table, using Vajda's notation, is

$$a_1 = \tfrac{1}{2}\{(x_{11} - x_{21}) + (x_{12} - x_{22})\}.$$

If there is no interaction, it is

$$a_2 = \left\{\frac{n_{11}n_{21}}{n_{11} + n_{21}}(x_{11} - x_{21}) + \frac{n_{12}n_{22}}{n_{12} + n_{22}}(x_{12} - x_{22})\right\} \Big/ \left(\frac{n_{11}n_{21}}{n_{11} + n_{21}} + \frac{n_{12}n_{22}}{n_{12} + n_{22}}\right).$$

It is this latter expression that I derived by the method of fitting constants. (In the case of a 2 × 2 table it can, in fact, be written down directly by considering the variances of $x_{11} - x_{21}$ and $x_{12} - x_{22}$.) The expression for a_1 can, of course, also be derived by fitting constants, including a constant for interaction, though its form is obvious.

If all the sub-class frequencies are equal, the two estimates are identical, and this accounts for the formal simplicity of the analysis of tables with equal sub-class frequencies.

Snedecor[3] made an important further contribution to the subject when he pointed out that this formal simplicity is retained in the case of tables with proportionate sub-class frequencies ($n_{ij} = u_i v_j$), provided the main effect of each variable is re-defined as its average effect over the frequencies actually observed of the other variable instead of its average over equal frequencies of the other variable. In this case the estimate of the first variable is

$$a_3 = \frac{v_1}{v_1 + v_2}(x_{11} - x_{21}) + \frac{v_2}{v_1 + v_2}(x_{12} - x_{22}).$$

It will be noted that a_2 is identical with a_3 when the frequencies are proportionate.

The practical importance of this is that in the frequently occurring case when the observed frequencies, though very unequal, are nearly proportionate, an analysis can be made by the substitution of proportionate frequencies. This will not do any violence to the data, and will result in an immense reduction in computational labour. The estimates of the main effects so obtained are the same whether interactions exist or not; and, if interactions cannot be assumed negligible, are considerably more precise than those (a_1 above) obtained with the alternative definition of main effects.

There is consequently no logical inconsistency in the use of proportionate frequencies. If interactions exist, the magnitude of the main effects depends on the way in which they are defined, and the statistician must, of course, be clear what is implied. Inasmuch as the frequencies actually obtained are likely to be similar to those generally occurring in the type of material under consideration, the definition of the main effects implied by the use of proportionate frequencies is usually more appropriate in practice than that based on equal frequencies.

In conclusion, it may be noted that Dr. Vajda's first expression for the mean square gives the test of significance for a_1. His second expression gives the test of significance for a_3 (or a_2) when the frequencies are, in fact, proportionate; but in the more general form in which he has given it, it gives the test of significance for the estimate that would be obtained when the effect of the other variable and its interaction were both assumed negligible. It therefore has no relevance to the present argument.

Nomogram for the Tetrachoric Correlation Coefficient

ONE of the most frequently used measures of association in psychology, and even in other biological sciences, is the tetrachoric correlation coefficient. Unfortunately, the computing of r_{tet} from the standard formula is extremely laborious, and the value of some aid to this end has been recognized from the earliest days. This has become more important than ever, when correlations are prepared in hundreds for one factor analysis. The earliest of the devices for computing measures of association is the *ABAC* of Burt, which consists of a family of curves on one graph[1]. Vernon has four such graphs[2]. The best known of such aids are the computing diagrams of Thurstone[3]. There are forty-six such diagrams, each consisting of a family of curves. They are quite simple to read when working to two decimal places; but this can lead to considerable inaccuracy, and three places involves interpolating between two diagrams, with four readings each, a very time-consuming procedure.

It was considered desirable to attempt the construction of a nomogram for the tetrachoric correlation coefficient, which would have the advantage of being easy to read, and of being contained in only one diagram.

The equation for the true coefficient is impracticable for this purpose, but it was found that the empirical formula developed by Karl Pearson was eminently satisfactory[4]. This is $r_{\text{tet}} = \sin\left(\frac{\pi}{2}\cdot\frac{\sqrt{ad}-\sqrt{bc}}{\sqrt{ad}+\sqrt{bc}}\right)$,

b	a	$a+b$
d	c	$c+d$
$b+d$	$a+c$	N

where a, b, c and d are the cell frequencies. This converts into $r = \cos\left(\pi\cdot\frac{\sqrt{bc}}{\sqrt{ad}+\sqrt{bc}}\right)$. If r is read in degrees (and appropriately scaled in the nomogram), the formula can be manipulated into $\sqrt{ad} = \sqrt{bc}\,.\left(\frac{180-r^\circ}{r^\circ}\right)$.

It is impossible to design a nomogram if the cell frequencies are kept in their original state, or converted into probabilities totalling unity. If, however, the cell frequencies are divided by one of them, for example, c, the equation becomes $\sqrt{AD} = \sqrt{B}\,.\left(\frac{180-r^\circ}{r^\circ}\right)$, where $A = a/c$, $B = b/c$, $D = d/c$ and $C = c/c = 1$. This eliminates the non-independent variable in the only way suitable for the present purpose.

This equation can be used for the construction of a nomogram in two ways. Taking logarithms:

$$\log A + \log D = \log B + 2\,.\log\left(\frac{180-r}{r}\right),$$

from which the two following determinants are obtained:

$$\begin{vmatrix} -1 & \log A & 1 \\ 0 & \tfrac{1}{2}R & 1 \\ 1 & \log D & 1 \end{vmatrix} = 0 \qquad \begin{vmatrix} -1 & \log B & 1 \\ 0 & \tfrac{1}{2}R & 1 \\ 1 & 2\log\left(\frac{180-r}{r}\right) & 1 \end{vmatrix} = 0$$

where R stands for a reference line

This nomogram consists of three parallel lines, the first being a logarithmic scale for A and D, the third a logarithmic scale of the same size for D, and of twice the size for $\left(\frac{180-r}{r}\right)$, which is then re-scaled for $\cos r^\circ$, and the second is a reference line halfway between. To read it, a line is drawn between A and D, and the point of intersection with the reference line joined to B and prolonged to r.

A more compact nomogram in the shape of a circle can be constructed by deriving from the equation as it stands the two determinants

$$\begin{vmatrix} \frac{A}{A+1} & \frac{\sqrt{A}}{A+1} & 1 \\ \frac{1}{1+R^2} & \frac{-R}{1+R^2} & 1 \\ \frac{1}{1+\sqrt{D}} & 0 & 1 \end{vmatrix} = 0 \qquad \begin{vmatrix} \frac{B}{B+1} & \frac{\sqrt{B}}{B+1} & 1 \\ \frac{1}{1+R^2} & \frac{-R}{1+R^2} & 1 \\ \frac{r}{180} & 0 & 1 \end{vmatrix} = 0$$

The upper half of the circumference is scaled for A and B, and the horizontal diameter for D and $\cos r^\circ$. The lower half of the circumference forms the reference line. The nomogram is read by joining A and D and prolonging the line to the circumference; the point of intersection is joined to B, and r read off. There are other ways of reading the nomograms, but this is the simplest for routine use. Other varieties of nomogram can be designed, if this method of eliminating one of the variables is used, for example, hexagonal and polar, but the two described are the simplest in use.

Feeding Mechanisms of *Chironomus* Larvæ

THE large, hæmoglobin-bearing larvæ of the genus *Chironomus*, commonly known as bloodworms, are the most abundant and widespread members of the bottom mud communities in ponds and lakes, but owing to the obscurity of the medium in which they live little is known about their behaviour. The larvæ live in U-shaped tubes through which an intermittent irrigation current is maintained[1], and are stated to feed on the organic mud around them, eating part of the walls of their burrows or feeding off the surface of the mud[2]. Alsterberg[3], however, considered them to be largely plankton feeders, eating algæ brought in by the irrigation current and trapped by the tube walls or the spines of the anterior proleg. But details of their feeding mechanism or respiratory behaviour are unknown. Accordingly, I have watched the behaviour of larvæ of *Chironomus plumosus* L. under various conditions.

Glass U-tubes, resembling in proportions those which the larvæ construct in Nature, and perforating a small celluloid platform holding a thin layer of mud (Fig. 1), housed the larvæ. Platform and tubes were placed in water in small glass aquaria. In the course of the observations a feeding method was discovered which has not previously been described. The larvæ were seen to feed largely on suspended matter filtered out of a stream of water set up through the tube by their own activity. This feeding is carried out as follows. Maintaining its position in the tube by means of firmly anchored posterior prolegs, the larva performs a number of rotatory movements of the anterior region of the body, the head describing complete circles of alternating direction round the wall of the tube. While these movements are being made the anterior proleg draws out strands of salivary secretion by rapid approach to, and withdrawal from, the mouthparts, the strands being attached to the walls of the tube and stretched across its lumen to form a loose, saucer-shaped sheet. The larva then withdraws a few millimetres down the tube, dragging with it a salivary thread from the middle of the sheet, which is thus pulled out to form a shallow conical net (Fig. 2). Attached to the thread with its mouthparts, it begins violent antero-posterior undulations of the body with a frequency of about two per second. These have the effect of producing a current of water through the tube, and particles suspended in the water are caught by the conical net. The larva next straightens its body and rapidly eats the cone with the suspended matter on it; it then at once spins another web. The whole process is remarkably rapid, successive cones being formed and eaten at the rate of one every 1½–2 min. Approximately half the time is spent in undulating and the other half in eating and making the net. Although these time intervals vary for individual larvæ their repetition is very regular, and the whole performance forms a very stereotyped behaviour pattern which may persist for an hour or more with a regularity uninfluenced by the degree of loading of the net. More rarely, larvæ omit the net-spinning process and, instead, between the periods of irrigation, scrape the walls of their tubes which, being lined with salivary secretion, also trap particles. Very occasionally they feed from the mud surface; in doing this, they extend the body out of the tube entrance, retaining contact with it by means of the posterior prolegs, and spread a net of salivary secretion over the mud, which is then dragged down with its attached particles for consumption in the seclusion of the tube.

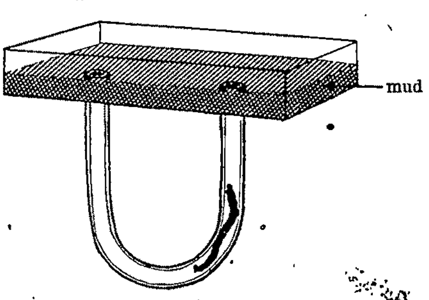

Fig. 1

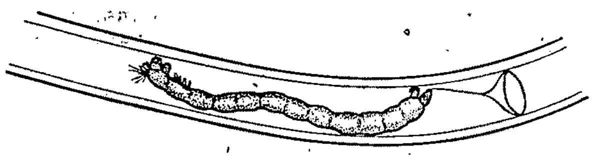

Fig. 2

The filtering method is, however, the commonest feeding mechanism in *C. plumosus* and resembles that of leaf-mining chironomids[2,4], except that in the latter the larva turns round after spinning the salivary cone, which is therefore posterior to the larva with the apex pointing away from the body. It also recalls the feeding mechanism of *Urechis caupo*, in which a long cone is secreted by the echiuroid worm and remains attached to the head during the irrigation of the U-shaped burrow[5]. In this case the cone is of mucus with pores of ultramicroscopic diameter and consequently high filtering efficiency[6].

I estimated the filtering powers of the nets of *Chironomus* by introducing into the inhalant current a suspension of carmine, and measuring the diameter of the particles before and after passing through the tube. The nets retain all particles bigger than $17\,\mu$ in diameter and most of those bigger than $12\,\mu$ in diameter, and would thus trap many planktonic organisms in addition to any particles of detritus, etc., temporarily suspended in the water as a result of agitation of the mud surface. The larvæ are unselective feeders in that they eat indiscriminately all particles attached to the net.

The observations have so far been confined to the larvæ of *Chironomus plumosus*, but it is likely that the other closely related species have the same habits. These larvæ provide one more example of a semi-sedentary animal solving the feeding problem by means of a filter mechanism.

NUCLEAR MAGNETIC RELAXATION

By N. BLOEMBERGEN, E. M. PURCELL
AND
R. V. POUND*
Harvard University, Cambridge, Massachusetts

THE method of nuclear paramagnetic resonance absorption[1] has been used to study the interaction of nuclei in solids, liquids, and gases with their environment. The two important quantities are the relaxation time T_1, describing the energy transfer from the nuclear spin system to the whole of the sample, representing the heat reservoir, and the interaction among the nuclei alone, which can be described by a spin-spin relaxation time T_2. From the theory of Waller[2] one can predict the relaxation time T_1 caused by interaction of the nuclei with the lattice vibrations. The time obtained is at least 10^4 times larger than the experimental values[3,4,5].

We shall show that another process, occurring in many substances, provides a 'local field spectrum'[5] intense enough to account for the observed relaxation times. Every nucleus experiences not only the constant field H_0, and the applied radio-frequency signal H_1 perpendicular to H_0, but also the local field produced by neighbouring nuclear moments and sometimes by small moments caused by molecular rotation, or in paramagnetic substances by large electronic moments. In liquids and gases, at least, the carriers of these neighbouring moments are not stationary but execute Brownian motion, changing position relative to the nucleus under consideration in a random fashion. Consequently, the local field $H(t)$ will be a random function with a correlation time τ_c, in which the relative position of the neighbours changes significantly. The intensity in the Fourier spectrum of a random function[6] is nearly constant for frequencies $\nu \ll 1/\tau_c$, and falls off rapidly for $\nu \gg 1/\tau_c$. If we assume the correlation function to be of the form,

$$\overline{H(t)H(t+\tau)} = \overline{H^2(t)}\, e^{-t/\tau_c},$$

we obtain for the intensity,

$$H^2(\nu)\Delta\nu = 4\overline{H^2(t)}\,\frac{\tau_c}{1+4\pi^2\nu^2\tau_c^2}\,\Delta\nu.$$

Now components of this spectrum perpendicular to H_0 at the Larmor frequency ($\nu_0 = 2\mu H_0/h$) of the nuclei will induce transitions just as does the applied radio-frequency signal. The transition probability for this process is (for spin $I = \frac{1}{2}$)

$$W = \frac{\mu^2}{4\hbar^2}\, H^2(\nu_0).$$

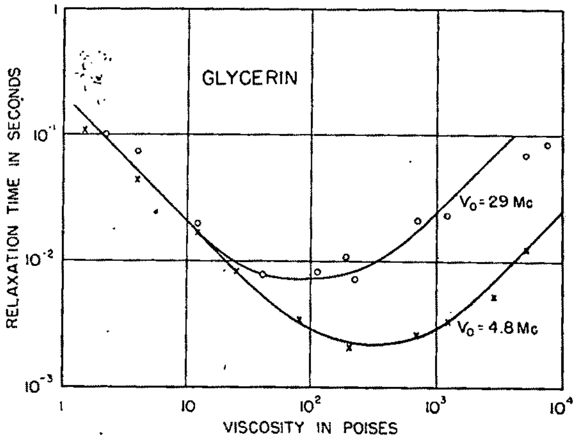
This process provides an interaction between nuclear spins and thermal motion with a relaxation time

$$T_1 = \frac{1}{2W} = \frac{\hbar^2}{\mu^2}\,\frac{1+4\pi^2\nu^2\tau_c^2}{\tau_c}\,\frac{1}{\overline{H^2(t)}}. \qquad (1)$$

$\overline{H^2(t)}$ could, in principle, be calculated for each substance, but will always be of the order $(\mu/r^3)^2$, where μ is the value of the neighbouring moment and r the internuclear distance. The correlation time τ_c can be estimated roughly, as in Debye's theory[7] of polar liquids, from the viscosity and the molecular dimensions. It is perhaps just as accurate in some cases to adopt the experimentally measured Debye time for reorientation of molecules under the influence of Brownian motion, although we must note that in the motion here discussed the neighbours of a molecule as well as the molecule itself are involved. A more refined theory would provide an appropriate distribution of relaxation times. In any event, we expect τ_c to be proportional to the viscosity. We now distinguish two cases: (*A*) $\tau_c \ll 1/\nu_0$, (*B*) $\tau_c \gg 1/\nu_0$. We see from (1) that in case (*A*) T_1 is inversely proportional to the viscosity. In case (*B*) T_1 is directly proportional to the viscosity. In most liquids we have case (*A*). The Debye relaxation in water, for example, occurs in 3×10^{-11} sec. at 20° C. Taking this as τ_c, we obtain with $\nu_0 = 29$ Mc./sec. a nuclear relaxation time of 5 sec., whereas the value of T_1 found in our experiments is 1·5 sec.

The relaxation time is measured by a saturation procedure. The power absorbed by the nuclei relative to the incident power is proportional to the surplus number of nuclei in the state of lower energy. This surplus will fall off rather abruptly if the incident power is increased sufficiently to raise the temperature of the system of nuclear spins.

The relaxation time in ethyl alcohol has been measured at 29 Mc./sec. and 4·8 Mc./sec., between + 60° C. and − 30° C. T_1 is found to be inversely proportional to the viscosity and independent of frequency (case *A*). The accompanying graph shows the relaxation time in glycerin for the same two frequencies and in the same temperature range. It displays all the features predicted by the theory, and shows the transition from case (*A*) to case (*B*). The minimum occurs for $\tau_c = 1/2\pi\nu_0$.



NUCLEAR MAGNETIC RELAXATION TIME T_1 FOR PROTONS IN GLYCERINE

Similar considerations seem to hold for some solids, in which the molecules still have, to some extent, a rotational degree of freedom. This is the case in ice, which also shows a dielectric dispersion. The relaxation time in ice has been measured from −2° C. (0·8 sec.) to −40° C. (20 sec.) at 29 Mc./sec., and is proportional to the Debye time τ_c, obtained from electric dispersion data. It is of the same order of magnitude as in water, but for a different reason, as we are on the other side of the minimum. Although Debye's theory is only concerned with polar molecules, it is clear that τ_c can be defined in a similar way for non-polar liquids. Measurements on a series of hydrocarbons from petroleum ether to heavy mineral oil show a decrease of the relaxation time from 2 sec. to 0·005 sec. with increasing viscosity. The local field $H(t)$ can be greatly enhanced by addition of a paramagnetic substance, resulting in a corresponding decrease in relaxation time. Data have been obtained for solutions containing Fe^{+++}, Cu^{++}, Er^{+++} in concentrations from 0·0002 to 0·5 mol. The relaxation time is inversely proportional to the concentration and, roughly, to the square of the magnetic moment of the ion. For F^{19} and Li^7 resonances in liquids results have been found similar to those for protons. Furthermore, the deuteron resonance has been observed at 4·8 mc. in a water sample containing 50 per cent deuterium. The relaxation time for D in this sample is 0·1 sec. Although the deuteron has a much smaller magnetic moment than the proton, this time is twenty times shorter than that for protons in the same sample, and must be ascribed almost entirely to the action of the quadrupole moment. One can repeat the above calculations for the electric quadrupole transitions by considering the 'local field spectrum' of the tensor grad·**E**. With the known value of the quadrupole moment, one obtains the experimental value of the relaxation time for a reasonable value of grad E in the polar liquid.

---

* Society of Fellows.

Finally, we must consider the spin-spin relaxation time and the closely related problem of the line width. In the limiting case of a solid in which the motion of molecules is very small, the line width can be calculated on the basis that the nuclei are at rest[8], and spin-spin relaxation is produced by the fact that neighbouring nuclei precessing with the Larmor frequency can exchange their energy. On the other hand, in a liquid like water, this exchange will be much smaller, since the rapid Brownian motion smears out the spectrum and averages out the local field. We conclude that in liquids ($\tau_c \ll 1/\nu_0$), T_1 and T_2 are proportional and of the same order of magnitude. But while T_1 passes through a minimum at $\tau_c = 1/2\pi\nu_0$, T_2 continues to decrease. The line width is a monotonic function of viscosity, at first linear, and asymptotically reaching a limiting value in the solid. Confirming this view, we find experimentally that the resonance line in water, glycerin, and other liquids at room temperature is extremely narrow. At 4·8 Mc./sec., an upper limit of 0·015 gauss has been established. The theoretical value according to the above considerations would be 0·007 gauss for glycerin and about 10^{-4} gauss for water. The broadening of the line in glycerin, mineral oil and ice, which can be observed at sufficiently low temperatures, is such that the line width is initially proportional to τ_c. In glycerin at $-30°$ C. the width is 1·5 gauss, in ice at $-5°$ C., 5 gauss, at $-30°$ C., 15 gauss. The line width in solutions of ferric nitrate is proportional to the concentration of the paramagnetic ion, and is 0·6 gauss in a 0·5 mol. solution with a relaxation time $T_1 = 3 \times 10^{-4}$ sec.

A detailed account of this investigation will be sent to the *Physical Review* and will appear in a thesis to be submitted by one of us (N. B.) at the University of Leyden.

STATE LABORATORY FOR EXPERIMENTAL BIOLOGY AND MEDICINE, NOVI SAD, YUGOSLAVIA

By Dr. PETAR N. MARTINOVITCH

Director

WHILE fighting was still going on in the Pannonian plains north-west of Beograd in 1944, a small group of young medical men and medical students (most of them in uniform) was busy collecting material left behind by the Germans, destined to become the nucleus of the present Laboratory for Experimental Biology and Medicine at Novi Sad, Yugoslavia. In due course they called on me to tell me that they wanted a laboratory for biomedical research. A site for the laboratory was yet to be found. Eventually, a deserted villa on the outskirts of the town was selected; but it was in an appalling condition, and many months of work were necessary to make it suitable for our purpose.

The United Nations Relief and Rehabilitation Administration sent a large amount of laboratory material to Yugoslavia; but it had to be shared by many laboratories and much of it was assigned to field work. Some valuable items, however, were allotted to our institute. Finally, due credit should be given to the progressive citizens of Novi Sad, who spared no effort to help the new laboratory. To-day the Laboratory is a State institution, and the authorities are giving ample credits for its support.

The available space in the Laboratory consists of four large rooms and six smaller ones. One room has been fitted for tissue culture work, and in the cellar there are a workshop, a washing room and a room where experimental animals can be kept. The building stands in a small park, and at the back is a garden with an enclosed space for poultry. The Laboratory is equipped with essential apparatus, instruments and a fair amount of glassware and necessary chemicals; all the equipment of my tissue-culture laboratory at Beograd was transferred to Novi Sad. The Laboratory owns eight hectares of arable land, where the animals are kept and the animal food grown.

Although the official status of the Laboratory was established in May 1946, experimental work did not begin until several months later.

The new Laboratory is being organised on a modest scale along the lines of the Strangeways Research Laboratory at Cambridge. No separate departments are planned and no programme of 'division of labour' on the research level will be attempted. Each laboratory unit will be developed around the man and the field in which he is most interested. Collaboration will be encouraged whenever necessary. No attempt will be made to encourage the Laboratory to grow beyond a certain definite size.

The Laboratory has four objectives, as follows: to bring under the same roof workers engaged in various fields of experimental biology and medical research; to establish the closest possible contacts with laboratories in other lands engaged in the same kind of work; to give an opportunity to promising young people interested in biomedical research to obtain elementary instruction in research methods, in order that they may be sent abroad sufficiently trained for advanced work; to 'popularize' biological science by publishing books and articles on recent advances made in this field of research.

At present there are only two of us working in the Laboratory, a young doctor of medicine and myself. We are expecting a third, a bacteriologist, to come from the United States, where he has been sent by the Rockefeller Foundation for special training. There are also several young men, now university students, whom the Laboratory hopes eventually to appoint to its staff. The problems at present being studied deal with the morphogenesis of the mammalian gonad, primarily of the germ cells, and with the gonadotrophic function of the pituitary gland.

The long years of war and occupation were a heavy blow to science in Yugoslavia. All research work was brought to a standstill. Completely shut off from the rest of the world, lacking even the most essential equipment for carrying on research, the small number of Yugoslav biologists, even if left alone by the enemy authorities (some were killed or imprisoned), were obliged to struggle for the bare necessities of life for themselves and their families. Since the War has ended, great efforts have been made to pick up the broken threads. But even now there are many obstacles. There is a shortage of almost every article essential to a research laboratory, great difficulties are encountered in replenishing depleted stocks, and reserve parts of precision apparatus are hard to get. Trained laboratory technicians are few, and so are electricians and mechanics acquainted with laboratory apparatus. We are also in dire need of technical books, journals and reprints of scientific papers. We would welcome reprints covering every field of biology and medicine, and the Laboratory at Novi Sad will be glad to forward them where they are most needed.

THE CHEMICAL SOCIETY'S CENTENARY EXHIBITION

THE exhibition at the Science Museum, arranged as part of the centenary celebrations of the Chemical Society, was a memorable one. For the first time, through the co-operation of the director of the Museum, Dr. H. Shaw, a comprehensive display of exhibits illustrating the progress of chemistry in Britain over the past hundred years was housed under one roof.

The exhibition, organised on behalf of the Chemical Society and the XIth International Congress of Pure and Applied Chemistry, by a committee under the chairmanship of Sir Robert Robertson, was divided into two parts, illustrating the history and the everyday uses of chemistry. The historical side was arranged under ten headings, each dealing with a section of the subject. Each section has been in the care of a panel of experts responsible for the selection of the exhibits, and for the corresponding chapter of the handbook to the exhibition. This handbook, "Chemical Progress" (London: H.M. Stationery Office. 1*s*. 6*d*. net), is a brief yet comprehensive survey of the British contribution to the science, which future students of chemistry may consult as a historical guide. The chairmen of the panels were Dr. A. E. Alexander, Dr. G. M. Bennett, Prof. J. D. Bernal, Prof. H. V. A. Briscoe, Dr. E. M. Crowther, Prof. C. W. Davies, Prof. D. H. Hey, Prof. C. N. Hinshelwood, Prof. E. K. Rideal, Prof. N. V. Sidgwick and Prof. M. W. Travers. The reports have been edited by Dr. F. Sherwood Taylor, curator of the Museum of the History of Science, Oxford.

A modern section dealing in a popular manner with "Chemistry in Everyday Life" was prepared by the Department of Scientific and Industrial Research, with the co-operation of the Agricultural Research Council, several research associations, and a number of industrial firms. The Central Office of Information prepared the layout of this part of the exhibition, which surveyed such fields as agriculture and food, health, homes and building, fuels, oil, transport and engineering. A popular account of this side was written by Dr. J. P. Lawrie, and this forms the second section of the handbook.

The exhibition was opened on July 14 by the president of the Chemical Society, Prof. C. N. Hinshelwood. The Minister of Education, Mr. George Tomlinson, was in the chair and welcomed the visitors. Prof. Hinshelwood in his opening speech said that the real adventures of science took place in the minds of men, and that much of the exhibition's interest would rely on the association of the objects to be seen with the men who used them.

It is impossible to do justice in the space of a short article to the many exhibits. In each branch of the subject the development was traced from the early pioneers. It was Faraday whose genius laid the foundations of so much of modern chemistry. His work on the alloys of steel was illustrated, as was that on the liquefaction of gases, the forerunner of all later researches in this field. His discovery of benzene was the start of modern organic chemistry, which was illustrated in all its aspects. His work on electrolysis has produced the modern science of electrochemistry, and the use of platinum as a catalyst. The visitor could also see, side by side with their more modern counterparts and developments, his samples of optical glass and colloidal gold.

Graham, too, the first president of the Chemical Society, was a pioneer whose experiments with simple apparatus led to the enunciation of the laws of diffusion in gases and liquids, and to the foundation of modern colloid science. The study of chemical reactions has increased our knowledge of molecular properties and brought about such material advances as photography and plastics. The early theories of valency and atomic structure put forward by Newlands and Crookes were demonstrated. These pointed the way for Mendeléeff, and also for Moseley, whose apparatus and ferrocyanide crystal were exhibited. In the range of inorganic chemistry the fundamental work of Dalton was illustrated by his diagrams of molecular structure. Near this were shown such diverse subjects as glass, precious metals, fluorine chemistry and fluorescent lighting, all items in which British chemists have played a decisive part.

The study of crystallography was represented by a large number of structural models and apparatus illustrating the development of theory and technique in this subject.

The important subject of agricultural chemistry, in which the early work of Lawes and Gilbert at Rothamsted pointed the way to modern scientific methods of increasing the fertility of the soil, was also given prominence.

It is, however, the organic chemist whose work offers the biggest variety of subjects. Each was illustrated by charts and specimens to show the structure, historical synthesis and applications of the substance. Individual exhibits showed early work in carbohydrates at St. Andrews and at Birmingham.

The development of synthetic dyestuffs and fibres was well represented, and space was given, to name a few examples, to synthetic drugs and chemotherapeutic substances including penicillin, and to British work on the vitamins.

The historical part of the exhibition was concluded by a small exhibit of British developments in analytical chemistry.

Space forbids a description of the attractive section on "Chemistry in Everyday Life", which explained in simple terms, by means of a series of illuminated screens and diagrams, the operations and processes by which the raw materials of the laboratory are turned into finished products.

It must be regretted that a historical exhibition on this scale cannot take a permanent place in the national collections, and it is to be hoped that when the Science Museum eventually obtains its long-needed extensions, an enlarged collection, on the lines of the exhibition which has just closed, may be reassembled.

CLIMATIC FLUCTUATIONS AND VEGETATION GROWTH IN NORTHERN FINLAND DURING 1890–1939

FIG. 1 shows the annual variations in the growth in diameter of pine (*Pinus silvestris* L.) near the timber line in the extreme north of Finland, at about lat. 69° 30′–70° N. The diagram is based on two series of figures[1]: (*a*) represents the weighted average of 148 increment cores collected in July 1939 and 1940; (*b*) represents the average of 58 increment cores collected in July 1945.

The diagram shows the great variation from year to year in the production of organic matter, in this case cellulose. We observe, moreover, an obvious 'low' period of growth during 1901–16, and the gradually increasing growth during the 1920's.

The timber-line forest is very susceptible to the smallest changes in climate (cf. the general statements by Griggs[2] and by Hustich[3]). Thus Fig. 1 may perhaps illustrate to some extent the general influence on growth in the northern part of the Eurasian coniferous zone of the most recent climatic changes. The names on the diagram are those of scientific workers who have expressed an opinion about the regression or progression of the timber-line. The signs − or + indicate that the author mentioned believed it to be receding or advancing respectively. Their opinions are reasonably well explained when considered in connexion with this cyclical growth curve. We can easily understand, for example, why Renvall[4], who worked in the 'low' period, demanded rigorous protection of the timber-line forest because of the "regression of the timber line"; and just as readily we understand why Eide[5], who worked in the 'good' period, was of quite another opinion. I think that the work of Russian scientific investigators on this subject during the same period would give a similar result. The 'low' period is also evident from the occurrence of seed years; there was no important seed year during the 'low' period, shown in Fig. 1, in the northernmost pine forests of Finland.

The same cyclical variation in the production of organic matter also appears in the crop variations of rye, barley, oats and potatoes in northern Finland. The positive trend or 'progression' in the period 1890–1939 is still more pronounced. The positive influence of the climatic improvement of the 1920's was, so far as cereals are concerned, over-accentuated by the improvement in cultivation methods in Finland in recent decades, and by the introduction of better varieties of the various cereals.

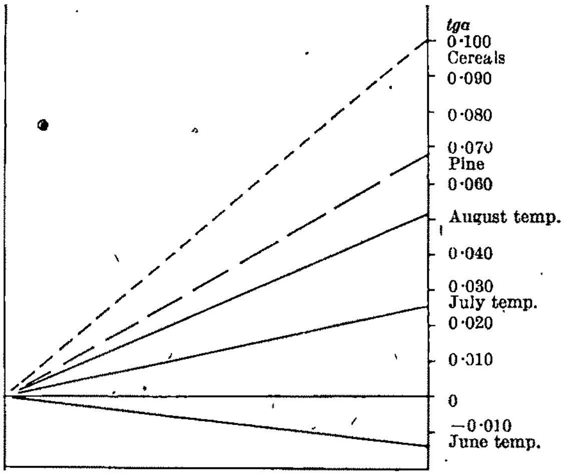

Fig. 2. THE *tgα*-COEFFICIENTS OF TEMPERATURE, CROP AND GROWTH (PINE) SERIES 1890–1939 ON AN EXAGGERATED SCALE. THE TERM 'CEREALS' IS THE AVERAGE OF THE CROP SERIES IN THE TABLE

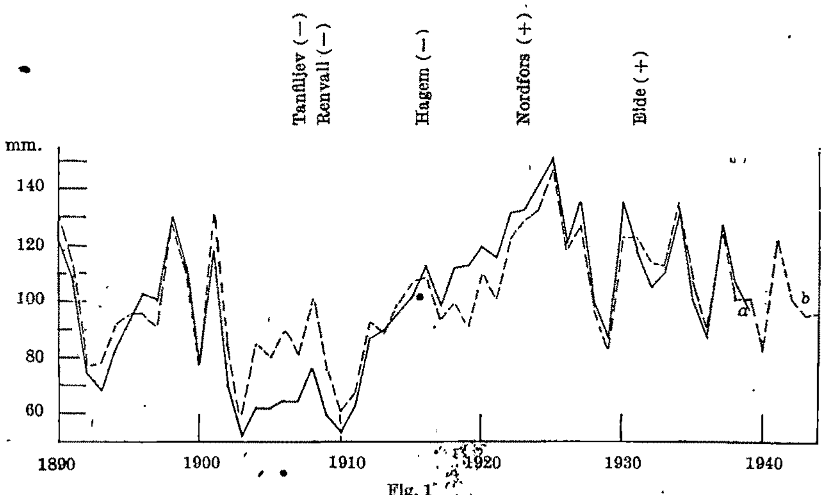

Fig. 1

In the accompanying table some information is given on the trend (the *tgα* coefficient of the series during 1890–1939) of some temperature indicators, and also of some crop-yield series and growth-series of pine (curve *a* in Fig. 1). The influence of precipitation on growth in the far north is, as is known, of minor significance.

We find that the June temperature shows a slight negative trend, but the July temperature, and especially the August temperature, increased appreciably during the period 1890–1939 (see Fig. 2). Moreover, the positive trend in the growth in diameter of pine is slightly higher than that of any climatic indicator, thus showing that even a fairly small increase in temperature may result in much accentuated growth[1]. The improvement in the cereal crop has been commented on above. Thus the table and Fig. 2 together give an idea of the general climatic influence on growth phenomena and on the production of organic matter during the period 1890–1939. (There are great annual variations not only in the quantity but also in the quality of the organic matter produced; for example, the annual variation in the amount of potatoes is not correlated with the variation in the percentage of starch of the crop.)

REGRESSION (*tgα*), STANDARD DEVIATION (σ) AND VARIATION COEFFICIENT (% σ/M) IN TEMPERATURE, CROP AND PINE GROWTH-SERIES IN NORTHERN FINLAND

Series (1890–1939)	*M*	*tgα*	σ	% σ/M
June temperature at 65° N.	12·8° C.	−0·014	1·7	13·7
July temperature ,,	16·5° C.	0·025	1·9	11·5
August temperature ,,	13·9° C.	0·051	1·7	8·9
Rye, relative crop values	7·2	0·106	2·2	30·3
Barley ,, ,, ,,	5·3	0·115	1·6	31·4
Oats ,, ,, ,,	5·1	0·076	1·6	30·2
Potatoes ,, ,, ,,	6·0	0·121	2·3	38·0
Pine growth (in 1/100 mm.)	99·8	0·068	2·6	25·7

In the table the variation coefficients (% σ/M) for the series used are also given. Note the high ratio of the annual variation, especially in the crop series, showing clearly the uncertainty of agriculture in northern Finland (north of lat. 65° N.).

The variation coefficient, or as I would prefer to call it, the 'climatic hazard coefficient', decreases when moving south, being only about 11 per cent for the crops in southern Finland.

In forestry the same phenomenon, namely, increased variability in growth towards the north, can be noticed. The growth measurements made during the second national forest survey of Finland during 1936–38 show that the 'climatic hazard coefficient' for pine is about 23 per cent in northern Finland and about 18 per cent in southern Finland, the corresponding figures for spruce being somewhat lower, namely, 20 per cent and 15 per cent, respectively. This increasing 'variation coefficient' or 'climatic hazard coefficient' from south to north which I have demonstrated corresponds fairly well with the idea that the 'improvement' in recent decades has been most evident in northern countries. It would be of interest to receive information from other parts of the coniferous zone concerning this subject.

I. HUSTICH

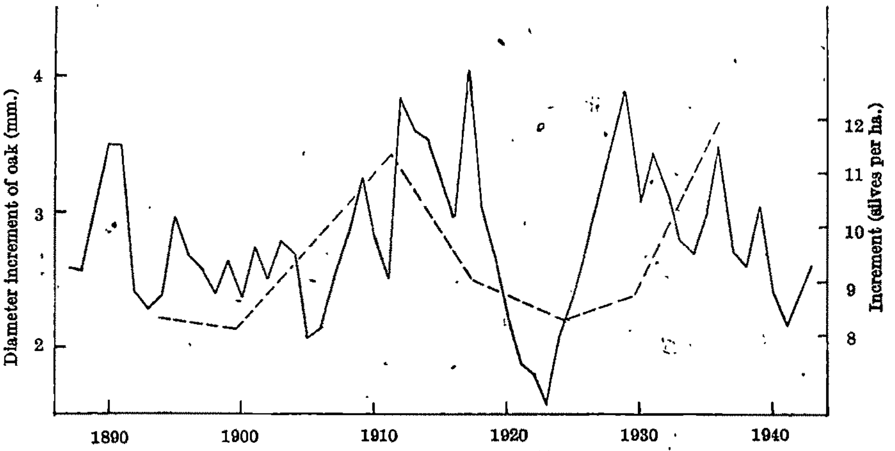
[3] Hustich, I., *Geograf. Ann.* (Stockholm, 1943).

[4] Renvall, A., *Acta Forestalia Fennica*, 1 (Helsinki, 1912).

[5] Eide, E., *Medd. Norske Skogsførs. vesen*, 3 (Oslo, 1932).

It seems probable that the fluctuations in plant growth in northern Scandinavia to which Dr. Hustich directs attention are examples of a general phenomenon which will prove to be traceable over the whole of the North Temperate region. Two further examples are shown in the accompanying figure. The first curve represents the mean diameter increment of eight old trees of oak (*Quercus sessiliflora* Sals.) growing in unenclosed woodland near Brook in the New Forest, Hampshire, England. Exactly the same trend is shown by rather younger oak (about two hundred years old) in adjacent enclosures, and by pedunculate oak (*Q. robur* L.) in other parts of the New Forest. The second curve represents the volume increment of mixed silver-fir–spruce forest in the Swiss Jura[1], in silves per hectare, between successive enumerations made at intervals of approximately five years. (A 'silve' is a volume of one cubic metre estimated from the diameter of the trunk and the known average diameter–volume relationship.)

Both these curves show unmistakably the tendency to rise from about 1890 until about 1930, but whereas, according to Hustich, the Finnish curves are unaffected by rainfall, the upward trend of the Swiss and English curves is interrupted by severe depressions associated with the dry periods culminating in 1921 and 1935. The fall in growth from 1930 onwards is shown both in Finland and in England, and it has continued throughout the wetter period which followed 1935, so that it may be associated with a fall in temperature—a possibility which is suggested by the temperature curves for Switzerland published by Favre; these curves show quite clearly the general rise in temperature from about 1890 up to 1930.



FULL LINE, MEAN DIAMETER INCREMENT OF OAK, NEW FOREST. BROKEN LINE, VOLUME INCREMENT OF SILVER-FIR-SPRUCE FOREST IN SWISS JURA

The rise in temperature over this period has apparently also been demonstrated in America[2], and it accords with much that is known concerning the behaviour of glaciers and ice-caps.

It seems clear that the investigation of the trends of growth shown by trees over long periods, as distinct from the attempts to interpret the peculiarities of individual rings, is a very promising field of work.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Saturday, October 4

Institution of Mechanical Engineers, Graduates' Section (at Storey's Gate, St. James's Park, London, S.W.1), at 3 p.m.—Discussion on "A Survey of Combustion Research as applied to the Internal Combustion Engine" (to be opened by Mr. N. P. W. Moore).

Monday, October 6

Society of Engineers (in the Apartments of the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. C. D. Mitchell: "Prefabricated Pre-Cast Concrete Structures, including Floating Craft".

Society of Chemical Industry (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Mr. J. W. Walker: "Synthetic Drugs in the Fight against Tropical Diseases".

Tuesday, October 7

Chadwick Public Lecture (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 2.30 p.m.—Brigadier A. E. Richmond: "Positive Health—its Attainment in the Soldier, and the Army's Contribution to it in the Civilian".*

Institution of Post Office Electrical Engineers, London Centre (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 5 p.m.—Mr. J. Neale and Mr. W. E. Adams: "Some Recent Developments in the Design of Short Wave Receiving Stations".

University College, London (in the Physiology Theatre, Gower Street, London, W.C.1), at 5.15 p.m.—Prof. J. Z. Young, F.R.S.: "The Structure of Peripheral Nerve and of Nerve Endings" (further lecture on October 14).*

Institute of Physics, Electronics Group (in the Rooms of the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Prof. D. R. Hartree, F.R.S.: "Electronic Calculating Machines".

Institution of Mechanical Engineers, Automobile Division (at Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—First Annual General Meeting of the Division; Mr. S. Markland and Mr. N. Tattersall: "High Speed C.I. Engines".

Wednesday, October 8

University College, London (in the Physiology Theatre, Gower Street, London, W.C.1), at 5 p.m.—Dr. M. H. Pirenne: "The Physiological Mechanisms of Vision" (further lectures on October 15, 22, 29, November 5 and 12).*

Institute of Petroleum (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. B. B. Morton: "Metallurgical Methods for Combating Corrosion and Abrasion in the Petroleum Industry".

Society of Chemical Industry, Microbiological and Nutrition Panels of the Food Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Discussion on "Microbiological Proteins; their Synthesis, Production and Feeding Value".

Thursday, October 9

Imperial Institute, Mineral Resources Department (in the Cinema Hall, Imperial Institute, South Kensington, London, S.W.7), at 3 p.m.—Mr. S. H. Shaw: "The Geology and Mineral Resources of Palestine" (Recent Progress in Geological Investigations and Mineral Developments in the Colonies, 8).*

Chemical Society (joint meeting with the University College of North Wales Chemical Society, in the Chemistry Lecture Room, University College of North Wales, Bangor), at 4 p.m.—Sir Ian Heilbron, F.R.S.: "D.D.T. and Gammexane in the Control of Insect-borne Diseases".

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. P. Good: Inaugural Address as President.

Royal Aeronautical Society (in the Lecture Hall of the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Mr. W. M. Widgery: "Pressurisation of Aircraft".

Friday, October 10

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

Chemical Society (joint meeting with the Southampton University College Chemical Society, in the Physics Department, University College, Southampton), at 5 p.m.—Prof. C. C. Price: "The Influence of Substituents on the Polarity of the Benzene Ring".

Saturday, October 11—Saturday, November 1

Royal Photographic Society (at 16 Prince's Gate, London, S.W.7).—Ninety-second Annual Exhibition. Part 2: Scientific, Nature, Record and Technical.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Mining, and a Lecturer in Electrical Engineering at the Cannock Chase Mining College—The Director of Education, Dept. F.E., County Education Offices, Stafford (October 11).

Junior Laboratory Technician (Grade C)—Dr. M. Reiss, Bristol Mental Hospital, Fishponds, Bristol (October 11).

Teacher in the Mathematics and Physics Department—The Principal, Municipal Technical College, Hopwood Lane, Halifax (October 11).

Assistant in Agriculture at the Essex Institute of Agriculture—The Chief Education Officer, County Offices, Chelmsford (October 13).

County Agricultural Advisers (7), Experimental Officers (2), Horticultural Advisers (2), a Horticultural Instructor, Instructresses (2) in Dairying and Poultry-Keeping, and an Apiarist, for posts in the County Extension Services of the College—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh (October 15).

Scientists (Grade III) for the National Coal Board: a Physical Chemist and Physicist in Greater London for laboratory research into dust problems in mines, Ref. No. F.794/47A, a Physicist for applied research in North Staffs coalfields on problems of firedamp and ventilation in mines, Ref. No. A. 339/47A, a Physicist for laboratory research on underground illumination, Ref. No. A.340/47A, and a Mechanical Engineer for laboratory research into development of dust control equipment, Ref. No. C.567/47A—The Ministry of Labour and National Service, Technical and Scientific Register, Room 669, York House, Kingsway, London, W.C.2, quoting appropriate Ref. No. (October 18).

Senior Assistant in Mechanical Engineering, a Responsible Lecturer in Production Engineering, a Lecturer in Electrical Engineering, a Lecturer in Science Subjects (with either Chemistry or Biology or Metallurgy as a main subject), a Lecturer in Mathematics, and a Lecturer in Building Subjects—The Principal, Luton Technical College, Park Square, Luton (October 20).

Lecturers in Mechanical or Electrical Engineering in the Cape Technical College, Cape Town—J. A. Ewing and Co. (Ldn.), Ltd., Finsbury Court, Finsbury Pavement, London, E.C.2 (October 20).

Research Assistantship in the Nuffield Department of Industrial Health—The Registrar, King's College, Newcastle-upon-Tyne (October 31).

Soil Conservation Officer by the Government of Ceylon for the Department of Agriculture—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.N.18513 (October 31).

Lecturer in the Mathematics Department—The Principal, Heriot-Watt College, Edinburgh (October 31).

Principal of the Paddington Technical Institute, Saltram Crescent, W.9—The Education Officer (T.1), County Hall, London, S.E.1 (November 1).

Assistant Lecturer in Mycology—The Registrar, The University, Manchester 13 (November 7).

Lecturer in Psychology at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (November 10).

Physicist or Physical Chemist (preferably with experience in electronics)—The Director, British Launderers' Research Association Laboratories, Hill View Gardens, London, N.W.4 (November 13).

Senior Lecturer in Psychology at the Victoria University College, Wellington, New Zealand—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (November 14).

Chair of Oriental Studies—The Registrar, University of Sydney, Sydney, N.S.W., Australia (November 30).

Assistant in Department of Chemical Pathology—The Chemical Pathologist, Westminster Hospital Medical School, 17 Horseferry Road, London, S.W.1.

Engineer in the Ionosphere Section of the Overseas and Engineering Information Department of the B.B.C., based in London—The Engineering Establishment Officer, Broadcasting House, London, W.1.

Junior Organic Chemists—The Secretary, British Rubber Producers' Research Association, 19 Fenchurch Street, London, E.C.3.

Laboratory Assistant to take charge of physics laboratory—The Bursar, Haileybury and Imperial Service College, Hertford.

Laboratory Assistant (Grade I) in the Department of Physiology—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1.

Senior Lecturer in Agriculture—The Principal, Harper Adams Agricultural College, Newport, Shropshire.

Biochemist (preferably with some experience of research) for work on the separation and properties of macro-molecules—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

Head of the Electrical Engineering Department—The Director of Education, The Polytechnic, 309 Regent Street, London, W.1.

USE OF THE LAND IN BRITAIN

THE interest in the first annual report of the Local Government Boundary Commission (London : H.M. Stationery Office. 4*d.* net), which covers the year 1946, lies less in the factual account of changes or proposals for change recorded than in the appraisal of local government opinion in Great Britain which the Commission has such a unique opportunity to present in the course of its inquiries. The task of the Commission is to make, so far as is practicable, all local government authorities, both individually and collectively, effective and convenient units. That in itself is an immense task, involving the review of the status and boundaries of 61 counties, 83 county boroughs and 1,356 county districts, and the Commission recognizes frankly that procedure is experimental and that the task can only be accomplished successfully with the active goodwill and co-operation of the local authorities themselves.

Nor is this all. The task is related not merely to that of post-war reconstruction and planning generally. It has implications for many of the measures already enacted or under consideration by the Government, such as the Town and Country Planning Bill, the areas of the regional hospital boards under the National Health Service Act, and the proposals for national parks and Nature reserves outlined in the Hobhouse Report, not to mention the location of industry, agriculture, forestry, and water and power supply.

The decisions thus far announced are mainly negative and incomplete, indicating the kind of proposal that is unlikely to be approved, but not the extent to which changes may ultimately proceed. It will be noted, however, that Plymouth's progressive housing policy has been thwarted, on the advice of the Minister of Town and Country Planning, by the refusal of space for the proper accommodation of half the overspill provided for in the Abercrombie plan. The Commission has here shirked the planning responsibilities which are inseparable from the proper discharge of its responsibilities ; but in general its broad review indicates that the Commission is cognizant of the issues involved in the various types of proposals for change.

Meanwhile, however, the Commission has noted the unanimity with which representatives of rural districts have based their objection to absorption into boroughs on the consequential loss of the parish councils or the parochial committees. On the other hand, the larger towns are frequently interesting themselves in the new conception of neighbourhood units and community centres, and most plans for the development of new estates on the periphery or for redevelopment of central areas provide for such units.

The Commission does well to suggest that these two ideas might be brought into contact. There is real danger that with the need for provision of some services by large and therefore somewhat remote authorities operating over wide areas, the ordinary citizen will lose interest and contact with the local government and the elected representatives of his own locality.

The Commission here touches on one of the greatest dangers in the regional system. It is vital in a democracy to preserve and to extend the means for the expression of local views and for maintaining local interest. The Hobhouse Committee equally recognizes this, insisting on the importance of national control and a national policy for Nature reserves, as did the Dower Report, and that central management and development must be planned from the start in adjustment with other essential interests in the land, such as agriculture, forestry, water supply, communications and building; but the importance of enlisting local knowledge and experience, and encouraging and maintaining local interest and co-operation, cannot be too much emphasized.

The most casual consideration of the relation of the areas of the proposed national parks and of the counties and county boroughs falling within the parks should be sufficient to demonstrate the value of such co-operation and interest; nevertheless, there have been repeated incidents in recent years in such matters as highway development, water supply or hydro-electric schemes or the location of industry which indicate how rash it would be to rely upon unguided local bodies to consider matters from a national or even a regional point of view. There is a most important task of education to be undertaken before democratic planning can become a reality. Political and Economic Planning has already given attention to this matter in a series of broadsheets issued earlier this year. "Active Democracy—A Local Election" (No. 261), "Clubs, Societies and Democracy" (No. 263) and "Public Relations and the Town Hall" (No. 265) all examined different facets of the problem. But a later broadsheet, "The Plan and the Public", which has recently appeared, goes to the heart of the matter; it is of vital interest at the moment not only in relation to local government but also to the issues involved in the present economic crisis.

This broadsheet puts in their proper perspective some of the problems which arise in carrying through the experiment in democratic planning to which Great Britain is committed, and asks some of the awkward questions about our social institutions and attitudes which must be answered if the active participation of the citizen in the planning process is to become a reality. It is a most valuable contribution to the assessment of the task of the new Economic Planning Board, and of the decisions to be taken by the Government as well as of the limitations of Government action. It emphasizes the responsibilities which both the Government and the Opposition must accept, quite apart from that of maintaining an atmosphere of free discussion and criticism. *Planning* does well to direct attention to the large measure of common ground in the economic plan, to the plain fact that an Opposition on coming into power would have to start where the old plan left off, and that the essential co-operation cannot be expected if the Government shows itself reluctant to accept it or if its representatives go out of their way to use phrases calculated to exacerbate hostility. These are timely reminders, no less than the further one that democracy implies the right of the people to discharge planners whose plan fails to operate continuously and genuinely to meet the requirements of the consumer. Leadership, persuasion and effective forethought are essential in democratic planning; without them come threat and compulsion, and there has been evidence at times that we are verging uncomfortably near such a regime.

The broadsheet limits itself to the consideration of the first two of the three elements—consultation, communication and execution—involved in democratic planning. In regard to the first, it directs attention to factors which have weakened the claim of the House of Commons to be the exclusive source of information about public opinion, and reviews the development of consultative machinery, the need for which was stressed in the new planning proposals of the Government announced in March 1947. One of the purposes of the development councils to be established under the Industrial Organisation Act is to facilitate consultation; but as the broadsheet observes it is doubtful whether any better or more representative body than the House of Commons can really be found so far as consumers are concerned, and the logical step would be the devolution of more responsibility on local authorities as custodians of consumers' rights. The need for other *ad hoc* bodies implies a reflexion on the representative character of elected local councils.

The main point brought out by the broadsheet on this question of consultation is that, to be effective, consultation needs to be continuous. Spasmodic reference of a particular Bill or a special problem to an interested group or an advisory body is not enough. Furthermore, *Planning* puts some all-important questions about the nature of such organisations. Are their leaders truly representative of the interests and of the men and women in whose name they speak? How far are they capable of leading as well as listening, of throwing up economic statesmen rather than mere spokesmen of sectional interests? And do they provide effective means for the speedy transmission of views both from centre to periphery and from periphery to centre?

There are wider constitutional issues implicit here, and the fuel crisis early in the present year revealed how serious they may be. It was disturbing to find that the Government attempted, for example, to justify the suspension of periodicals not so much as in the national interest as in conformity with an agreement made with an association representing some of the proprietors of periodicals. Ultimate responsibility must clearly rest with Ministers answerable to Parliament, but equally the Government must use consultative machinery as a real aid to making decisions and softening their impact when made, and not as a pretext for delay and postponement of decisions which it is too hard-pressed or too timorous to make for itself.

Nothing could illustrate this better than the present position of the Service land requirements in relation to the proposals for national parks and Nature reserves, as the continuous stream of criticism of the Interdepartmental Committee shows. A written statement from the Minister of Town and Country Planning on July 29 showed that only four of the twelve areas proposed for national parks are at present free from Service demands. Of the 392,960 acres of North York moors 27,500 acres are held for training and other purposes; 26,000 acres out of 146,560 of the Pembrokeshire coast, 47,500 out of 327,168 of the Brecon Beacons and Black Mountains, 41,600 out of 250,880 of Dartmoor; while since the statement was made a fresh threat has become apparent to the Lake District, where in addition to the 700 acres at present held, a further 10,000 acres in the Coniston area is requested by the War Office. Service departments should not be exempted from the control exercised in the public interest.

These figures take no account of the threats to the numerous areas proposed as Nature reserves, and the whole trend of the reply of the Minister to the question regarding the public inquiry into the proposed Dartmoor training areas indicates the failure of the Government to appreciate the importance of this question of consultation, or that evasion of the issue may endanger the success of the whole experiment of democratic planning. It might even be argued that one factor in our present critical economic position has been lack of effective consultation; and it is certain that the nation as a whole is at present nowhere near possessing either a sufficiently wide and general understanding of social and economic affairs, or a sufficiently disinterested and public-spirited attitude towards them to enable this or any other Government to carry through the immensely difficult task of democratic planning with which we are faced. Nothing less than a sustained and intensive attempt, with a carefully thought-out strategy, to raise the level of public understanding and to change the attitude of ordinary people towards their social and economic responsibilities, will ensure the support on which the Government's plans for meeting the crisis depend for success.

In such a campaign, as *Planning* points out, not merely the Government with its specific publicity organs but also nearly every organised group and institution in Britain will have its part to play. Scientific institutions or associations have their own special contribution, for which they may have to go through a period of trial, adaptation and transformation to enable them to take the new part in public life which an era of democratic planning demands of them.

Looked at broadly, it is a part of the old question of relating knowledge to action, securing the 'climate of opinion' which will permit policy to be framed and decisions taken in accordance with the facts which scientific inquiry has already brought to light. As Sir Oliver Franks has put it, the Government's plans must be made the plans of the nation, so that they are animated by the constructive endeavour of the managements and workers who carry them out.

THE POETS' VIEW OF NEWTON

Newton demands the Muse

Newton's *Opticks* and the Eighteenth Century Poets. By Marjorie Hope Nicolson. (History of Ideas Series.) Pp. xi+178. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1946.) 11*s*. 6*d*. net.

IN 1728 Henry Pemberton published "A View of Sir Isaac Newton's Philosophy", which gave a popular account of the contents of the "Principia" and of the "Opticks". To it the author prefaced "a copy of verses on Sir Isaac Newton, which I have just received from a young Gentleman, whom I am proud to reckon among the number of my dearest friends". The young gentleman was Richard Glover, best known to students of eighteenth century literature as the writer of "Leonidas" and one of the many reputed authors of the "Letters of Junius". In the invocatory lines he exclaims:

> "Newton demands the Muse; his sacred hand
> Shall guide her infant steps."

and it is from this passage that the book now before us takes its title.

Miss Marjorie Nicolson, who is well known to the curious for her studies of the effect of scientific discovery on the literary imagination in times past, sets out to show the great influence which Newton's work, and specifically the publication of the "Opticks", had on the poets of the eighteenth century. In this connexion there are certain names that occur at once to anyone familiar with the period, in particular James Thomson, whose "Poem Sacred to the Memory of Sir Isaac Newton" shows a just and gracefully expressed comprehension of Newton's achievements and whose "Seasons", as Miss Nicolson points out with many examples, also shows a strong Newtonian influence. Thomas Young, of the "Night Thoughts", which was a 'best seller' in its time, and Mark Akenside may, perhaps, also be considered as obvious candidates in this connexion, and they are abundantly cited. These three, however, form but a small part of the company that the author invokes.

Richard Blackmore, best known for his "Prince Arthur", wrote a long poem, "Creation", in which he dealt not only with the "Principia" but also with the "Opticks", showing some misunderstanding of wave propagation, in which Miss Nicolson follows him: John Reynolds, quite neglected to-day —and rightly, for his "View of Death", which had something to say of Newton's discoveries, was, as our author freely admits, insufferably tedious; Moses Brown, who wrote an "Essay on the Universe"; and Henry Brooke, whose "Universal Beauty", judging by the specimens quoted, gave a not very accurate account of certain optical phenomena, were poets who concerned themselves directly with expressing Newton's discoveries, as did, in better poetry and sense, Thomson and Glover. Christopher Smart, Mallett in "The Excursion" and others were content with general rhapsodical descriptions of light and colour. It might be thought at first that this was not all due to Newton's influence, but if one considers the number of direct references to the great man in some of the poets cited, and more particularly if one searches, as I have done, for similar passages in Spenser and other pre-Newtonian poets, one is brought to agree that Miss Nicolson has made out a very good case for her theme that Newton was responsible for the great attention which the early eighteenth century poets gave to light and colour, even when they did not quote him directly.

There are occasional exaggerations, as when Shelley's famous

> "Life, like a dome of many-coloured glass,
> Stains the white radiance of eternity"

is attributed to Newton's prism, for why should the absorption colours of stained glass be termed prismatic? Pope, it is true, refers directly to "False eloquence like the prismatic glass", but it requires some effort to trace a Newtonian influence, as does our author, in the description of the garments and wings of the sylphids, just because of the glitter and colour. In referring to this passage and on other occasions Miss Nicolson speaks of light being refracted into colour, as if all colours, including in particular the scattering colours of cloud and mist, were refraction colours, a misunderstanding which possibly some of the poets have shared, but which the critic might well avoid.

In the last chapters of the book, which deal with the metaphysical implications of the "Opticks", Miss Nicolson rather deserts her main theme to consider the effect of Newton's cosmogony on his more materialistic disciples and the reaction of the school of Pope against those who thought that the road to all truth lay through experimental science. The book concludes with a very interesting consideration of William Blake's violent attacks on his antipathies, Bacon, Locke and Newton, whom he grouped together as doubters and unbelievers. "God is not a mathematical diagram" expresses his reaction in one sentence.

It is strange to find that one so well read in the eighteenth century as Miss Nicolson should suppose that when Newton wrote "I intend to be no further solicitous about matters of Philosophy" he meant by philosophy what we mean nowadays. He had in mind, of course, what we now call science, as is quite clear from, for example, the celebrated "Philosophy is such an impertinently litigous lady" letter, and from the very title of Pemberton's book, quoted at the beginning of this review. Miss Nicolson, on what ground I know not, says that "he would have preferred the proud title 'theologian' to that of either 'philosopher' or 'scientist'"—he could scarcely have contemplated the latter title as the word was not, so far as I know, used until 1840 or so. What she means by saying that ever since his death Newton has been considered a metaphysician I cannot conjecture. Nobody ever stated more clearly than Newton what he was trying to do in the "Opticks", the book with which she is particularly concerned—"My design in this Book is not to explain the Properties of Light by Hypotheses, but to propose and prove them by Reason and Experiments". There is not much metaphysics there.

The book, which throws a novel light on an interesting aspect of the eighteenth century temperament and tradition, is likely to appeal to a wide range of scholars, scientific, literary and philosophical. It is all the more a pity that the references, which are copious, are given in so unsystematic a fashion. Whatever else is added, the first edition should always be quoted, if only to give the date of the original appearance, but this is seldom done, nor does there seem to be any rule as to which edition is selected, the earliest or the latest. Sometimes for the same poet, in different places, the reader is referred to a first edition, to Chalmers' collection, to Johnson's collection, and to an unspecified edition. In the case of long poems there is often no indication as to where a passage quoted is to be found. Strangest of all is a reference for Voltaire's poem, addressed to Madame La Marquise du Chatelet, namely, to the "Oeuvres Complets de Voltaire" of 1785. This poem was prefaced to Voltaire's "Elémens de la Philosophie de Neuton" which appeared in 1738 and went through several editions, contributing largely to the popularization of Newton's work. An English translation, by Hanna, which includes the poem in question, appeared in the same year as the French original. It would scarcely be worth while mentioning these matters if Miss Nicolson's wide reading and scholarship did not make them surprising. In any case, they do not diminish the warmth of our welcome to this unusual and entertaining study of Newton's influence. E. N. da C. Andrade

MECHANICS OF ROAD-MAKING MATERIALS

Soils, Concrete and Bituminous Materials

A Record of a Course Dealing with Airfield Construction given at the Road Research Laboratory, Department of Scientific and Industrial Research, July–August 1943. Pp. 288. (London: H.M. Stationery Office, 1946.) 10*s.* net.

MORE than twenty experts in soil mechanics, concrete construction and road engineering have contributed to this valuable record of lectures, dealing with the problem of designing and constructing runways under the great variety of conditions encountered during the War in all parts of the world. A large proportion of the lectures outline various theories of soil mechanics in regard to the capacity of the ground to support load, in order to show how laboratory and field tests can be used to predict the behaviour of the ground under load. Of these, load-settlement curves obtained for small test areas of ground, suitably adjusted for full-scale loading and moisture conditions, would appear to be the soundest method of obtaining safe values of the modulus of soil reaction which, together with the tensile and elasticity characteristics of the concrete, determines the thickness of the latter in the form of a road slab, required to support a given point load. Methods of improving the condition of the sub-grade by drainage, soil stabilization and consolidation are described in detail. A full account is given of the procedure of grading local aggregates and controlling the ratio of water to cement in order to produce the strongest concrete. The use of special devices such as steel mesh tracks on sandy surfaces and blasting in swamps are described, and a whole section is devoted to tar and bituminous surfacing and soil stabilization.

One chart is supplied giving some indication of the values of the sub-grade modulus for various kinds of soil. This is gratifying, as values of this factor, which covers the principal soil mechanics data required by foundation and road engineers, have so far only occasionally been published. Records of the settlement of oil tanks which have flexible bases and cover a large area of ground are probably the best source from which to obtain this valuable information.

No method of designing highly reinforced and flexible concrete road slabs is given. Assuming soil reactions to vary in accordance with a straight-line law greatly facilitates calculations of this type and is justified in view of the vagueness of sub-grade modulus values. It is, then, simple to take into account, and use to the greatest advantage, slab flexibility in reducing bending stresses.

The publication of these lectures provides the road engineer with most of the practical details he requires in regard to recent developments in road and runway construction, both in the United States and Great Britain, and also a theoretical background in regard to soil mechanics, enabling him to relate the results of laboratory tests to the strength of the sub-grade and road slab in supporting wheel loads. Dr. Glanville, his staff and the various lecturers who contributed, are to be highly congratulated on a work which will be of great value to road engineers in all parts of the world.

STAR POSITIONS

Apparent Places of Fundamental Stars, 1947

Containing the 1535 Stars in the Third Fundamental Catalogue (FK3) of the Berliner Jahrbuch. (Published by Order of the Lords Commissioners of the Admiralty.) Pp. xxxii + 538. (London: H.M. Stationery Office, 1946.) 42*s.* net.

UNTIL 1940 each of the principal almanacs in various countries published the apparent places of a different selection of stars, the places of which were not even always referred to the same fundamental system. In addition, the number of stars for which the apparent places were given in any one almanac was insufficient. As a result of discussions at the International Astronomical Union in 1932, 1935 and 1938, it was decided that the Third Fundamental Catalogue of the "Berliner Jahrbuch" should be used as the fundamental catalogue for apparent places of stars in all ephemerides. It was further recommended that the apparent places of all the stars in that Catalogue should be published in a single volume, the calculations being carried out by France, Germany, Spain and the United States, Great Britain undertaking the printing. The first volume appeared in 1941, and subsequent issues have retained practically the same format except for temporary omissions owing to war-time difficulties. The late appearance of the 1947 volume, which should have been published in May 1946, is exceptional.

The introduction is printed in four languages—English, French, German and Spanish—and provides full explanations with examples of the use of the different auxiliary tables, together with a list of the corrections applied for parallax and orbital motion.

The first section, comprising 34 pages, gives the mean places of all the stars (1947·0) with their annual variations, proper motions and mean errors. The next and largest section contains the apparent places, at upper transit at Greenwich for every ten days, of 1,483 stars the declinations of which lie between ± 81°. First differences are given for each co-ordinate to facilitate interpolation, and at the foot of each page is subsidiary information on mean place, mean error, secant and tangent of mean declination, etc. Section 3 gives the apparent places, for every upper transit over the Greenwich meridian, of fifty-two stars lying within 9° of the two celestial poles. These include the effect of short-period terms of nutation, and subsidiary information is provided. Section 4 contains short-period terms of nutation in longitude and latitude, mean and apparent sidereal time, at 0^h, tables for converting mean solar to sidereal time and vice versa, and also for converting hours, minutes and seconds to decimals of a day, corrections to a linear interpolate for the effect of second differences, and corrections for diurnal aberration. The last section gives an index to the apparent places of stars, and many of them are given more than one name to facilitate the search for their positions.

This publication will naturally find a place in every observatory engaged in fundamental observations. It will also prove very valuable to institutions engaged on accurate surveys, for which there is not sufficient selection of stars in the almanacs. M. DAVIDSON

SCIENCE IN PROGRESS

Science in Progress

By Frank B. Jewett, James B. Macelwane, Donald W. Kerst, Hugh S. Taylor, L. Michaelis, Michael Heidelberger, G. W. Beadle, Peyton Rous, E. C. Stakman, Carl Caskey Speidel, Herbert M. Evans. Edited by George A. Baitsell. Fifth Series. Pp xv + 353. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1947.) 5 dollars.

THE fifth series of "Science in Progress" contains reports by ten leading American men of science in their respective fields and an introduction by Frank B. Jewett, president of the National Academy of Sciences, on "The Future of Scientific Research in the Post-war World". He has estimated the effect of the War upon "fundamental and applied science and scientific manpower". His plea is for a reconsideration of the scope and importance of fundamental research. A mere beating of swords into ploughshares is only a part of the problem. He is particularly impressed by the increasing use of team-work and mathematical machines in scientific research. For the most part all the chapters in the specialized fields can be followed by any reader with a grammar school scientific training.

Some of the chapters are noteworthy as models of thorough, scholarly yet simple treatment. Of these, D. W. Kerst's account of the development of the betatron, H. S. Taylor's history of contact catalysis between the two World Wars, G. W. Beadle's chapter on genes and the chemistry of the organism, and Peyton Rous's essay on the cancer problem are particularly outstanding for their directness and clarity. Rather more technical in style, but masterly and up to date, are the chapters by J. B. Macelwane on the interior of the earth and seismology, by L. Michaelis on oxidation and respiration, Michael Heidelberger on serological complement, E. C. Stakman on the difficulties of dealing with plant diseases, and Herbert Evans on hormones. The last, containing such sentences as "hepatic gluconeogenesis which adrenal cortical hormones characteristically produce", may make hard going for the layman in physiology. By contrast, the description given by C. C. Speidel of the cinephotomicrography of living cells in action makes easy reading.

It is to be hoped that Yale University Press will continue to issue such annual accounts of recent work in science. The general production of the book may make British readers rather envious of the qualities still maintained in the United States.

W. L. SUMNER

EDUCATION OF THE MAN OF SCIENCE

By Sir JOHN LENNARD-JONES, K.B.E., F.R.S.

LARGELY as a result of the War, there is now wider recognition of the possibilities of science and the powers of the trained man of science. This is reflected in the growing interest of contemporary literature in scientific affairs and in the frequency with which the opinion of scientific workers is sought on major matters of State. This improved status of science can only be maintained if men of science adopt a greater sense of responsibility; for the searchlight which is focused on them will necessarily expose their limitations as well as their strength. It is fitting, therefore, that at this time men of science should subject themselves to a searching inquiry of their training and qualifications. No place could be more appropriate as a forum for such a discussion than a meeting of the British Association, where all branches of science are represented and where so many sections of the scientific community assemble. At the recent meeting at Dundee a general discussion, supported by all the sections, took place on "The Education of the Man of Science" and attracted a large and representative audience.

The importance which the British Association attached to the discussion was indicated by the presence of the president, Sir Henry Dale, in the chair. The principal contributors included the headmaster of one of the best-known day schools of Britain, a university professor of the first rank, an eminent industrial scientific worker, and a vice-chancellor of a university famous as a centre of culture and learning.

As often happens in a discussion of such a broad topic as the education of men of science, there was no precise definition of many of the terms used. The term 'man of science' is often used to connote a member of that small but highly distinguished band of investigators who lead in the paths of discovery. To others it means one of that large body of scientific craftsmen, who, having had a university training in science, earn their livelihood by the pursuit of science or the application of science, whether in the universities, or in industry, or in Government laboratories, or elsewhere. It is necessary to distinguish clearly between the needs of the specialist, and the needs of the average scientific worker. The methods in use at the schools and universities of Britain have in the past created scientific leaders of the first magnitude, and the virtues of such a system cannot be lightly discarded. On the other hand, it may well be argued that the courses designed primarily for specialists are not necessarily well suited to the needs of the body of scientific workers of more average ability.

Scientific workers of the first rank are usually men of wide interests and cultural attainments. Nothing could be more specialized than the present training of mathematicians, and yet the ablest of them are often men of great literary ability. Eddington and Jeans were outstanding examples. In every branch of science there have been leaders who have attained distinction, not only in their subject, but also in the art of lucid and concise exposition.

It may be instructive to inquire why it is that the man of science of the most gifted kind is also usually a man of culture, for this may help in considering the education of those of more limited talents. Having ability of an unusually high order, with all that that implies of alertness of mind, quick understanding and capacious memory, he develops as a rule wide and intense interests. It may be that these are associated with, or arise from, his predominant life's work, but all life, all Nature, arouses his penetrating curiosity. Finally, being quick in thought and efficient in action, the greatest scientific worker contrives also to have leisure. The qualities of ability and interest, together with leisure, lead to a fund of general knowledge and culture which we describe as education; and perhaps it is the gift of ever-widening interest which matters most.

Implicit throughout the discussion was, however, the assumption that it is the education of the good, competent, but not exceptionally brilliant man of science which gives cause for concern. In this category we may include all who are professionally engaged in the pursuit of science, whether in teaching, or in research, or in the manifold applications of science to industry.

Education is a more difficult term to define. It is easier to say what it is not. It is not simply the acquirement of knowledge or the filling of the mind with facts, or even familiarity with a particular culture. It may be more an attitude of mind or the habits of thought engendered by study, or again it may be a cultivation of personal aptitudes and abilities to enable a man to live a useful and satisfying life. Sir Henry Dale in his opening remarks said that education should provide not only a training adequate for the technical needs of a man of science in his profession, but also should fit him for his part as a good citizen and an acceptable member of a cultured community. He stressed also the importance of the power of communicating thought and the discipline of lucid and accurate composition.

The point of view of the schoolmaster was expressed by Dr. Eric James, the High Master of Manchester Grammar School, who said that the task of the schools is a threefold one: first, to maintain the quality of the specialist knowledge of our potential scientific workers; second, to see to it that they are aware of the social relevance of their work; and third, to ensure that they are people with the fullest general education. He was of the opinion that a man who has specialized in one science at a university, and perhaps done some research in it, is usually a better teacher not only of that but also of other subjects than one who has attempted to bring several subjects to degree standard. Moreover, he has often had leisure for interest in other subjects, which have contributed to his wider education. He thought it was no answer to the problem of providing a general education to insist that all men of science should reach a certain standard in a literary subject; in, for example, a modern language. What is required is imaginative teaching of such subjects as history, divinity, or even elementary philosophy, so that the boy or girl should be led to think and read and argue for himself.

Sir Lawrence Bragg described the kind of training which science students receive at present in British universities and said that, while a large proportion of science students leave the university at the completion of a three- or four-year course, many of those adopting science as a profession now spend a further three years in research, so that the total time spent at a university may be six or seven years. The object of the university course should be to train a student in certain fundamental mental disciplines, so that when later in his career he is confronted with new problems, he may fall back on the old lines of thought and use the conceptions he has acquired, even though most of the factual information he learned may have been forgotten. In many respects university courses had in the past been successful, particularly in providing leaders in pure science, but serious criticism has been advanced that the present generation of scientific workers has had too narrow and specialized an education. It is also a frequent complaint of the industrialist that scientific recruits are unco-operative and intolerant and lacking in a knowledge of the world.

Sir James Irvine thought that some of the defects of the present method of training could be overcome, or at any rate mitigated, during the post-graduate years, particularly if there was the right relation between student and supervisor. It was a time to fill in gaps in education both on the scientific and literary sides. The writing of scientific reports could be made an important part of the education of a scientific worker. He favoured the study of a language, preferably Latin, to assist in the art of writing and speaking the English language. He also advocated an interest in poetry as a stimulus to the imagination and a counterweight against materialism.

The point of view of a man of science in industry was expressed by Sir Arthur Fleming, who dwelt on the qualities of mind and character which, in addition to technical proficiency, are necessary for success in industry. He mentioned qualities of sound judgment, courage and the capacity for leadership. He made the point that a considerable number of science graduates who enter industry ultimately change from purely technical work to other tasks, where their scientific training, while still of importance, becomes secondary to other qualities. Reference was made to a recent survey of more than a thousand science graduates who had passed through the post-graduate training scheme of a large engineering firm. It was found that at the age of thirty-five, fifty per cent of the men were no longer engaged primarily in technical work, while at the age of forty-five the proportion had risen to more than seventy-five per cent. This means that it is important for the ordinary science graduate to possess, or to develop, the qualities which will enable him to fit into the important and responsible positions, open to scientific workers, offered by a large industrial organisation.

In the open discussion which followed, a representative of the Scottish Branch of the Science Masters' Association stressed the importance of training character as well as developing technical skill. He said that since ideals are more readily caught than taught, it is necessary that university science graduates of the highest quality should enter the teaching profession. Universities should encourage a proper balance in schools by limiting the knowledge demanded of entrants and should take character into consideration.

Reference was made by Dr. Maxwell Garnett to the work of a committee of the British Association on university education and to the need for an inquiry in Britain similar to that which had produced the Harvard report on "General Education in a Free Society".

There seemed general agreement among all those who contributed to the discussion that all is not well with the education of the man of science; but where precisely the defects lie, or what the remedies should be, are matters on which there are conflicting opinions. If the objectives were agreed, the means would not be lacking to attain them. Part of the difficulty arises from the differing views as to what constitutes education. There is often confusion between education and the acquirement of knowledge. As was pointed out by Dr. Eric James, there is a tendency to assume that a general education can be obtained by a suitable arrangement of the school time-table. He was surely on the right lines in stating that the aim should be to introduce to boys at school some of the problems of life and society in such a way that they will want to read and think and argue for themselves. In other words, we should try to promote their interest in the wider field of knowledge by using as a central nucleus the scientific knowledge they already possess. Could not history—and in some cases literature—be taught from this angle ? Social history is as fascinating to the scientific worker as to the historian, and in this respect Trevelyan's recent book provides an admirable example of what can be done. This approach to history provides contacts with daily life and experience, and shows the effect of discoveries in science on the daily lives of mankind.

Everyone seemed agreed that a reasonable competence in the art of self-expression, both of an oral and a written kind, should be regarded as a necessary qualification of a man of science. This implies wide reading and a rich vocabulary, so that ideas may be expressed clearly and vividly in simple language without an excessive use of technical jargon. But, as Sir Henry Dale said, before we put too exclusive a faith in extra scientific studies as the means to this end, we ought to consider whether present faults may not be mainly in the teaching of science itself. The power to give clear and simple expression to a result or a conception requires, in the first place, the ability to think clearly about it; and teachers of science have admirable opportunities of training their pupils in the art of expressing what scientific knowledge they possess. Science can provide many examples of men who without the advantages of a formal education have produced writings on science which are none the less admirable as literature. The teaching of science can be made in itself cultural.

The discussion brought out that other traits of mind and character are necessary for success in the active and developing fields of scientific endeavour. How are qualities of sound judgment, courage or leadership to be developed in the course of education ? To some extent they are probably innate and can only be developed and fostered by training. Judgment involves experience and the capacity to profit by experience. Leadership involves self-confidence and the ability to inspire others. These qualities are not likely to be engendered by study but more by contact with affairs and association with one's fellows.

Education must accordingly provide for social contacts on an adequate scale. Schools and universities cater in differing degrees and with differing success for these requirements. There is a widespread feeling that fuller facilities for residence in the universities are a necessary development to meet this need. The severe selective competition of the class-room tends to produce intense individualism. This often becomes more pronounced in post-graduate work, when there is an understandable eagerness to make individual contributions to the field of knowledge and a corresponding desire for personal recognition. It is all the more necessary that there should be counterbalancing influences in a well-ordered communal life for undergraduates and post-graduate students. We have to reconcile the virtues of individualism with a spirit of co-operation, for excessive individualism may lead to difficulties in a large organisation.

The education of the man of science must be such that it gives him points of contact and common interest with his fellow men, and at the same time permits him to reach forward to the limits of knowledge in his own field. In this sense it must provide ever-widening expansion in the horizontal plane, the plane of general experience, and at the same time provide the path to the heights of specialist knowledge.

The discussion directed attention to important problems. It raised more questions than it answered, and these are the concern of school teachers, university teachers and industrial scientific workers alike. There is need for closer consultation between all the principal parties concerned. The discussion arranged by the British Association will have achieved its purpose if it stimulates further exchange of views and leads to the setting up of competent, representative bodies to study the problems involved. Thus may we hope to advance along the road of educational progress for the benefit of the next generation of men of science.

UNIVERSITIES OF GREAT BRITAIN

THE "Conference of Home Universities", which met in the Senate House of the University of London on September 26 and 27, was the second which had been called together at the initiative of the Vice-Chancellors' Committee. The first conference, which took place in 1946, was of a tentative nature (a report has just been issued: Universities Bureau, 8 Park Street, London, W.1. Pp. 76. 1s.); but the present meeting was on a larger scale and had a wider range. Its purpose was to test the value of discussions between the administrative authorities of the universities and the representatives of the teaching staffs, on questions affecting the policy and the development of university education. It was attended by pro-chancellors, vice-chancellors, principals and by representative professors and lecturers from all the universities and university colleges of the United Kingdom, by members of the University Grants Committee and by representatives of the Association of University Teachers and the Scottish Association of University Teachers.

Such a gathering may legitimately claim to be a model or blue-print, or whatever the current phrase is, of a university parliament. When one considers the independent origins of the universities of the United Kingdom, their diversity of age and constitution and their jealously guarded tradition of autonomy, it is a step of no small importance to higher education that they should thus assemble the various elements in their hierarchies to discuss problems of the day which affect them all in common and may influence their future.

Some may be tempted to regard such an undertaking as another manifestation of the passion for planning, from which few interests are to-day immune, but that would be a complete misunderstanding of the spirit and intention of the Conference. There was no suggestion of any move towards uniformity, nor even of any special expectation or wish for unanimity. Everyone concerned recognizes that each university must continue, as in the past, to work out its own salvation in its own way, but these conferences may enable it to take advantage of the benefits of consultation and the pooling of experience, in which lie the true strength of democracy.

The first session was devoted to the question of "The Expansion of the Universities". The chairman was, appropriately, Sir Alan Barlow, second secretary of the Treasury and recently chairman of a Government committee the report of which, urging an increase in the output of scientific workers by 100 per cent in the next ten years, has aroused so much interest and controversy. The vice-chancellors have themselves issued a commentary on this report, demonstrating the difficulties which stand in the way of expansion on such a scale, and Dr. R. V. Southwell, rector of the Imperial College of Science and Technology, dealt with some of these in his address. He believed, he said, that the two major questions around which most of the discussions on the Barlow Report had centred were at present insoluble. These were: (*a*) the extent of the demand from industry for university graduates; and (*b*) the reserve of intelligence of university level available to increase the number of graduates. He considered that material shortages would, in any event, preclude undue expansion in the immediate future, and that we might beneficially confine our discussions to certain non-material questions with which a policy of expansion confronts us, and which must be resolved if expansion is to take place. He instanced the maintenance of academic standards, the balance of subjects in the faculties and the task of the universities in technology.

The discussion which followed tended to emphasize the present material difficulties; but Lord Simon of Wythenshawe and other speakers agreed with Dr. Southwell's conviction that university training of men of science and technologists is an essential part of the production drive and that it must rank among the highest priorities if production is to flourish. Lord Eustace Percy (Durham) pointed out that some universities have already gone so far in permitting expansion that unless greater Government support be forthcoming they would be forced to reverse the movement.

Prof. R. Pascal (Birmingham) directed attention to the importance of the balance of studies, and urged that expansion in the arts faculties should be governed by an authoritative estimate of the demand for their graduates, if we are to avoid the evils of over-production in that direction.

The second session turned to the question of "The Basis of Selection of Students", under the chairmanship of Prof. F. C. Bartlett, professor of experimental psychology at Cambridge. The discussion was opened by Prof. Godfrey Thomson of Edinburgh, who brought forward arguments based upon intelligence tests, which tended to show that the university population could be doubled without a fall in standards, provided that all those of adequate intelligence outside the universities could, in fact, be brought in, and that efficient selection were operative. He presented the detailed results of a number of investigations; but was careful to emphasize the somewhat precarious nature of the data. He also recognized that there is a fairly large percentage, among those of adequate intelligence, who do not want a university education and would refuse it even if liberal financial assistance were provided.

Dr. J. F. Mountford, vice-chancellor of the University of Liverpool, followed with a consideration of the technique of selection of students. He pointed out that any technique of selection must operate against a background of theory respecting the kind of persons we want in universities and of information about the national requirements, both of which are lacking. He reviewed the value of examinations, recommendations, school records and intelligence tests as means of selection and showed that all are faulty, though he suggested that more use might be made of a carefully devised system of school recommendations, in regard to which we might learn something from American practice. Interviews, while sometimes useful, are tricky and are impossible where very large numbers are concerned. Dr. D. R. Pye, provost of University College, London, gave an interesting account of a system of intelligence testing, requiring relatively little time, which has been experimentally adopted for medical entrants at that College. The chairman stressed the widespread use of intelligence tests, apparently successfully, by American universities.

The final session, under Sir Hector Hetherington, vice-chancellor of the University of Glasgow, considered "The Proposal to Establish a Representative Universities Council". The discussion was opened by Lord Simon of Wythenshawe, chairman of the Council of the University of Manchester, who pointed out that a powerful dual planning organisation, in the University Grants Committee and the Vice-Chancellors' Committee, is already in existence, with a good record of work accomplished. He put the question: What would be the functions of the new body? Prof. S. Brodetsky (Leeds) and Lord Chorley (London School of Economics), on behalf of the Association of University Teachers, both supported the proposal for a new council, which would include representatives of the university teachers and hence might have a realistic approach to its problems. Some apprehension was expressed by other speakers lest the council should trespass on the liberties of the universities, and Sir Walter Moberly made it clear that the University Grants Committee did not welcome the scheme. The chairman then ably weighed up the arguments and concluded by advising that there should be a continuation of these annual conferences, perhaps associated with preliminary regional conferences, rather than a new body. With this suggestion the Conference concurred.

The overall picture drawn by the Conference, of the universities of the United Kingdom between the upper millstone of Government pressure to expand and the nether millstone of crowded entries, creaking with overstrained machinery and ringed by shortages, was not encouraging, and showed how much need there is for the continued consideration of their situation by representative conferences.

The criticism might be levelled at this, as at many other conferences, that there was a tendency to skate round the fundamental issues, and Prof. Bartlett's challenge to consider the type of man we want to turn out from the universities was unanswered. The Conference was not ready for it; but, after all, it is still in the experimental stage, and greater experience will no doubt bring greater potentialities. Practical-minded people expect workaday results in the form of resolutions, appeals, protests and the like; but these things, whatever value they may have, are not to be looked for from a conference the first aim of which is the free exchange of ideas between men of common interests, who would never otherwise meet together. In fulfilling that aim the experiment may be pronounced successful, and we may look with hope for its further development.

Grateful thanks were expressed to Mr. J. F. Foster, secretary of the Universities Bureau, who organised the Conference, and to the University of London, which was host for the occasion.

R. C. McLean

CLEANED PICTURES AT THE NATIONAL GALLERY

By Dr. H. J. PLENDERLEITH

The Exhibition of Cleaned Pictures (1936–47) which opened at the National Gallery on October 9 is of unusual interest. Some seventy odd masterpieces are exhibited and all of them have been cleaned since the autumn of 1936. They are displayed for the first time without glass, on clean walls with auxiliary fluorescent illumination. Documentation is made available relating to the history of the pictures, in particular to their preservation and to any new facts revealed by cleaning: there are photographic records, studio reports and, from the laboratory, radiographs and scientific data collected in the course of diagnosis or for the purpose of making permanent records before, during and after cleaning.

The exhibition is served by a catalogue which explains the conditions in detail. The foreword by the Director of the National Gallery sketches the history of the national collection and shows how cleaning policy has varied since 1824, the date of foundation; and it outlines the main controversies (three in number) which have arisen on the subject of picture-cleaning during this time. In 1853, a Select Committee of Enquiry of the House of Commons put an end to the evil practice of applying to the pictures a varnish containing boiled oil. This varnish on ageing provided the golden colour which has too long been considered in the public mind to be the stamp of an old master. The old masters themselves have something to say on the matter—Rubens, Hogarth, Reynolds and Constable. They appeal with one voice for the protection of their works against whatever factors cause the yellowing of paint, and in doing so place a serious responsibility on posterity.

The exhibition is frankly experimental in character. While picture-cleaning is the central theme, the opportunity has been taken to stimulate interest in other aspects of practical curatorship. The visitor is introduced to some of the problems of preservation, storage and exhibition as they exist in the post-war National Gallery, and led to appreciate something of the care and control that goes into the safeguarding of our national patrimony of art.

Picture Cleaning

For many, the idea of cleaning pictures must be novel. It arises generally from the necessity of removing old varnish which has become yellow, shrunken and hardened, in which condition it causes a misrepresentation of the original colour and promotes cracking and the eventual disintegration of the underlying paint film. There is general agreement that the cleaning of pictures in the interests of their survival is an unfortunate necessity. Cleaning is followed by restoration, and this may mean anything from spotting out lacunæ caused by the flaking of old paint, to replacing a rotten canvas or panel by a fresh support. After restoration the picture has to be re-varnished, and this is carried out with the two-fold object of protecting the surface and of bringing the optical quality of the work, so far as possible, to the key intended by the author of the painting.

The resin selected for making picture-varnish is exclusively mastic: this is dissolved in turpentine without the application of heat. A coat of mastic varnish may remain protective for about fifty years under museum conditions, by which time it usually requires replacement. It will seem strange that such an impermanent varnish is preferred, and there is undoubtedly need for research in this direction. The advantage of mastic is that, irrespective of its age, it can be removed, with ease, by solvents which have no softening effect on the underlying paint film—a fundamental requirement of any varnish designed for artistic purposes. No permanent varnish is as yet known which possesses this property and is satisfactory in other respects.

During the present century, the incidence of cleaning at the National Gallery has been very irregular. For a variety of reasons, less than one picture a year was cleaned between 1900 and 1933, and thus there are large arrears of work requiring urgent attention. The war years during which the pictures were in exile provided an excellent opportunity to make up leeway with the minimum of inconvenience to the public. But it has been possible to treat only the most urgent cases: arrears of cleaning still continue to give rise to official concern.

Standard of Criticism

"The purpose of the exhibition," states the catalogue, "is not only to do justice to the cleaned pictures, but by extending the knowledge of their condition to bring about a higher standard of criticism." It is recognized that public criticism is important to the vitality of any picture gallery; and thus the present exhibition, while providing data for a reply to points of controversy which have been raised in the Press, is designed at the same time to stimulate interest in technical matters and to encourage criticism to develop along constructive lines so that its highest aims may be served.

Can controversy be avoided, it may be asked, when the issue is one of both fact and feeling, condition and appearance, and where there must be, inevitably, ample ground for antagonistic points of view? The answer is that it certainly cannot, and this is, perhaps, all to the good. But in the special case where criticism depends upon incontrovertible fact, whether ascertained or ascertainable, the fact must be recognized and accepted by the critic, otherwise his criticism falls to the ground and does credit to no one.

The significance of the present exhibition is its contribution to factual evidence: we have, in this age, methods of recording facts and of non-destructive testing either undreamed of in a previous generation or refined to the extent of being precision instruments in the hands of the expert—methods of collecting data which can be used in turn for testing the validity of criticisms, or for revealing imperfections in the technique of cleaning and restoration. It is a large step from the 'make do and mend' policy of 1824 onwards to the techniques advocated by the International Conference of Museum Experts, Madrid, 1934[1]. If one studies the history of conservation, one must be impressed by the far-reaching developments in both diagnosis and treatment. Unless criticism is prepared to advance in sympathy, it must lose, inevitably, in significance.

Scientific Inquiry

In the present age, the laboratory is as important to curatorship as is the library, and the National Gallery is fortunate in possessing a laboratory well-equipped for physical investigations, and already of international repute; and shortly to be extended in scope so that chemistry can also play its part and make contributions to the preservation and study of paintings. The value of the laboratory lies in the objective character of scientific inquiry.

For example, allegations concerning damage to Rubens' "Chapeau de Paille" were shown to be fallacious by the microscope and micrometer. Small passages of greenish-blue colour alleged by a critic to be all that remained of Rubens' original background (which, it was suggested, had been removed by drastic cleaning) were shown to underlie the main blue background by at least 0·02 mm., thus vitiating the suggestion. Rubens had overpainted this greenish-blue to eliminate much of the green; but this, of course, could not be appreciated until, in the course of cleaning, the removal of yellowed varnish allowed the eye to differentiate between blue and greenish-blue. The change in appearance is merely the revelation of truth. More is now known of Rubens' technique, and a certain mental adjustment is required to bring this latest phenomenon within our conception of Rubens' studio method. When the facts are digested, parallels are discoverable in other work by the same master, as the catalogue points out.

The value of soft X-rays in the study of painting is demonstrated by the quality of the radiographs on exhibition. Changes in colour can be followed by readings taken on a tintometer: cleaning swabs can be spectrographed or submitted to chemical analysis; and photographic recording by ultra-violet or infra-red illumination or by the use of coloured filters can add still further to the stringency of the control of cleaning operations. Photo-micrographs and -macrographs play their part.

Cleaning and Restoration, Good and Bad

A photograph of the forehead of the (restored) Velazquez "Philip IV", taken at about × 4 diameters, is shown in the exhibition. On comparing this with a similar photograph of the picture after cleaning and before restoration, it is clear that many tiny lacunæ have been 'in-painted', that is, restoration paint has been prevented from overlapping the original. The work is done superbly well: the art of restoration has developed with the means of controlling it. In former days over-painting of damaged areas was the rule (compare photograph of the forehead of "Philip IV" before cleaning); and it was even the case that coloured varnishes (anathema to-day!) gratified the æsthetic senses of our predecessors. It need scarcely be said that tinted varnishes were much in favour with the dealer and restorer, in their time, as they served to conceal imperfections of condition and technique.

In some circles the idea still persists that in cleaning a picture there is a positive virtue in avoiding the complete removal of the old varnish, this being claimed as a mild form of treatment. It is a specious argument, and the practice is only in favour in commercial *ateliers* where saving in cost is a factor or where there is lack of confidence or ability on the part of the restorer. It is to be condemned for the following reasons. First, because the use of feeble solvents necessitates using friction, and the rubbing of the surface of the painting tends to remove ridges of paint in the brush-work or crackle system. The hollows of the impasto and the cracquelure tend, inevitably, to become filled with a brown residue consisting of the least soluble constituents of the old varnish. There is this, also, to be said, that a picture so treated will speedily darken to the point of requiring re-cleaning, and the net result is that the incidence of cleaning is increased. Residues of the old varnish may well promote crystallization of the new. The practice of treating pictures along these lines cannot be too strongly condemned. One admits, however, with reluctance, that circumstances may occasionally require a compromise to be made. When this is so it can only be in favour of dark passages of colour: from light pigments and bright colour, all of the old varnish must be completely removed, and the degree of success of the operation can be followed in the laboratory by examining the painting under screened ultra-violet illumination, when the old resin residues are seen to fluoresce unmistakably.

Atmosphere and Stability

While pictures are re-conditioned by cleaning and restoration, their preservation is entirely dependent on the conditions of humidity and temperature in the picture gallery.

When humidity and temperature are uncontrolled, the day and night changes occasion rhythmic movements in the panels and canvases. These may be slight; but in the aggregate they have a deleterious effect on the stability of the paint layer. A consequence is the appearance of blisters in the paint, caused usually by cleavage between the ground and the support, and in the course of a year many are discovered and 'laid' by competent craftsmen. If undiscovered, the next stage is fracture and exfoliation of the paint, necessitating more serious treatment. Extreme atmospheric conditions or changes of condition are liable to cause catastrophe, such as disruption of the constituent planks of Holbein's "Ambassadors" panel (February 1895), or the splitting of Rubens' great "Château de Steen" (January 29, 1947).

It took experience of the war-time repository to bring out the fact that under controlled conditions of humidity and temperature ('conditioned air') no blisters form; there was practically no maintenance work of this kind required at Manod Quarry[2] in the course of years. The moral is obvious and of the greatest significance to the preservation of paintings: conditioned air must be accepted as essential for picture galleries. In the national collection, which is so rich in large Italian panels, a grave responsibility rests upon all who realize what is at stake. This is understood and accepted by the authorities, who, with the help of the Ministry of Works, have improvised a 'hospital' behind the scenes, and here by the aid of primitive controls the relative humidity can at least be held in check. By this means a floating population averaging some thirty 'ailing' pictures is saved, temporarily, from exposure to the more extreme climatic conditions of the public galleries.

It is with relief that we learn that a scheme for installing conditioned air in the National Gallery is in being. The apparatus exists already on the site. Plans have been approved for the first experimental section, and we can look forward to the coming of an era—let us hope it may be soon—when the building will be worthy of its great collection of pictures, cleaned by the enlightened methods of to-day, so that all in their generation may enjoy the work of the old masters as they themselves would have wished.

HYPOTHETICAL ALTERNATIVE ENERGY SOURCES FOR THE 'SECOND MESON' EVENTS

By Dr. F. C. FRANK, O.B.E.

H. H. Wills Physical Laboratory, University of Bristol

In the paper by Lattes, Occhialini and Powell*, it is shown that cosmic ray mesons coming to the end of their track in a photographic emulsion rather frequently give rise to a secondary meson of kinetic energy about 4 MeV., and no other visible particle. This observation appears to demand for its interpretation the existence of two sorts of meson, the source of the observed kinetic energy of the secondary residing in the mass difference between the two. In view of the importance of this conclusion, we have tried to consider all reasonably imaginable processes to explain the observations without introducing a new elementary particle; processes, that is, in which the energy is derived from the material of the photographic emulsion instead of from the meson. Reasons are given below for the confident rejection of all such processes.

It is concluded that there is no energy to be gained, from elements present in substantial quantity in the photographic emulsion, from the following processes:

(*a*) Induced β- or K-capture processes; on grounds of known mass defects for the lighter nuclei, and systematic principles for the heavier nuclei present. There should be energy (though not enough to explain the observations) to gain from such processes from K^{40}, Rb^{87}, Lu^{176}, Os^{187} and from one each of the pairs In^{113}, Cd^{113}, Sn^{115}, In^{115}, Te^{123}, Sb^{123}; none of these is present in substantial quantity. It is improbable that any natural nucleus possesses a more stable adjacent isobar not discovered in Nature.

(*b*) Induced emission of single nucleons: on grounds of known mass defect for the lighter nuclei and systematic principles for heavier ones; such processes, from naturally existing nuclei, always absorb energy.

(*c*) Induced α-emission: excluded for the lighter nuclei by known mass-defects. Not excluded for the heavier nuclei, since mass defects are not known with sufficient accuracy, and by the Geiger–Nuttall relation the life-times of low-energy α-emitters are too great for detection. However, with no heavier nuclei than silver present, energies greater than about 2 MeV. are excluded by this consideration, because they would lead to spontaneous decay at a detectable rate. Moreover, the Coulomb repulsion from a medium-heavy nucleus would assuredly give the α-particle sufficient energy to make a visible track.

---

* See *Nature*, 160, 453 and 486 (1947).

(*d*) Induced fission: once again Coulomb repulsion would assuredly produce a visible track from the fission fragments, and it is inherently improbable that a meson could activate the process, say in silver, the only element which comes in question from the point of view of availability of energy.

(*e*) Processes with change of charge by 2, for example, of the type

$$At_Z^A + Y^- \rightarrow At_{Z-2}^A + Y^+,$$

where Y^- and Y^+ denote negative and positive mesons. It is to be expected that this process, if it can occur, would yield energy from about half the nuclei which possess stable isobars of charge diminished by 2. In the case of Zn^{64} going to Ni^{64}, measured mass defects indicate an energy yield of 9·8 ± 3 MeV. The conditions for this process are not satisfied by any nucleus present in substantial quantity in the photographic emulsion, namely, by isotopes of hydrogen, boron, carbon, nitrogen, oxygen, silver, bromine, iodine and sulphur; of these only S_{16}^{36}, the rarest (0·016 per cent) of the isotopes of sulphur, which is itself present only in traces, has a known stable isobar A_{18}^{36}. That is in the wrong direction, requiring the improbable converse process starting with a positive meson.

(*f*) Induced decay of naturally persisting nuclear isomers: this would imply the existence of isomers with life-times about 10^{12} times as great, and stored energies about ten times as great, as any yet known—a very improbable combination.

This seems to exhaust the possibilities among processes of nuclear degradation. On the other hand, it needs more consideration to exclude the possibility of processes of nuclear build-up, in which a proton is added to some other nucleus: such processes are almost all exothermic. The possibility of such processes arises from the special properties of the combination of proton and negative meson, which may be called a mesonic hydrogen atom, or an excited neutron, at choice.

A meson stopping in the emulsion loses kinetic energy from, say, 100,000 eV. down to 2,000 eV. in a fraction of a micron. This may occur either in silver bromide, or in gelatine, with comparable probability. In the latter case it is very likely to be in the neighbourhood of a proton, of which there are about twice as many as all other nuclei together in the gelatine. It should then, at first, enter a hydrogen-like orbit about the proton. The resulting compact neutral atom (radius, in the 'Coulombic ground-state', about 1/200 of the Bohr radius, thus 2·6 × 10^{-11} cm., and binding energy about 200 times that of a hydrogen atom, thus 2,700 eV.) should appear, from distances exceeding 10^{-10} cm., like a slow neutron. It should be able to pass freely through the electronic clouds of other atoms, and approach close to nuclei, without Coulomb repulsion. Indeed, the polarization of the mesonic atom in the field of a second nucleus should lead to an initial attraction.

The most probable next step would appear to be the capture of the meson by the nucleus of higher charge, and repulsion of the proton. There should, however, be a non-vanishing probability that the proton is captured, and the meson expelled. In one case at least, namely, that in which the second nucleus is a deuteron, the probability of the alternative reaction should be high. For by analogy with the hydrogen molecule-ion, H_2^-, the combination of deuteron, proton and meson should be stable in respect of Coulombic interactions with an internuclear separation of $10^{-8}/200 = 5 \times 10^{-11}$ cm. At this distance, with a very low Gamow barrier, the two nuclei should very readily unite, the meson acquiring kinetic energy by what may be described as 'internal conversion'. Thus, formally, we should have the reaction:

$$\begin{array}{llll} H_1^1(e^-) + Y^- & \rightarrow H_1^1(Y^-) + e^- & + & 2{,}700 \text{ eV.} \\ H_1^1(Y^-) + D_1^2 & \rightarrow H_1^1 D_1^2(Y^-) & + & 500 \text{ eV.} \\ H_1^1 D_1^2(Y^-) & \rightarrow He_2^3 + Y^- & + & 5{\cdot}46 \text{ MeV.} \end{array}$$

It is highly improbable that the small amount of deuterium present in the normal emulsion could account for the observed phenomena. The corresponding process with a second proton (forming a deuteron, since He^2 is not stable) requires the emission of a positron and neutrino which, between them, would take most of the 1·43 MeV. available, which is in any case insufficient. With heavier nuclei the details of interaction are more complicated, since, among other considerations, there will only be binding in the molecule-ion while it is in an excited state.

The mesonic hydrogen atom will be attracted to a second nucleus by virtue of polarization. Some energy can be dissipated to form the molecular combination, by Auger effect, which will cease to operate when the nuclei and meson are well within the K-shell of electrons. The combination dissociates when the meson falls by a radiative transition into a level in which it is concentrated around the nucleus of higher charge. The time taken for this radiation should be of the order $(hc/e^2)(\lambda/r)^2(1/\omega)$, which is about $10^6 Z^{-2}$ periods of the emitted radiation (as in hydrogen-like spectra) whether we are dealing with mesons or electrons. The characteristic frequency should be 200 times that of the corresponding electronic spectrum, that is, say, $10^{18} Z^2$, and the frequency of molecular vibration $(200)^{3/2}$ times that of electronically bound hydrogen compounds, that is, about 3×10^{17}. Hence, we estimate the life-time of the bound state as about $10^{-10} Z^{-4}$ sec., or about $3 \times 10^7 Z^{-4}$ periods of oscillation of the mesonic molecule-ion.

The Gamow barrier to be penetrated by the proton extends from the internuclear separation in the excited molecule-ion, r_1, to the distance at which the nuclei make contact, r_0. The meson still provides some screening within this distance, and we take the potential energy to be $E = (Z - 1)e^2/r$. We estimate r_1 as that distance at which the polarizing action of the second nucleus, on the mesonic hydrogen, regarded as linear with field strength, produces an equivalent displacement of the meson equal to its Bohr radius, $a_Y = 2{\cdot}6 \times 10^{-11}$ cm. Thus, $r_1 = 3a_Y\sqrt{Z/2} = 5{\cdot}5 \times 10^{-11} Z^{1/2}$ cm.: r_0 we take as $1{\cdot}45 \times 10^{-13}(A^{1/3} + 1)$ cm., where A is the mass number of the second nucleus. Then, if we write $\lambda^* = h/\sqrt{2M(E - E_0)}$ (where M is the mass of the proton) and neglect the initial kinetic energy E_0, the transparency of the barrier to a proton wave should be of the order

$$\exp\left\{-4\pi\int_{r_0}^{r_1}(1/\lambda^*)dr\right\}$$

$$=\exp\left\{\frac{-8\pi e\sqrt{2M(Z-1)}}{h}\left(r_1^{1/2}-r_0^{1/2}\right)\right\}$$

$$=\exp\left\{-3{\cdot}33\sqrt{Z-1}\left(7{\cdot}4Z^{1/4}-0{\cdot}4\sqrt{A^{1/3}+1}\right)\right\},$$

which is about 10^{-27} for B_5^{11}. This, subject to considerable error, for example, from the uncertainty of r_1, expresses the probability that the proton will penetrate the barrier in one attempt. Multiplying by the number of oscillations before dissociation, we find the probability of penetration before dissociation to be 10^{-21} in this case. This result may well be in error by several powers of 10, but it appears that if the model is at all relevant, the chance of penetration is insignificant for all nuclei beyond the deuteron. The same calculation for the latter, neglecting the inner screening and so writing 1 in place of $\sqrt{Z-1}$, gives a penetration probability of 10^{-9} per vibration, so that penetration may occur in about 10^{-8} sec.

Specific forces of the meson have been disregarded. There is an obvious chance that it will suffer nuclear capture or destruction before the two nuclei can interact, the probability of which is reduced by the fact that the meson is in excited states throughout the period significant for this process. If, on the other hand, the mesonic forces lead to some closer union of proton and meson than we have considered (differing from a neutron), it might well react with any nucleus.

The energy available from proton adhesion is small (1·96 and 0·51 MeV. respectively) for the 'saturated' nuclei C_6^{12} and O_8^{16}. For nearly all other nuclei it is 5 MeV. or more. The next most common nucleus in the gelatine is N_7^{14}, yielding 7·3 MeV., which would account for the observations if the product, O_8^{15}, was formed with an excitation of about 3·5 MeV. Boron was also present in these emulsions, and could yield more than enough energy by proton adhesion, but in this case the most likely reactions liberate α-particles.

This process can in any case be rejected statistically. For a total of 380 mesons observed to stop in the emulsion, four secondary mesons have been observed, with at least 500 μ of secondary track in the 50-μ thickness of the emulsion, and mutually consistent in energy yield. Geometrical probability indicates that about thirty times as many events should have occurred, in which the secondary meson passed out of the emulsion earlier: it could then either go undetected or be indistinguishable from a proton. On the other hand, one should not fail to detect a projected length of 50 μ of the end of a meson track. Hence the four observed secondary mesons are representative of about 120 ± 60 (the limits expressing probable error) whereas the 380 mesons observed to stop should represent not more than about 900 actually stopping. (For randomly directed straight tracks ending at random depths in an infinite layer of thickness H, the statistical proportion of all tracks which end in the layer which have horizontally projected ranges within the layer exceeding R is $(\sqrt{R^2/H^2+1}-R/H)$. For $R/H=1$, this is 0·414. For $R/H>1$, it is well approximated by $H/2R$, but for $R/H\gg 1$, track curvature will reduce the proportion below this estimate.)

Thus it appears probable that the production of a 4 MeV. secondary meson occurs for 13 ± 7 per cent of the mesons stopping in the emulsion. Presumably only about half the mesons are negative, and only about half of these can form mesonic hydrogen atoms (since H comprises 40 atomic per cent of the whole emulsion): if we suppose the interaction with a second proton is weak, so that the mesonic hydrogen is most likely, and about equally likely, to be attracted to carbon, nitrogen or oxygen (1 in 8 of which nuclei, in the gelatine, is N^{14}), we have an expectation of about 3 per cent if *every* encounter of a mesonic hydrogen atom with an N^{14} nucleus leads to capture of the proton, and on every occasion there is 'internal conversion' of the liberated energy, producing a secondary meson of 4 MeV. Unconsidered factors are mostly unfavourable, so that even on the small number of observations it is statistically improbable that they represent this process.

A further consideration is that the simple theory leads us to expect a larger number of easily observable 2 MeV.—and possibly of ½ MeV.—secondary mesons deriving their energy from proton adhesion to C_6^{12} and O_8^{16}: though it is a simple and plausible addition to the theory to suppose that these reactions are relatively 'forbidden'.

It should be added that such processes may be of importance in other circumstances; if it is correct to suppose that mesons can survive for, say, 10^{-8} sec. in hydrogen-like orbits about protons, then there is a finite chance that a meson can induce a nuclear build-up reaction, causing the attachment of a proton to a deuteron. However, with two or more cosmic ray mesons in the field, the whole of our observational knowledge about mesons requires re-examination.

I am indebted for a number of discussions to Dr. H. Fröhlich and Messrs. Lattes, Occhialini and Powell.

Note added in proof. Later observations enable the 'corrected observed' proportion of mesons producing secondaries to be refined from 13 ± 7 per cent to 12·8 ± 2·5 per cent (117 ± 20 in 917 ± 70), thus increasing the confidence with which the hypothetical alternative process can be rejected.

OBITUARIES

Prof. T. David Jones, C.B.E.

It is with much regret that we record the tragic death of Prof. Thomas David Jones in a motor accident which occurred outside Amesbury on August 30.

T. David Jones was born of a mining family at Aberyskir, Breconshire, in 1900. He was educated at the Technical College, Swansea, and the University College, Cardiff. After the First World War, during which he served with the 17th Lancers, he resumed his studies at the University of Birmingham. He graduated, and passed the Colliery Managers' Examination in 1922, obtained his M.Sc. in 1923 and the Ph.D. a year later. He was then appointed to the mining research staff directed by the late Prof. J. S. Haldane. In this capacity, he carried out extensive investigations into mining conditions, spontaneous combustion, geothermic gradients and mine lighting.

In 1936, Prof. Jones was appointed to the chair of mining at the University College, Cardiff, and in 1939 he became director of research to the Monmouthshire and South Wales Coal Owners' Association, in which position he was responsible for intensive investigations carried out on the suppression of dust in coal mines. He was invited in 1946 to visit and advise the colliery engineers of Belgium and Holland on various mining problems, and earlier this year had carried out an extensive tour at the request of the Commonwealth Governments of Australia and New Zealand. In April of this year he was appointed to the chair of mining at his old University at Birmingham.

Prof. Jones was a member of many learned societies and institutions, most of which he served on their councils; he was actively interested in all schemes connected with mining education and training, and for many years he had been actively connected with the Order of St. John. He was made a Commander of the British Empire in January 1947; a Commander of the Crown, Belgium, in June 1947, and a Commander of the Order of St. John of Jerusalem in July 1947.

He had high academic qualifications, a broad outlook on life, and an intense interest in his fellow beings. His boyish enthusiasm, together with his great energy, made him an outstanding personality, endeared him to his colleagues, and fired all who came in contact with him with his own enthusiasm.

J. HOWARD GRIFFITHS

WE regret to announce the following deaths:

Mr. John Dower, author of the report on National Parks in England and Wales (1945), prepared for the Ministry of Town and Country Planning, on October 3.

Dr. Stephen Miall, for many years editor of *Chemistry and Industry*, on October 12, aged seventy-five.

NEWS and VIEWS

Education in H.M. Forces

Now that the Royal Navy, the Army and the Royal Air Force are beginning to assume a peace-time footing, education in those Services is being revised. The Services are anxious to continue effective liaison with civilian education authorities in organising and developing educational facilities among serving men and women. An Army Education Advisory Board and a Royal Air Force Education Advisory Committee, both representative of a range of civilian educational interests, have already been formed. All this will affect the Central Advisory Council for Adult Education in H.M. Forces which, under the able secretaryship of Dr. Basil Yeaxlee, and with the help of its regional committees, has worked hard throughout the War and since (in an advisory capacity) in providing the necessary liaison between Service and civilian education authorities and in choosing and supplying lecturers and other educators (in an executive role).

The Council and the three Services have therefore agreed in principle to the following proposals, subject to further consideration of details: (1) The universities should be invited to consider their extra-mural departments taking over the work hitherto carried out by the regional committees of the Council. (2) Advisory functions of the Central Advisory Council should now be discharged by the inclusion of some of its members on the new Army Education Advisory Board and the Royal Air Force Education Advisory Committee. The Admiralty hopes to obtain advice from former members of the Council on an *ad hoc* basis. Meanwhile, until the end of 1948, the Council should continue to function as such.

So far as the Council's executive functions are concerned, it is suggested that these should in due course be assumed by an inter-Services Executive Committee whose members will represent the Services, the Ministry of Education and other civilian educational interests. If the new proposals are eventually put into effect, their success will depend upon the goodwill of the Services and civilian educationists and others concerned. If Service education is to be accepted as an integral part of national education, then it is up to both Service and civilian personnel to work together. In this respect, responsibility will devolve on the universities and other civilian education institutes and authorities to see that whatever facilities, advice and other assistance they can give to all three Services must be given whenever required; on the other hand, the Services must recognize that if their educational work is to attain a high grade and be recognized by the soldier, sailor and airman as a real and effective part of the nation's educational scheme, then the Service educational authorities must collaborate as much as possible with their civilian colleagues and counterparts.

British Dyestuffs: Mr. J. Baddiley

MR. J. BADDILEY, for many years research director of Imperial Chemical Industries, Ltd. (Dyestuffs Division), retired on September 30. He was intimately associated with research in the dyestuffs industry throughout the whole of the period popularly known as the renaissance of British dyestuffs. A pupil of Prof. Green at the University of Leeds, Baddiley was appointed as research chemist in the company of Levinstein, Ltd., at Blackley in 1909, and provided the first example of departure from Mr. Ivan Levinstein's policy of employing only German chemists. At an early date he exhibited a flair for inspiring and leading other research workers, and during his first years of service to industrial chemistry he guided an ever-increasing team of workers who were charged with the task of putting British dyestuffs on the map. During this period he discovered a range of dyes designed to produce level (or even) shades on viscose rayon. When I.C.I. was formed, he was made a delegate director responsible for research in the group of dyestuffs manufacturers in the parent company. Dyestuffs research was concentrated at Blackley and, during Baddiley's tenure of office, grew tremendously, embracing also the fields of rubber chemicals, auxiliary chemicals, organic polymers and synthetic drugs. Dyestuffs, his first love, remained his favourite, however, and perhaps his greatest single achievement was the discovery, in collaboration with the late Mr. A. Shepherdson, of a range of dyestuffs for the colouring of acetate rayon. Baddiley's high reputation in the dyestuffs and dyeing industries was recognized when he was awarded the Perkin Medal by the Society of Dyers and Colourists in 1939.

U.N.E.S.C.O. Field Scientific Officer for Far East

Mr. Jan Smid has been appointed field science co-operation officer for East Asia and the Philippines of the United Nations Educational, Scientific and Cultural Organisation. He will leave shortly for Nanking. He is a Czechoslovak civil engineer, thirty-five years of age, who studied at the Polytechnic at Prague, and then worked in Paris, during 1937 and 1938, at the École des Ponts et Chaussées. Joining the Czechoslovak Army in France in 1939, he was wounded. In 1942, he made his way to Britain, via North Africa, and rejoined the Czechoslovak Army, serving until 1946, when he returned to Paris to work in the office of Prof. Caquot, the well-known French civil engineer, for whom he had previously worked during the period 1937–39. The Field Science Co-operation Office at Nanking is the third which U.N.E.S.C.O. has set up—the other two being at Rio de Janeiro and Cairo; the creation of a fourth, in India, will be proposed at the next General Conference of U.N.E.S.C.O., which meets in Mexico City next month. The function of these centres of scientific co-operation is to make available, in areas where the need is especially felt, information and help on scientific matters otherwise obtainable only with great delay or difficulty.

British Council Science Officer for China

Dr. H. V. Walters, chief physicist at Messrs. Dufay-Chromex, Ltd., has been appointed British Council science officer for China. He will be working with Dr. R. A. Silo, director of the British Council's Science Office in China. Dr. Walters, who is thirty years old, obtained his B.Sc. degree in 1938 while at the Imperial College of Science and Technology, London, and with a grant from the Medical Research Council remained at the College for a further year working with Dr. W. D. Wright on colour vision. In 1941 he joined Messrs. Dufay-Chromex, Ltd., becoming chief physicist in 1944, when he was placed in charge of research work on colour and optics, and of filter developments and photographic testing. In the same year he obtained his Ph.D. for papers on the trichromatic theory of vision and the spectral sensitivity of the fovea and extra-fovea.

United Nations Organisation

The British Society for International Understanding (Benjamin Franklin House, 36 Craven Street, London, W.C.2) has published in its *British Survey* (7, No. 14. 6*d.*) a teacher's guide to the United Nations. This guide explains the organisation and membership of the body and reminds readers of its purposes as set forth in the original charter signed at San Francisco in April 1945. The vital Security Council, which embodies the final aim of the whole organisation, has not yet found an acceptable plan for the use of armed forces to prevent or resist a breach of the peace. The Great Power veto is the crucial problem that faces the United Nations. So far, Great Britain has not used the veto, but the Soviet Union has done so repeatedly. The pamphlet contains a clear account of the powers of the Security Council and some of the problems that confront it. Another section gives brief accounts of the fate of issues that have already been placed before the Security Council with greater or less success. Finally, there is some account of the work of the Trusteeship Council and the various economic and social agencies of the Council; here some progress has been made. The pamphlet deserves a wide circulation.

Supersonic Speed Flight Investigation

British experiments upon supersonic speed flight, using rocket-propelled aircraft, were commenced on October 8, when a Vickers radio-controlled plane was flown at St. Eval, Cornwall. It was launched from a 'Mosquito' at about 35,000 ft. altitude, flew for 90 sec. and dived into the sea, according to plan. Information upon its behaviour was obtained by a technical observer watching from the launching 'Mosquito', photographs taken by a 'Meteor' jet-propelled aircraft, and radio signals upon speed, accelerations, pressures, etc., sent out automatically from transmitting apparatus on the experimental aircraft itself. It was hoped that a speed of more than 800 miles an hour would be attained, the speed of sound at that height being approximately 760 miles an hour. The results, mostly mechanically recorded for accuracy and to allow of working them out at leisure, will take about a week to analyse, but it is thought that the desired speed was reached.

The experiment was not entirely successful as the machine lost height more rapidly than was anticipated, probably due to what appeared to the observer to be instability in control. It was hoped that it would have climbed after its rocket engine commenced to function. Nevertheless, it will supply much valuable information, and has proved that this technique for such investigations is possible. Improvements in the design of further experimental aircraft, as a result of the analysis of these experiments, should make it possible to continue with radio-controlled aircraft without risk to human life.

Plant and Soil

An international periodical entitled *Plant and Soil* is to be issued towards the end of this year. It is to be devoted to the study of plant nutrition, plant chemistry and the related subjects of soil science, soil microbiology and soil-borne plant diseases. To meet the increasing demand for intensive crop production all over the world, quick exchange of the results of scientific research between the workers in this field is necessary; a number of outstanding scientific workers from different countries have therefore decided to collaborate in establishing the new journal. The editorial board includes the names of Gäumann (Zurich), Lundegårdh, Penningby and Melin (Uppsala), Hoagland (Berkeley), Koningsberger (Utrecht), Waksman (New Brunswick), Westerdijk (Baarn), and Virtanen (Helsinki). The journal will be published by the Martinus Nijhoff Publishing Company, The Hague. The subscription price is 7.50 dollars a year for one volume containing about 400 pages (four parts). Original contributions in English, French or German should be sent to the secretary of the Board of Editors, Dr. E. G. Mulder, Agricultural Experiment Station, Eemskanaal ZZ. 1, Groningen, Holland.

R.C.A. Technical Papers

The *R.C.A. Review* (Radio Corporation of America, R.C.A. Laboratories Division, Princeton, New Jersey) has recently issued volume 1 and volume 2 *a* of the Index to R.C.A. Technical Papers. Volume 1 covers the years 1919–45, and 2 *a*, 1946. It is planned to publish the yearly indexes, of which 2 *a* is the first, as sub-volumes, consolidating them under one cover at the end of five years as "R.C.A. Technical Papers" (1946–1950)—Index—Volume 2". Volume 1 supersedes "Index—Technical Papers by R.C.A. Engineers (1919–1939)" published by R.C.A. Institutes Technical Press in 1940. The Indexes contain substantially all the technical papers and books, published in English, on subjects in the radio, electronics and related fields, the authors or co-authors of which were associated with the Radio Corporation of America or its subsidiaries. Both indexes are similar in form. Bound in stout paper covers, they contain an explanatory list of abbreviations of titles of periodicals used in the Indexes, a chronological index, followed by a section in which the papers are arranged alphabetically according to title, an author index and a subject index. About 1,800 papers are listed in volume 1 and 200 in volume 2 *a*.

The Prehistoric Society

It would be difficult to find anywhere a publication on matters prehistoric more important than the *Proceedings of the Prehistoric Society*. Even during the War the editor, though in the R.A.F., managed from time to time to issue a volume. Now that the War has ended a really excellent number (New Series, vol. 12) has been published. The list of contents alone indicates the scope of the Society's interests: the relationship of bog stratigraphy to climatic change and archæology, by Dr. H. Godwin; seal hunting in the Stone Age of north-west Europe, by Dr. J. G. D. Clark; prehistoric investigations in British Somaliland, by M. C. Burkitt and P. E. Glover; the Levalloisian industries of Egypt, by Miss Caton Thompson; the late Bronze Age razors of the British Isles, by Prof. C. M. Piggott; prehistory in Ireland, 1937–46, by S. P. O'Riordain. There are also a number of notes, reviews and a list of members. There are many illustrations (one in colour), maps and diagrams. It is indeed pleasant to find that at least one learned society has managed to return to what is really a peace-time standard of publication.

New Seismological Observatories

The seismograph station at Honolulu has been transferred from the University of Hawaii to the new site of the Honolulu Magnetic and Seismological Observatory of the U.S. Coast and Geodetic Survey near Barbers Point, south-west Oahu. The new co-ordinates are tentatively reported as 21° 18·27′ N., 158° 05·76′ W. Recording began on October 17, 1946. One component of a Wood–Anderson seismograph was put in operation at Manzanita Lake in Lassen Volcanic Park, California, through the co-operation of the University of California and the U.S. Coast and Geodetic Survey.

American Physical Society Symposia

The May meeting of the American Physical Society, held in Washington, included a joint session with the American Meteorological Society; a two-session programme on "Low Temperature Physics", held under the sponsorship of the United States Navy; a two-session symposium on the "Physics of Surface Phenomena"; and a symposium on "Shock-wave Phenomena", presented by the Committee on Fluid Dynamics. As part of the general programme, two invited papers, one by Dr. Kathleen Lonsdale on "The Diffuse Scattering of X-Rays", and the other by Prof. S. A. Goudsmit, on "Why Germany did not get the Atomic Bomb", were given. Of the other invited papers, those dealing with the theoretical and statistical aspects of low temperatures were by J. C. Slater, Felix Bloch, and V. Johnson and K. Lark-Horovitz; and on the experimental side, by J. G. Daunt and H. Grayson, who discussed the properties of liquid helium II and superconductivity respectively. The full programme of the meeting and the abstracts of the 165 contributed papers appear in the July 15 issue of the *Physical Review* (**72**, 151–157).

Announcements

The Lord President of the Council has appointed Prof. P. I. Dee, professor of natural philosophy in the University of Glasgow, and Sir William Griffiths, chairman and managing director of the Mond Nickel Co., Ltd., to be members of the Advisory Council for Scientific and Industrial Research. Sir Lawrence Bragg, Sir John Lennard-Jones, Sir Andrew McCance and Sir Raymond Streat have retired from the Advisory Council on completion of their terms of office.

Dr. Norman C. Wright, director of the Hannah Dairy Research Institute, Scotland, has been appointed chief scientific adviser to the Minister of Food.

Mr. A. T. Green, director of research of the British Refractories Research Association and the British Pottery Research Association, has been appointed honorary general secretary of the British Ceramic Society in succession to the late Dr. J. W. Mellor.

Lord Rayleigh will open the new Physics Laboratories of the British Iron and Steel Research Association at Battersea Park Road, London, on October 22.

The fourth Dalton Lecture of the Royal Institute of Chemistry (Manchester and District Section) will be given by Dr. D. T. A. Townend, director of research, British Coal Utilisation Research Association, who will speak on "Fuel and Chemistry". The lecture will be delivered at the Albert Hall, Manchester, on November 27 at 7 p.m.; it is open to the public.

Research scholarships will shortly be awarded by the Royal College of Surgeons of England. There are two vacant Leverhulme Research Scholarships of the annual value of £400, with an allowance not exceeding £100 for expenses of research, tenable for one year but renewable. The awards, which will be made either as scholarships or as grants-in-aid, are for the investigation of biological or clinical problems of disease as it occurs in man, with a view to the extension of surgical knowledge. Facilities for research will be available in the Bernhard Baron laboratories of the Royal College of Surgeons in Lincoln's Inn Fields or at the Buckston Browne Farm, Downe, Kent. Applications must reach the Secretary, Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.2, before October 27.

The Society for Visiting Scientists (5 Old Burlington Street, London, W.1) is arranging a discussion meeting on "Law-making in Science" to be held on October 29 at 7.30 p.m. The chairman will be Mr. G. S. W. Marlow, and the speakers Sir Wavell Wakefield, M.P., Mr. A. R. Blackburn, M.P., and Dr. Cecil Gordon.

Erratum. Prof. J. S. Turner and V. Hanley, referring to the communication "Malonate and Plant Respiration" (*Nature*, Aug. 30, p. 296), write: "We were unable, owing to delay of mail, to correct the following mistake in the above letter. The correct figures are more in keeping with the interpretation put forward. Figures for undissociated malonic acid should read: *p*H 4·0, 6·5 per cent; *p*H 5, 0·6 per cent; *p*H 6, 0·02 per cent; *p*H 7, nil."

'Radiation Damping Theory' and the Propagation of Light

HEITLER and collaborators[1] have proposed a modification of radiation theory in order to remove the well-known divergencies. A variation of this procedure has been proposed by several authors[2]. We shall refer to these two forms as the time-dependent and the stationary form of the theory respectively.

In the time-dependent theory one starts from a modified version of the equations of field theory, in which a distinction is made between states in which energy is conserved and others, so-called intermediate states. The former are defined as those in which the unperturbed energy (omitting coupling terms) differs from that of the initial state, 0, by less than an amount, Δ, of the order of the line-width. It is assumed that the intermediate states differ from this energy by amounts large compared to the line-width and hence large compared to Δ.

In these circumstances, states of equal energy can either be reached from the initial state by a direct transition (states A, B) or by way of one or more intermediate states (states c, d . . .). The possibility of an indirect coupling by way of another state of equal energy is unimportant. The equations of radiation theory can then be written in the form of Heitler's equation (I′) which, in the conditions envisaged, is still practically identical with the usual equations. The essence of the damping theory is then to omit from (I′), of all terms linking any two given states A and B, those which contain more than the least possible number of steps ('roundabout transitions'). This leads to an equation (II) in which the amplitude of each state still appears as a function of time.

Alternatively, in the stationary theory, equations are used which define only the amplitudes of states of equal energy, and the results do not claim to be valid except in the limit of very long times.

Recently, Bethe and Oppenheimer[3] have shown that the omission of the roundabout transitions leads to trouble in the case of the scattering of charged particles by a centre of force. Their arguments have been criticized on the grounds that they neglect terms of higher order than the first in $e^2/\hbar c$, which amounts to neglecting the possibility of more than one photon being emitted. Actually, one knows that in infinite space the number of photons will show a logarithmic infinity (infra-red catastrophe).

We may, however, consider the scattering inside a finite box with conducting walls. In that case the probability of emission of two or more photons is negligible, provided (log $E/h\nu_{\text{min.}}$)/137 is a small number. Here E is the initial energy of the particle and $\nu_{\text{min.}}$ the frequency of the longest wave possible in the box. This limits the size of the box, but it need not be much smaller than the universe.

In that case the approximation used by Bethe and Oppenheimer is justified and, for a box of reasonable size, it gives then the result that the total collision cross-section contains a logarithmic term depending on $\nu_{\text{min.}}$, and hence on the size of the box. The variation of the cross-section due to that term may be of the order of one part in 10^6, and its observation, together with the knowledge that the particle is within the box, would, therefore, not violate the uncertainty relations.

Now the scattering can, in fact, be observed with sufficient accuracy in a time less than that needed for a light signal to reach the wall of the box, and, on physical grounds, it ought not to be influenced at all by the existence of the walls. One would, therefore, suspect that the radiation damping theory is not compatible with the description of the propagation of light with light velocity. In order to investigate this, we have studied directly the transmission of light from one atom to another in the damping theory.

Assume two identical atoms, P and Q, each of which has only two states, 1 and 2, differing in energy by $h\nu_0$. They are at a distance r from each other, such that $c/\nu_0 \ll r \ll c/\gamma$, where γ is the line width of the excited state, 2. These two inequalities are evidently well compatible. Initially P is excited (state 2) and Q in state 1, and no light quanta (at any rate of frequencies comparable to ν_0) are present. The lower limit of r ensures that the knowledge of the energy of the atoms specified by this description can be obtained in a time much less than r/c. We must then expect from a reasonable theory that the probability of Q being excited should remain zero for a time of about r/c and should then rise.

If, however, we apply the time-dependent damping theory, we have to consider as states of equal energy the initial state 0, the state A, in which Q instead of P is excited, and the state B, in which both atoms are in the ground state and there is a photon of frequency about ν_0. 'Intermediate states' are those in which there is a photon of frequency appreciably different from ν_0 and, since these states form a continuum, the assumptions made in deriving equation (I′) do not hold. We must choose our interval Δ of the order of the line-width, say, equal to $k\gamma$, where k is a number of order unity or less. In this case A and 0 are not coupled directly, but they are coupled through a state of equal energy as well as through 'intermediate states'. The procedure of damping theory is therefore ambiguous.

We may either regard the terms involving intermediate states as 'roundabout transitions' and omit them, or we may include them. If they are omitted, the time-dependent amplitude for state B will contain only Fourier components the frequency of which is the same within a range $k\gamma$, and since the number k must be independent of the problem to which the theory is applied, we can always make $k\gamma$ less than c/r. It is then impossible to obtain a function which remains zero for a duration r/c unless it is always zero. Indeed, calculation shows that the amplitude of state B is a power series in the time which begins with a quadratic term. Alternatively, if we had included intermediate states, equations (I′) and (II) would contain a direct coupling between states 0 and B and we would also find a finite probability of immediate excitation of atom Q.

In either case, the present form of the time-dependent radiation theory does not give a sensible answer to the propagation problem, and it cannot, therefore, be regarded as a satisfactory *general* procedure in radiation theory.

In the stationary theory, on the other hand, the problem of light propagation cannot be treated, since only asymptotic results are obtained from this theory. It may be, of course, that the procedure can be generalized so as to include non-stationary phenomena. If this is possible, without affecting the stationary case, we must find, after an infinite time, a cross-section depending on the size of the box. If the theory is to account for the propagation of light it must, however, after a finite time T, be independent of the linear dimensions of the box provided only they are greater than cT. It follows, then, that a correct generalization of the damping theory to time-dependent problems, which must differ from Heitler's equation (II), would have to lead to the result that the cross-section would depend on the time taken for the observation. We can see no rigorous argument against such a result, but it seems curious.

We are indebted to Dr. Hu for directing our attention to the difference between the two forms of the damping theory.

Radiation Pressure

THE methods given in most text-books for finding an expression for the pressure exerted by electromagnetic radiation on an obstacle generally depend upon a consideration of the lateral pressure of tubes of force, or some similar argument, and do not answer *directly* the question: What is the action of the electromagnetic field on the electrons in the absorbing (or reflecting) surface on which the pressure is actually observed? The following short method of finding the action of the field on an electron, and hence on a body, is therefore given here.

Suppose a train of plane electromagnetic waves is proceeding in the x-direction; let the electric and magnetic fields at a point A be in the y-direction and the z-direction respectively, and have components $(0,E_y,0)$ (in E.S.U.) and $(0,0,H_z)$ (in E.M.U.) respectively at a given moment. An electric charge at A will be set in motion in the y-direction by the action of the electric field, and will therefore experience a force in the x-direction owing to the action of the magnetic field. If the velocity components of the motion are $(0,v,0)$, then the force in the x-direction will be

$$P_x = H_z ev/c,$$

where c is the velocity of light in free space. If the charge is quite free to move and radiates no energy, the velocity v will lag behind the sinusoidally varying field E_y by a quarter of a cycle. It will also lag behind the magnetic field by a quarter of a cycle, and thus the mean value of $H_z v$, and therefore of P_x, will be zero.

If the charge does not move freely, then it will take energy from the electromagnetic field. The field does work on the charge at a rate

$$\frac{dW}{dt} = E_y ev,$$

and the charge, therefore, takes energy from the field at this rate. But since $H_z = E_y$ for a progressive wave in free space, it follows that

$$P_x = \frac{H_z ev}{c} = \frac{E_y ev}{c} = \frac{1}{c}\cdot\frac{dW}{dt}.$$

This shows that when an electric charge absorbs energy at a rate dW/dt from a train of electromagnetic waves, it experiences a force, $\frac{1}{c}\cdot\frac{dW}{dt}$, in the direction of the wave-motion. An equivalent statement is: when an electric charge receives an amount of energy W from a train of electromagnetic waves, it receives also momentum W/c in the direction of the wave-motion.

Thus if radiation with energy density ε per unit volume falls on a surface which absorbs it completely, the total rate of absorption of energy by the electrons in the absorber must be $c\varepsilon$ per unit area of absorber, and the absorber must therefore experience a pressure $\frac{1}{c}\cdot c\varepsilon = \varepsilon$. In the case in which all or part of the radiation is reflected, we can apply similar arguments to show that the reflected radiation exerts an additional pressure on the reflector.

Paramagnetic Resonance and Magnetic Energy Levels in Chrome Alum

Zavoisky[1] and also Cummerow and Halliday[2] have shown that a resonance absorption of high-frequency waves occurs in some paramagnetic salts in a magnetic field of appropriate value. This is due to induced transitions between two of the energy levels of the paramagnetic ion, the energy of which depends on the magnetic field. In the simplest case where the magnetic moment is due to spin only, the difference of energy is given by $2\mu_0 H$, where μ_0 is the Bohr magneton and H the magnetic field. The resonance condition is then $2\mu_0 H = h\nu$. The results obtained so far have shown a single resonance absorption with a peak very near the value given by the above relation.

We have investigated the absorption in a single crystal of chrome alum at wave-lengths between 3 and 10 cm. In this case, several absorption peaks appear, and typical curves of absorption against magnetic field at a fixed wave-length are shown in Fig. 1. The curves 1, 2 and 3 were obtained at a wave-length of 3·18 cm. and with the magnetic field directed along the normals to the 100, 110 and 111 planes of the crystal respectively. The crystal was placed in an H_1 resonator arranged so that the oscillating magnetic field was at right-angles to the steady field. The ordinates in Fig. 1 are proportional to the absorption in the salt (the scale is different for the three curves) and are obtained by measuring the decrease in Q (circuit magnification) of the resonator at different values of the magnetic field.

A theoretical treatment of the lowest energy-levels of the Cr^{+++} ion in chrome alum under the combined influence of the crystalline electric field and of an external magnetic field has been given by Broer[3]. In this treatment it is assumed that the crystalline electric field is mainly of cubic symmetry, but that there is also a small component with trigonal symmetry, the trigonal axis being one of the space diagonals of the unit cell. The lowest energy-levels are

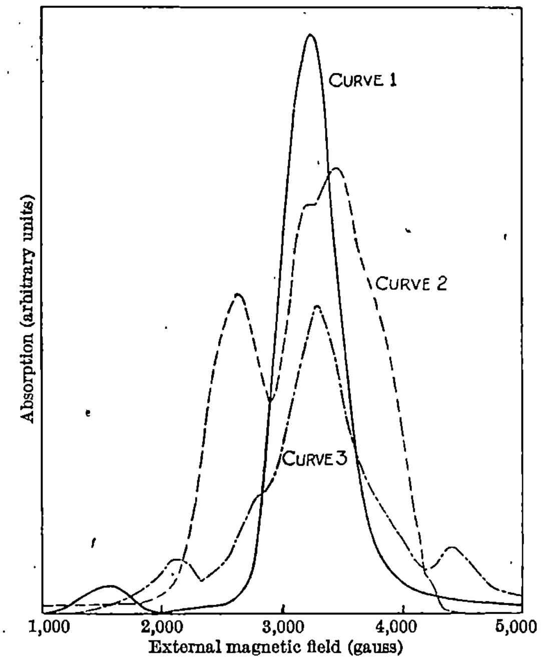

Fig. 1

then found to be two degenerate levels of spin ± 1/2 and ± 3/2 separated by a small interval of energy a.

Fig. 2 shows how the energy of the four levels varies with magnetic field. Two cases are shown for different directions of the magnetic field corresponding to cos $\theta = 1$ (full lines) and cos $\theta = 1/3$ (broken lines), where θ is the angle between the trigonal axis and the magnetic field. The ordinates in Fig. 2 are expressed in terms of the energy interval a. Experimentally the frequency is kept constant and the magnetic field varied, and it will be seen that there are several values of the magnetic field at which transitions of given energy should be found, and that these will depend on the orientation of the crystal in the magnetic field.

As an example, the case where the magnetic field is directed along a space diagonal of the unit cell may be considered. Here cos $\theta = 1$ for one out of four Cr ions and cos $\theta = 1/3$ for the others. The experimental results obtained at $\lambda = 3 \cdot 18$ cm. are shown as curve 3 in Fig. 1, and similar curves were obtained at other wave-lengths up to 10 cm. From these curves may be plotted the values of H at which peaks of absorption occur, against $1/\lambda$, and these are shown as the experimental points in Fig. 3. Also plotted in Fig. 3 are the theoretical curves of H against $1/\lambda$ for various transitions which can occur. The full lines are for cos $\theta = 1$ and the broken lines for cos $\theta = 1/3$. Only the three well-defined peaks in curve 3 have been plotted in Fig. 3. Other absorption lines should occur on each side of the main peak, and there are clear indications of these in the experimental curves. Again, in curve 1 of Fig. 1 the main transitions should give two lines close together, but these are not resolved and appear as a single large peak of absorption. Thus there is general agreement between the experimental results and the theoretical description; but owing to the considerable width of the absorption lines it is difficult to verify the theory in great detail.

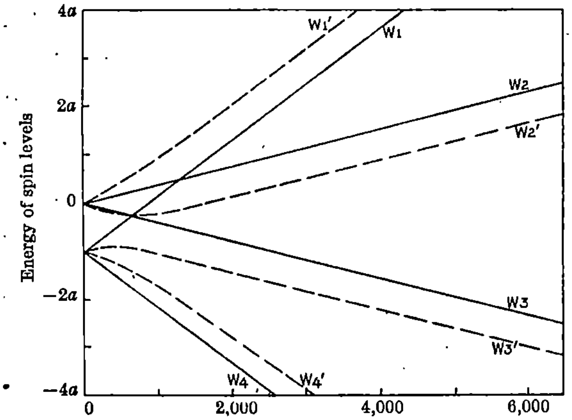

Fig. 2

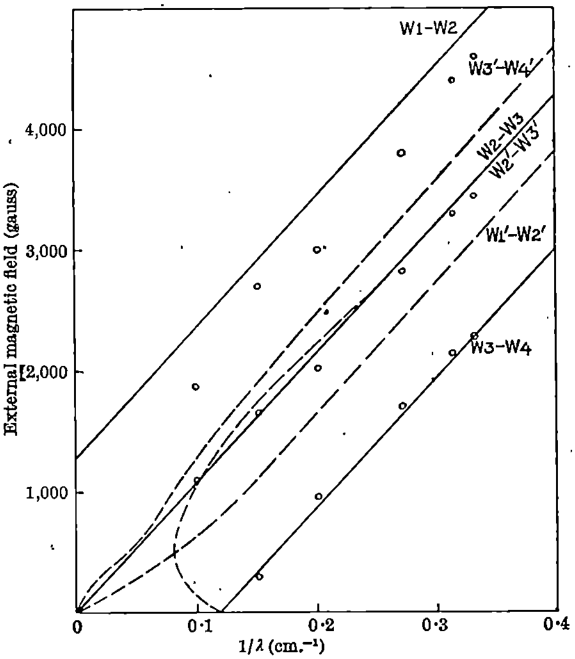

Fig. 3

From these measurements it appears that the best value of a, the 'splitting' of the energy-levels at zero magnetic field, is $0 \cdot 12$ cm.$^{-1}$, and this value has been used in the theoretical calculations. This compares with the value of $0 \cdot 17$ cm.$^{-1}$ found from low-temperature measurements. The difference may be due to a change in the crystalline electric field with temperature.

Thus it appears that, in suitable cases, this method of investigation may be capable of giving detailed information of the lowest energy-levels of a paramagnetic ion in a salt, and therefore of the crystalline electric field acting on that ion.

A full account of these measurements and also of measurements on other salts will be published in due course.

Photo-Disintegration of the Deuteron

THE theory of the photo-disintegration of the deuteron[1] indicates that the process should be predominantly due to photo-electric transitions for γ-ray energies considerably greater than the threshold energy (2·18 MeV.). The angular distribution of the protons emitted in such transitions should be represented by the function

$$f(\theta)d\theta = k\sin^2\theta d\theta,$$

where θ is the angle between the direction of the emitted proton and that of the incident γ-ray, and $f(\theta)$ is the number of protons emitted per unit solid angle at the angle θ.

At high γ-ray energies, according to more recent calculations based on meson theories of nuclear interaction[2], the angular distribution of the emitted protons should show deviations from this distribution, particularly in an increase of the ratio of the number of protons emitted at small angles to the number emitted in directions perpendicular to that of the γ-ray beam. Accurate determinations of the angular distribution at high energies should therefore yield information concerning the validity of various theories of the short-range forces between the neutron and the proton.

It is the purpose of this note to describe some preliminary results obtained in the course of an investigation of the photo-disintegration process by the photographic plate method. A proton beam of 80 microamp., accelerated through 950 kV. by the Cavendish Laboratory high tension equipment, was used to bombard a thick target of sodium fluoride. The 6 MeV. γ-rays produced in the bombardment of fluorine by protons[3] were incident upon a series of photographic plates, the emulsions of which contained a proportion of deuterium. The plates were of the Ilford Nuclear Research *C*2 type, with 100 micron coating, and they were specially prepared with a loading of calcium nitrate containing heavy water of crystallization. The proportion of heavy water in the emulsion was approximately 6 per cent by weight. The plates were exposed for five hours at a distance of 5 cm. from the fluoride target, and they were processed in the usual manner. A microscope examination showed that proton tracks occurred in the plates and that the γ-ray fogging was not excessive.

The exposed plates were examined under a high-power microscope, and an area of 230 sq. mm. was covered in this investigation. The observers recorded all proton tracks with a range greater than 20 microns which were entirely contained in the emulsions. The direction of each proton recorded was ascertained by observation of the variation of the grain density along the track. Fig. 1 shows the distribution in range of 29 tracks occurring in the angular range $70^\circ \leqslant \theta \leqslant 110^\circ$. The tracks represented in this diagram had an angle of dip of less than 10° in the emulsion; this criterion was adopted because the accuracy of range measurements decreases with increasing angle of dip. Fig. 1 shows that a proton group occurs with a mean range of 36 microns, corresponding to a proton energy of 1·88 MeV. This is clearly due to the photo-disintegration process, since the calculated γ-ray energy is $(6 \cdot 0 \pm 0 \cdot 2)$ MeV., in agreement with the known energy of γ-rays emitted in the F + *p* reaction. At angles greater than 110°, proton tracks were less abundant, but the photo-disintegration group was still resolved, and the mean range decreased with increasing angle in the correct relation. At angles less than 70°, a larger number of proton tracks was found, and the correlation of range with angle showed clearly that some of these were caused by protons scattered by a background of neutrons which arose from the contamination of the accelerating tube with deuterium. These neutrons were probably responsible also for the small number of proton tracks occurring outside the main group in Fig. 1. At angles less than 70°, the protons produced by photo-disintegration were not clearly resolved from those scattered by neutrons.

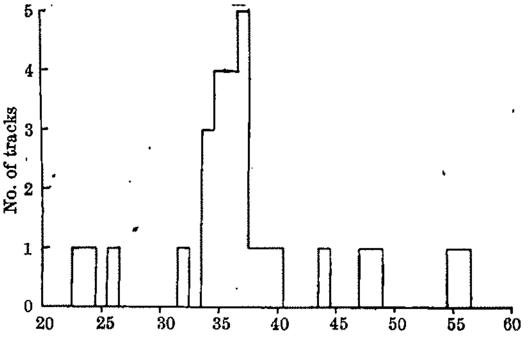

Fig. 1. RANGE DISTRIBUTION OF PROTON TRACKS IN ANGULAR RANGE $70^\circ \leqslant \theta \leqslant 110^\circ$

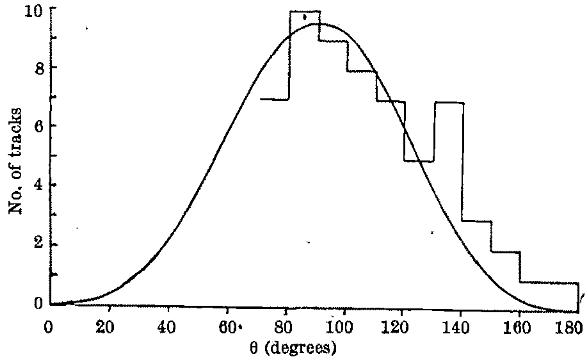

Fig. 2. ANGULAR DISTRIBUTION OF PROTON TRACKS PRODUCED IN PHOTO-DISINTEGRATION OF DEUTERIUM

The total number of proton tracks recorded was 213, and, of these, 60 occurring in the angular range $70^\circ \leqslant \theta \leqslant 180^\circ$ were ascribed to the photo-disintegration process. This abundance is in approximate agreement with that calculated from the known γ-ray strength of the source and the cross-section determined by Van Allen and Smith[4]. The angular distribution of the photo-disintegration protons is shown in histogram form in Fig. 2. The continuous curve is the theoretical curve, calculated from the $f(\theta)$ distribution with a small correction for escape of protons from the emulsion and adjusted to fit the experimental results at $\theta = 90^\circ$. The agreement between theoretical and experimental distributions is fairly close and the discrepancies at very high angles are probably due to the lack of accurate geometrical conditions in the irradiation of the plates.

This method of investigating the photo-disintegration of the deuteron and of measuring γ-ray energies is capable of several improvements, particularly in the introduction of a higher proportion of deuterium into the emulsions, and of extension to higher γ-ray energies. We are indebted to Mr. C. Waller and the research staff of Ilford, Ltd., for their work in preparing the plates, and to Dr. W. E. Burcham for much helpful advice.

Mechanism of Ferromagnetic Dispersion

Further experiments have been made to elucidate the mechanism responsible for the magnetic dispersion and absorption of γ-ferric oxide at centimetre wave-lengths, previously reported[1]. Using the wave-guide impedance method[2,3], the high-frequency permeability $\mu = \mu_R - i\mu_I$ of γ-Fe_2O_3-wax mixtures has been measured in a coaxial transmission line, when a static magnetic field H is applied perpendicular to the axis. Typical results obtained on specimens containing 32·6 per cent by volume of γ-Fe_2O_3 are plotted in Fig. 1, together with measurements of the incremental static permeability, μ_0.

Various theories of ferromagnetic dispersion have been proposed. Skin effect, suggested by Page[4] and Kittel[5] as the dispersion mechanism for powders and metals respectively, is negligible in γ-Fe_2O_3 at centimetre wave-lengths[3]. Becker[6] has developed a theory of dispersion, due to eddy-current fields produced by oscillatory displacements of the domain-walls. Irreversible displacements, corresponding to the peak in the $\mu_0 - H$ curve, should disappear at low frequencies, and the present results substantiate this.

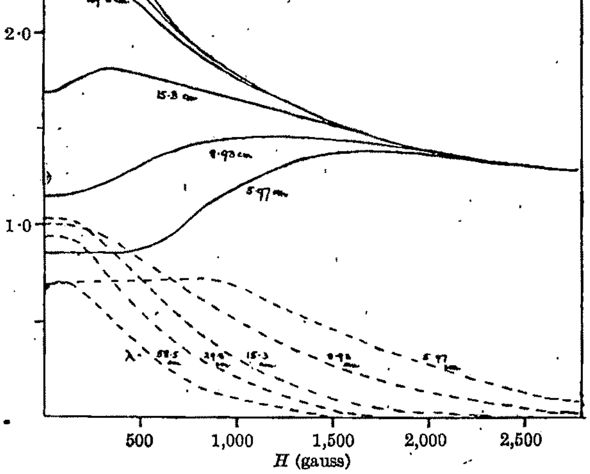

Fig. 1

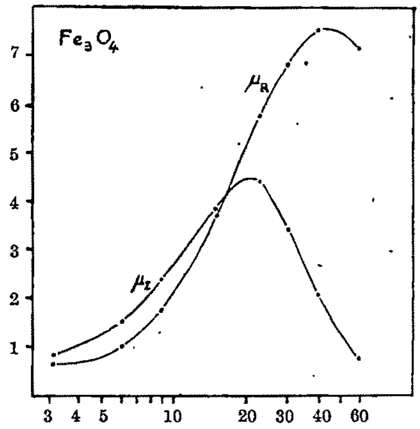

Fig. 2

It does not appear, however, that the micro-wave dispersion is attributable to Becker's other mechanism, the relaxation of reversible displacements. The insensitivity of μ to applied fields of a few hundred gauss indicates the action of a strong- and not a weak-field effect, while the experimental $\mu - \lambda$ curves have the characteristics of a damped resonance and not a relaxation.

It appears rather that the primary mechanism in the high-frequency magnetization is domain-spin rotation. For large H, μ is real and equal to μ_0, but as either λ or H is decreased, μ_R falls below μ_0 while μ_I increases, indicating a phase lag of the spin-rotation behind the high-frequency field. Landau and Lifshitz[7] have developed a theory of dispersion due to spin-rotation, and they predict a resonance occurring when the applied frequency is equal to the spin precession frequency in the internal crystalline field. Allowing for their neglect of eddy-current damping, the observed dispersion is in good agreement with this theory. The peak which might be expected in the $\mu_R - \lambda$ curve lies outside the measured wave-length range for γ-Fe_2O_3, but such a peak has been observed in measurements on Fe_3O_4, plotted in Fig. 2.

Location of the Currents Causing the Solar and Lunar Diurnal Magnetic Variations

In 1882 Balfour Stewart[1] put forward the view that the solar and lunar diurnal magnetic variations were produced by currents in the upper atmosphere. He suggested that these currents were produced by the 'dynamo' action of thermal or tidal motions of conducting air across the earth's main magnetic field. Schuster[2] put these suggestions on a quantitative basis. It was later realized (Chapman[3]) that there were difficulties in assigning both the solar and lunar variations to a single ionized region. For example, the amplitude of the former is some 2·4 times larger in summer than winter, whereas the corresponding ratio for the latter is 4. Again, solar variations are some 1·6 times greater at sunspot maximum than at sunspot minimum, but lunar variations show little difference in amplitude between sunspot maximum and minimum. Since it is unlikely that the tidal motions change so markedly with season and sunspot activity, it seems probable that the conductivities of the regions responsible for the variations change in the above ratios: and since these ratios are different for solar and lunar variations it would seem that these variations must arise in different conducting regions of the atmosphere.

Appleton's discovery of the existence of more than one ionized region in the upper atmosphere appeared likely at first to lead to an early solution of this difficulty. In particular, the identification by Fleming[4] and McNish[5] of temporary augmentation of solar variation with temporary increase in D-region ionization suggests strongly that a main part of the solar variation is produced in and near this region. This leaves the lunar variation to be assigned to one of the other regions of the ionosphere. Unfortunately, none of these other regions exhibits seasonal and sunspot changes in conductivity which agree even roughly with those shown by the lunar variations. In general, all the known regions show too great a sunspot variation and too little seasonal variation for such identification. It is unlikely, from consideration of the conductivities at various pressures (in the presence of the earth's permanent magnetic field), that the lunar variations could be produced below the D-region, or above the F_2-region. Hence we are faced with the dilemma that the lunar variations cannot apparently be produced in any of the known, or even in any of the possible unknown, ionized regions of the upper atmosphere.

A way out of this difficulty appears to emerge from the results of a statistical study of tidal movements in the ionosphere, which has been proceeding for the past two years. One object of this analysis has been to test the concept that tidal height changes in ionospheric levels, such as were discovered by Appleton and Weekes[6], are not due directly to atmospheric tidal pressure changes, but are a by-product of the resulting 'dynamo' currents. Thus, at the pressures existing in the ionosphere, ions and electrons must drift vertically whenever a horizontal electric force acts across the horizontal component of the earth's field. The pattern of ionosphere currents which is necessary to explain the magnetic variations is well known. It consists of large roughly circular whorls in each hemisphere, with foci near lat. 40°. A crucial test of the above concept is then to determine the phases of the tidal movements of a given region of the ionosphere at latitudes on the poleward and on the equatorial sides respectively of these foci. If the concept be correct, there should be a reversal of phase on crossing the foci; while on the simple tidal hypothesis the phase should be approximately constant at all latitudes. Appleton and Weekes found that the E-region in south-east England reached its maximum height 11·2 hr. after lunar transit. A corresponding study of four years hourly data at Canberra (lat. 35·3° S.) shows that the E-region at this latitude attains maximum height 5·1 hr. after lunar transit. Almost identical results have been obtained for other Australian stations at lower latitudes. It seems, therefore, that the E-region height variations at low latitudes (less than 40°) are almost exactly out of phase with those in England, and we should be on safe ground in interpreting the sense of height movements in the ionosphere in terms of the directions of the electric currents there.

On this basis the results of the statistical analysis of the lunar height variations in the E-, F_1- and F_2-regions at a number of ionospheric observatories have been examined. It has been found that the currents in each of these regions are almost exactly out of phase with those required to produce the lunar variations. It follows from what has been said above that the main seat of the lunar variations, like that of the solar variations, probably lies in the D-region.

At first sight this surprising conclusion only seems to increase the initial difficulty of explaining the different seasonal and sunspot variations of the solar and lunar variations. Further study of the *solar* tidal movements in the E-, F_1- and F_2-regions of the ionosphere has brought to light a circumstance, however, which appears to provide a logical explanation of their different behaviour. This statistical study of the solar ionospheric tidal movements shows that the solar currents in the E-, F_1- and F_2-regions are substantially in phase with those which must be presumed to flow in the D-region, on McNish's evidence. On the basis of these analyses we may represent the solar variations (S) and the lunar variations (L) thus:

$$S = S_D + S_{EF} \quad . \quad . \quad . \quad . \quad (1)$$

$$L = L_D - L_{EF} \quad . \quad . \quad . \quad . \quad (2)$$

If now L_{EF} is not much smaller than L_D (say, 12 per cent less) the observed peculiarities of the lunar variation fit into place. The lunar variations may be aptly compared to a temperature-compensated pendulum, the D- and EF-regions having slightly different coefficients of expansion. For the sunspot variation of L to be negligible the electrical conductivity of the EF-region must be slightly more variable with sunspot activity than that of the D-region, the coefficients expressing this variation being in the ratio 1·62/1·55 or 1·045. (These figures are in keeping with the known general trend of this coefficient in the ionosphere, Allen[7] finding the ratio 1·045 for the F_1- to E-region coefficients.) For the case of the seasonal variation, ratios of summer/winter conductivity of 2·6 and 2·3 for the D- and EF-regions respectively are required to explain the observed large seasonal variation in the lunar variation. (In this case the analogy with the temperature-compensated pendulum may be preserved by supposing that the two metals have been reversed, thus exaggerating instead of suppressing the variations in length of the pendulum.)

One other notable feature of the lunar variation seems more readily understandable if the above conclusions be accepted. It is known that it increases markedly with increasing magnetic disturbance, but that the rate of increase is greatest when the disturbance activity is small. It is also known that the D-region conductivity increases with magnetic activity, but that there is little effect (possibly even a small decrease) in EF-conductivity. From equation (2) it is readily seen that a given fractional increase in L_D produces a much larger fractional increase in lunar variation when L_D is comparable with L_{EF}. On the other hand, when L_D becomes larger, this magnification falls off rapidly, in keeping with the known behaviour of the lunar variations with increasing disturbance.

This work, which will be published in full elsewhere, is being carried out as part of the research programme of the Radio Research Board of the Council for Scientific and Industrial Research.

Prof. S. Chapman, through whom Dr. D. F. Martyn has forwarded this letter, remarks that equations (1) and (2) imply horizontal inducing motions due to the sun, in the *D*-, *E*- and *F*-layers, which are in phase with one another, and *lunar* tidal horizontal motions which in the *D*-layer are opposite in phase to those in the *E*- and *F*-layers; on present knowledge (cf. *Nature*, **159**, 357; 1947), this does not seem to be excluded.

Mechanism of the Oxidation of Gaseous Formaldehyde

THE oxidation of gaseous formaldehyde has been studied by Askey[1], Fort and Hinshelwood[2], Bone and Gardner[3], Spence[4], and Snowden and Style[5]. Spence[4] was the first to investigate the reaction comprehensively and to propose a mechanism. Snowden and Style[5] also proposed a somewhat similar but incomplete mechanism. Neither is able to account for a further important observation that has now emerged—first mentioned by Style and Summers[6] and now confirmed by our results—that, concurrently with the oxidation of the formaldehyde, there is a sensitized decomposition to carbon monoxide and hydrogen, linked with it. This decomposition does not take place in the absence of oxygen, and at very low partial pressures of oxygen assumes a relatively predominant role.

It appeared to us that, since formaldehyde may be formally represented as a mixture of hydrogen and carbon monoxide and readily decomposes to these gases, and since its ignition temperature at pressures below atmospheric is of the same order as that for hydrogen–carbon monoxide/oxygen mixtures[7], the mechanism of the homogeneous reaction might well be represented by an adaptation of the schemes employed in the oxidation of hydrogen and hydrogen–carbon monoxide mixtures[8,9]; and on the basis of the previous work and additional results shortly to be published[10] we have been able to show that the oxidation can be described by a mechanism involving hydrogen atoms along the same lines as the hydrogen/oxygen reaction.

Consideration of related reactions, namely, the photolysis and photo-oxidation of formaldehyde, suggests that the reactions

$$\begin{aligned} \mathrm{H} + \mathrm{HCHO} &= \mathrm{H_2} + \mathrm{CHO} \\ \text{and}\quad \mathrm{O} + \mathrm{HCHO} &= \mathrm{OH} + \mathrm{CHO} \end{aligned}$$

may well be involved in the thermal reaction. Since the formyl radical which is precariously stable at 100° C. is almost certainly unstable at the temperatures used for the oxidation (300–340° C.), these equations may be written:

$$\begin{aligned} \mathrm{H} + \mathrm{HCHO} &= \mathrm{H_2} + \mathrm{CO} + \mathrm{H} \\ \text{and}\quad \mathrm{O} + \mathrm{HCHO} &= \mathrm{OH} + \mathrm{CO} + \mathrm{H}, \end{aligned}$$

and a chain reaction scheme involving H, OH and HO_2 can be set up which leads to an expression for the rate which can account for the kinetic results very satisfactorily. The full scheme is as follows:

$$\begin{array}{lll} (1)\ \mathrm{O_2+HCHO=H_2CO_2+O} & k_1 & \multirow{2}{*}{\Big\}\ \text{initiation}} \\ (2)\ \mathrm{O+HCHO=OH+H+CO} & k_2 & \\ (3)\ \dot{\mathrm{H}}\mathrm{+HCHO=H_2+CO+H} & k_3 & \Big\}\ \text{propagation-decomposition} \\ (4)\ \mathrm{OH+HCHO=H_2O+CO+H} & k_4 & \\ (5)\ \mathrm{H+O_2+HCHO=H_2O+CO+OH} & k_5 & \Big\}\ \text{propagation oxidation} \\ (6)\ \mathrm{H+O_2+HCHO=H_2O+CO_2+H} & k_6 & \\ (7)\ \mathrm{H+O_2+O_2=HO_2+O_2} & k_7 & \\ (8)\ \mathrm{H+O_2+}X\mathrm{=HO_2+}X & k_8 & \Big\}\ \text{termination} \\ (9)\ \mathrm{H+O_2+wall=HO_2} & k_9 & \end{array}$$

$$\mathrm{HO_2} + \text{wall} \rightarrow \text{decomposition}.$$

Bowen and Tietz[11] have shown that at low temperatures formaldehyde readily reacts with oxygen to give performic acid, and for the initiation reaction (1) we assume that, at the temperatures involved (c. 350° C.) here, this peracid is not formed but that the normal acid and an oxygen atom are produced instead. Reactions (7), (8) and (9) allow for the fact that the HO_2 radical can only be stabilized in a three-body collision. There is no evidence to indicate that the oxidation involved branched chains at the temperatures at which it has been studied, but the fact that ignition eventually occurs at temperatures in the region of 500° C. can readily be interpreted on the above scheme if the branching reaction $H + O_2 = OH + O$ becomes important at this temperature, a fact already known from the kinetics of the hydrogen/oxygen reaction.

The net overall effects of this chain mechanism are the three complex homogeneous reactions:

$$\begin{aligned} \mathrm{H_2CO} + \mathrm{O_2} &= \mathrm{H_2O} + \mathrm{CO_2} \\ \mathrm{H_2CO} + \tfrac{1}{2}\mathrm{O_2} &= \mathrm{H_2O} + \mathrm{CO} \\ \mathrm{H_2CO} &= \mathrm{H_2} + \mathrm{CO} \end{aligned}$$

in accordance with our experimental results. Of these the second predominates except at very low oxygen concentrations, when the sensitized decomposition reaction becomes relatively more important.

The above scheme leads to the following expression (1) for the disappearance of formaldehyde, $[F]$ referring to the formaldehyde concentration, and S/d being the ratio of surface to volume (S = constant and d = diameter of reaction vessel):

$$-\frac{dF}{dt} = \frac{k_1(2k_5 + k_6)[\mathrm{O_2}]\,[F]^2}{k_7[\mathrm{O_2}] + k_8[X] + k_9[S]/d} + \frac{k_1 k_3 [F]^2}{k_7[\mathrm{O_2}] + k_8[X] + k_9[S]/d} \qquad (1)$$

the first term representing oxidation and the second decomposition. In the absence of inert gas, and in vessels of large diameter with concentrations of oxygen that are not small compared with $[F]$, this expression reduces to an expression for the initial rate as follows:

$$-\frac{dF}{dt} = \frac{k_1(2k_5 + k_6)\,[F]^2}{k_7} \qquad (2)$$

in agreement with previous workers' results; as the products of reaction accumulate the term $k_8[X]$ modifies the later course of the reaction. In vessels of very small diameter, or in packed vessels where S/d is large, the homogeneous reaction is very slow, and this also follows from equation (1). Aside from the fact that they do not account for the sensitized decomposition, the previous schemes in our view are unsatisfactory in that they suggest no initiation reaction and involve a disproportionate number of *ad hoc* assumptions: we believe that the mechanism given above is capable of describing the observed phenomena of this puzzling reaction, and it has the advantage of being in harmony with the analogous reactions of the oxidation of hydrogen and hydrogen–carbon monoxide mixtures, involving practically no additional assumption.

Some Fatigue Effects on the Human Retina Produced by Using Coloured Lights

When Burch (1898 and 1900) fatigued the human eye by exposure to sunlight through a suitable colour filter, he found evidence for four sensations: red, green, blue and violet, but not for yellow. Edridge-Green and Marshall (1909), after exposing the eye to sodium light, stated that they found definite evidence for a separate yellow sensation. I have recently repeated these experiments, with certain modifications which will be described, and I have arrived at the same conclusion as Edridge-Green and Marshall.

A colour filter was prepared, using gelatin films dyed with Naphthol Green, Malachite Green, Orange G and Naphthol Yellow, which transmitted a narrow lemon-yellow band centred on 0·57 μ. This filter was placed in front of a small lantern condenser behind which was mounted a 36-watt tungsten filament lamp. The observer's eye was carefully adjusted in position until the image of the lamp filament coincided with the pupil, so that a nearly uniform yellow area, subtending about 20 degrees of arc, was presented to his retina. The placing of a disk of ground glass next to the lamp bulb, and the use of a condenser consisting of achromatic lenses, was found to improve the uniformity of the field. (This was particularly useful in the case of the dichromatic filter, which will be referred to shortly.) The use of a dental impression plate for steadying the head is indicated in cases where the observer finds it difficult to preserve the correct eye position.

It was no advantage for the yellow light to be excessively bright; 200–400 ft. c. appeared to be most suitable. If after 15–20 seconds observation it is found to take on a pale lilac tint it is probably too bright and should be reduced. The eye having been exposed to this yellow light for $\frac{1}{2}$–1 minute, a spectrum was examined with as little delay as possible. A simple hand spectroscope was found to be suitable for this purpose. This spectrum should not be too bright; one in which the yellow region has a brightness of 10–20 ft. c. seems to be most suitable.

After exposure to yellow light, as described above, the spectrum was found to be darker than usual in the blue and violet; the red region had a purplish-pink colour, the green appeared pale blue-green, and lying between them was a narrow neutral tint area completely devoid of any yellow colour. On continuing to watch the spectrum the yellow slowly reappears, the red and green gradually lose their bluish hue, the blue and violet recover their usual intensity, but it is some minutes before the normal appearance of the spectrum is reached. Some idea of the extent of these changes after exposure to yellow light, and of the rate of recovery from it, may be obtained by repeatedly comparing the spectrum seen by the exposed eye with that seen by the normal eye.

The tests with the spectroscope were now repeated using a second colour filter, giving a light which closely resembled in brightness and colour, but which was slightly less saturated than, that used in the tests described above; but, instead of transmitting a monochromatic yellow, it transmitted a band in the red, centring on 0·69 μ, and a band in the green, centring on 0·53 μ. On repeating the tests, using this filter, it was found that changes in the appearances of the different parts of the spectrum were much smaller than those just described. Thus yellow was not so saturated in colour, but was not replaced by grey; red and green were less bluish, and the short wave-length end of the spectrum was scarcely altered. In one experiment one eye was exposed to the light from one filter, the other being at the same time exposed to the light from the other filter. On comparing the spectra it was clearly seen how very different they were. Thus these two yellow lights, which resemble one another closely to the eye, produce effects of quite different magnitude on colour vision.

Some further tests were now performed in which colour filters were used, each one transmitting a different narrow spectral band which varied in mean wave-length from 0·69 μ to 0·49 μ. When these were tested in turn for their effects on the spectrum, it was found that the most effective in altering yellow to grey were those which had transmission bands in the yellow and yellow-green. Next came those in the orange and the green; while those with bands at 0·69 μ, and at 0·51 μ and 0·49 μ, had no observable effect on the spectrum colours.

Instead of a spectrum some test colours may be examined, when it will be found after exposing the eye to pure yellow light that red looks crimson, orange looks red, yellow looks grey, green looks pale blue-green, and blue and violet look very dark blue-green.

These experiments confirm the observations of Edridge-Green and Marshall that exposure to monochromatic yellow light causes the eye for a time to see spectral yellow as neutral grey. They show, moreover, that a dichromatic yellow light, consisting of a band in the red and a band in the green, produces results on colour vision which are different from those produced by a monochromatic yellow light which has been adjusted to match it as closely as possible.

Some further tests were now performed. A yellow filter transmitting nearly the entire spectrum, except for the violet and part of the blue, was adjusted to match the monochromatic and dichromatic filters as closely as possible. Exposure of the eye to light which had passed through this filter was found to darken the whole spectrum, but otherwise to have no specific effect on it. A filter transmitting a narrow band at 57 μ and also a band in the greenish-blue from about 50 μ to 45 μ produced no specific effects either. On the other hand, a yellow filter transmitting from about 65 μ to about 55 μ was found to change yellow to grey, and in other ways to produce similar changes to those produced by the monochromatic yellow filter.

The conclusion arrived at is that, while fatiguing the eye to rays from about 65 μ to 55 μ causes changes in the red, the yellow and the green parts of the spectrum, fatiguing the eyes simultaneously to these rays and to greenish-blue rays, produces little or no effect; that is, the latter rays appear to inhibit the onset of the fatigue effects which rays from 65 μ to 55 μ would otherwise produce. The precise spectral limits and other details concerning these inhibitory rays have not yet been determined.

Experimental Production of a Protostele from a Dictyostele in *Dryopteris aristata*

In leptosporangiate ferns the incipient vascular tissue can be observed as an uninterrupted layer situated immediately below the apical meristem from which it is derived and enclosing a central pith. In this cone of incipient vascular tissue no leaf-gaps are present. The apical meristem can be isolated from the adjacent lateral organs (leaf primordia and scales) and tissues by vertical incisions[1,2]. This operation involves the severance of the incipient vascular tissue, the isolated meristem being now seated on a thin layer of incipient vascular tissue and the latter on a plug of pith parenchyma.

The isolated meristem continues to grow and forms a short shoot on which new leaf primordia later develop. In the lower region of this shoot, above the non-vasculated pith region, the stele is typically solenostelic. This result was predictable from a knowledge of the disposition of the tissue systems at the shoot apex. Since the amount of radial growth at the centre of the shoot is very small it could be further predicted that if the vertical incisions could be made sufficiently close to the apical cell the resulting thin shoot would be protostelic.

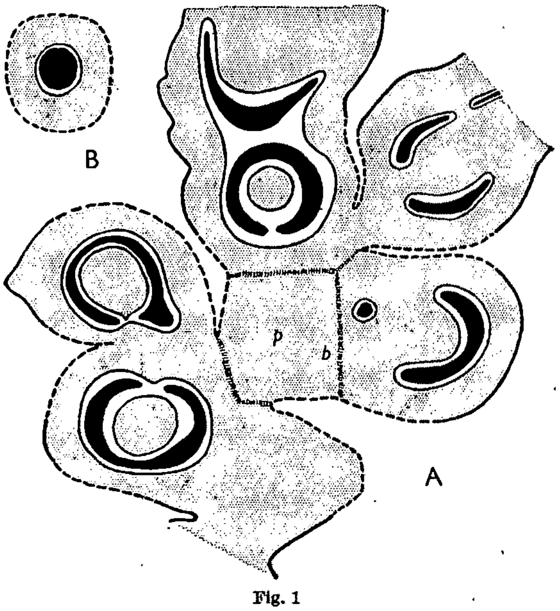

Fig. 1

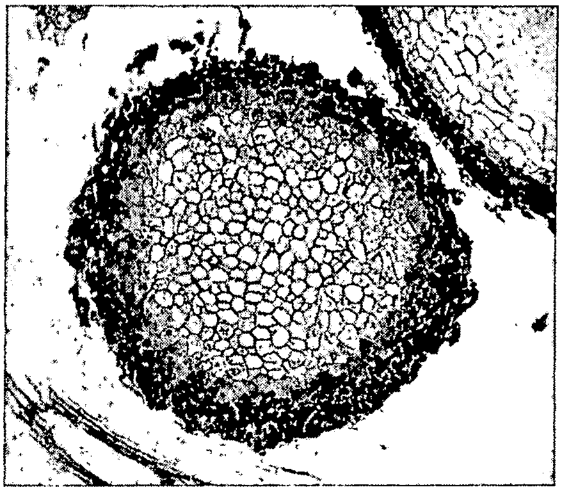

Fig. 2

In practice, this operation is difficult to carry out as the whole meristematic system tends to collapse and become necrotic. However, in the course of these experimental studies, some very small terminal shoots have been obtained, and in one of these the protostelic condition has actually been realized. Fig. 1 *A* shows a cross-section of an incised shoot of *D. aristata* near the base of the incisions (*b*), in the pith (*p*); the outer region of this shoot is almost completely occupied by the bases of the large solenostelic lateral buds which have developed as a result of the experimental treatment[2]. Fig. 1 *B*, taken higher up, shows a cross-section of the small protostelic shoot which has developed from the isolated apical meristem (xylem, black). Near the base of this shoot the stele is a small solenostele; higher up it becomes a medullated protostele (Fig. 4), and still higher up a solid protostele with a central core of xylem (Fig. 3). This shoot became attenuated and later stopped

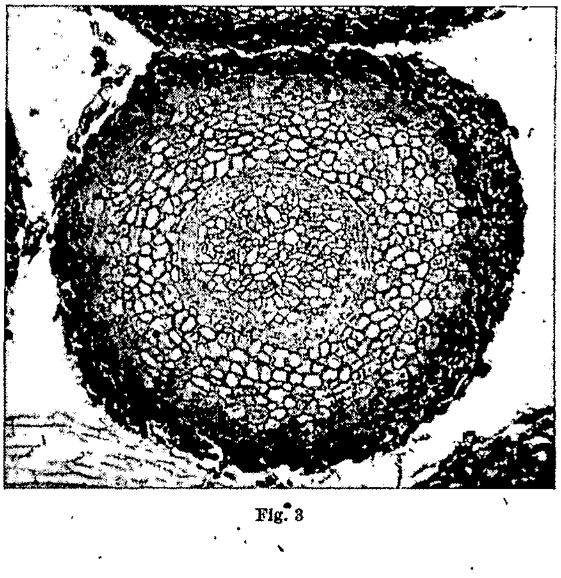

Fig. 3

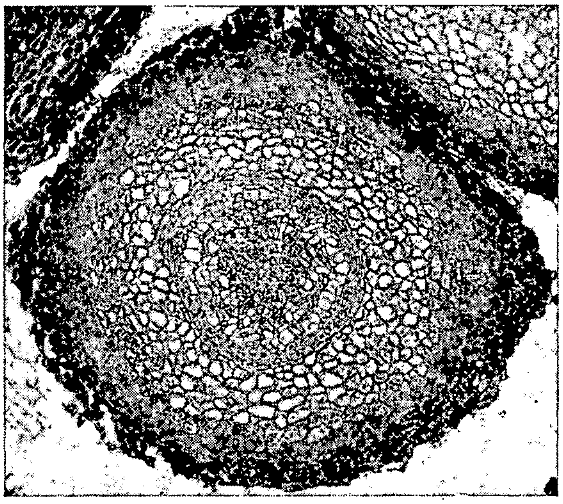

Fig. 4

growing; the meristematic character of the apex was lost and the distal region of the shoot became parenchymatous. Sections taken progressively nearer the distal region showed a decrease in the cross-sectional area of the protostele until eventually it faded out, the whole cross-section of the shoot being occupied by parenchyma, Fig. 2.

Carotenoid Pigmentation of Trout

TROUT kept in aquaria and fed on a diet of chopped meat and earthworms lose the brilliant yellow and red pigmentation characteristic of wild fish, but do not appear to suffer any other inconvenience. The xanthophore and erythrophore cells of the dermis become few in number and those remaining contain little pigment. As reported in a separate communication[1], the pigments specifically concerned in these changes are esters of the carotenoids lutein and astaxanthin. The melanophores are not affected. I find that the total carotenoid content of the skin and fins of depigmented fish is about a tenth that of the wild type (see accompanying table). Moreover, all the pigment remaining in the former is lutein, whereas in the latter lutein and astaxanthin (estimated as astacene) are present in much the same concentration. Trout reared from eggs in this laboratory in a balanced tank and fed solely on 'natural' foods consisting of such organisms as they could capture, supplemented from time to time by quantities of live Entomostraca, chiefly *Simocephalus* and *Daphnia* species, and larvæ of *Corethra*, have developed the typical pigmentation of wild fish. They have bright red spots on both sides of the body, the tip of the adipose fin and the dorsal and ventral edges of the tail are also red, the pectoral and pelvic fins are bright orange and the skin of the belly golden. The concentration of carotenoids and the ratio of lutein to astacene are of the same order as found for wild trout.

CAROTENOID VALUES OF THE SKIN AND FINS OF EXPERIMENTAL AND WILD TROUT

	Lutein	Astacene	Total carotenoid (estimated as lutein)
Wild trout	120	75	230
Depigmented trout	20	Negligible	25
Trout reared in aquarium on 'natural' food	90	80	200
Depigmented trout fed on fresh salmon ova for 35 days	80	65	160
Trout fed with pure carotenoids in arachis oil:			
b-carotene	15	Negligible	15
Lutein	30	,,	35
Astacene	20	,,	25

The estimations are based on comparison with standard solutions of lutein and astacene, and were made with a photo-electric colorimeter using a filter with maximum transmission about 480 mμ. All values are expressed as γ per gm. of fresh tissue.

Attempts to increase the carotenoids of depigmented aquarium fish by feeding them earthworms injected with solutions of pure carotenoids in arachis oil have been disappointing. Yearling fish received in this way several milligrams each of *b*-carotene, lutein or astacene—amounts many times greater than the whole carotenoid content of wild fish of the same size. No increase of pigmentation was observed, and the carotenoid content of the skin and fins remained at a low level. On the other hand, a group of depigmented fish fed on whole fresh ova of salmon, which contain considerable amounts of lutein and astacene, as well as carotene in lower concentration, showed a rapid increase in pigmentation of both xanthophores and erythrophores. After 35 days of this diet the carotenoid content of the skin and fins of some fish of this group approached the level found in wild fish. The remainder of the group had become depigmented once more three months after reverting to a diet of meat and worms.

Several possibilities present themselves to account for the failure to effect with preparations of pure carotenoids the degree of pigmentation achieved by a diet of 'natural' foods. Hydroxy-carotenoids usually occur in animal tissues in the form of esters or conjugated with protein, and it would not be surprising if the processes of separation and purification involved irreversible changes in the molecule, rendering it incapable of being utilized by the fish. Astacene at least is known to be a reaction product of astaxanthin, which is itself usually extracted from animal tissues as an ester, and it is possible that lutein also may undergo a similar transformation. Alternatively the efficiency of absorption of the arachis oil solution in the gut of the fish may be very low; no attempt was made in these experiments to measure the amount actually absorbed. Again, there may be a simple quantitative explanation for the failure. Estimations I have made recently of the carotenoids of the stomach contents of freshly caught wild trout have yielded surprisingly high values. The most striking were obtained from fish which had been feeding mainly on *Daphnia longirostra* (18 of 25 fish examined from a single reservoir during June and July). Some stomachs contained as much as 0·25 gm. dry weight of *Daphnia*, and yielded up to 1,200 γ of astacene and 400 γ of xanthophylls, the latter estimated as lutein. These values agree well with those obtained from samples of the zooplankton of the same reservoir, which consisted at the time of about 85 per cent *Daphnia longirostra*, the rest mainly *Cyclops* species, and which gave 6,520 γ of astacene, 1,385 γ of xanthophylls and 120 γ of carotenes per gm. dry weight. Clearly the quantities of carotenoids ingested by fish feeding on such a rich source, neglecting any derived from other food, are much greater than the limited amounts of crystalline preparations with which it has so far been possible to supply them. It may well be that even in wild trout the efficiency of absorption of carotenoids is low, or that much of it is utilized in other ways, of which the only example we have any knowledge at present is the conversion of some carotenes to the vitamins A. If this is the case, the proportion available to the chromatophore cells may be small even under the most favourable conditions.

It is hoped to publish later a more detailed account of these and further experiments.

Spontaneous Occurrence in *Lythrum salicaria* of Plants Duplex for the Short-style Gene

The continuation of the work with the purple loosestrife, *Lythrum salicaria*, previously reported[1-4], has confirmed the tetrasomic inheritance of the factor for mid-style. Lacour's determination of the somatic chromosome number as sixty suggests, therefore, the existence of fifteen quadruplets of homologous chromosomes. Since the short style is epistatic to mid, it is possible by legitimate crosses between short- and mid-styled plants to build up genetic constitutions up to four genes for the mid-style; all these appear to be phenotypically alike, or, in other words, the mid-style gene appears to be completely dominant.

In legitimate pollination not more than one parent can be short. Many shorts tested by crosses with long-styled plants have shown themselves to be simplex, containing only a single gene for short-style. Illegitimate short-by-short matings offer peculiar difficulties, and have so far been unsuccessful. It is theoretically possible, however, that simplex short plants should produce, by a process of double reduction, a minority of duplex gametes.

Recent tests involving a large number of second backcross progenies have shown that this does actually occur, and have provided a source of material duplex for short, which is of immediate importance in studying the relations of the genes for short and for purple (*v* pink) flowers which are linked in inheritance. The first indication was a small progeny grown in 1946 giving

Short purple	Short pink	Non-short purple	Non-short pink	Total
24	9	0	5	38

In the light of the larger progeny grown this year from the same plant as seed parent, crossed with pink longs, there can be little doubt that in the chromosomes carrying short its constitution is

$$RS/rS/rs/rs,$$

where R stands for purple, r for pink. It is also duplex M_2m_2 at the mid locus.

This year's progeny has yielded

Short purple	Short pink	Non-short purple	Non-short pink	Total
68	55	4	13	140

About fifty of the short purples from these have been crossed to long pinks to determine the relative frequencies of the ten possible types of gamete. The changed ratio of pink to purple is probably due to better scoring of this rather difficult factor.

One consequence of this finding is that wild cross-pollinated populations must contain, in very unequal numbers, fifteen different genotypes in respect of the factors for mid- and short-style. Of these, one only is long-styled, four are mid-styled and ten short-styled. The approximate relative frequencies to be expected in Nature are given in the accompanying table for a population of 1,000.

		s_4	Ss_3 Short	S_2s_2 Short
m_4	Long	333·3	177·4	2·248
Mm_3	Mid	275·9	113·3	1·435
M_2m_2	Mid	52·14	33·23	0·421
M_3m	Mid	4·925	4·862	0·062
M_4	Mid	0·324	0·320	0·004

No plants triplex or quadruplex for short can be produced by legitimate pollination.

Gonadal Hormones and Mineral Balance in the Domestic Fowl

It is established that the pullet coming towards the beginning of laying begins to retain calcium and phosphorus at an increasing rate[1,2]. In some cases the rate of retention may be of the order of 0·4–0·5 gm. calcium per diem.

We have sought to imitate this effect in the sexually immature pullet (aged 10–14 weeks) by means of gonadal hormones. The hormones were normally administered in six equal doses on alternate days over a twelve-day period. Œstradiol dipropionate (Ciba) alone to total amounts of 6 mgm., 12 mgm. or 24 mgm., or testosterone propionate alone to total amounts of 8 or 4·5 mgm., failed to increase the rates of retention of calcium and phosphorus significantly over those shown by control pullets. When the œstradiol dipropionate treatments were combined with the testosterone propionate treatment, then the rates of calcium and phosphorus retentions were increased over those shown by the controls to a highly significant degree. No analogous effect was shown by testosterone propionate in respect of the elevation of serum calcium and plasma phosphorus fractions evoked by the œstrogen treatments, although the combined œstrogen and androgen treatments intensified the hypertrophy of the oviduct induced by œstrogen.

The only previous experiments known to us on the effects of gonadal hormones on the calcium balance of birds are those of Clavert and Benoit[3], who secured a sharp increase in calcium retention by adult male pigeons following a single injection of 0·5 mgm. œstradiol dipropionate. It remains uncertain, however, how far the results of their experiments were conditioned by the possible presence of endogenous androgen. We are inclined to the view, therefore, that the increased rates of retention of calcium and phosphorus which take place during the

10–14 days before the pullet begins laying are conditioned by androgen as well as by œstrogen, and that the well-known androgen activity in the sexually maturing pullet (manifested by the familiar reddening and hypertrophy of the comb at the outset of laying) has a physiological significance in relation to calcium metabolism.

In the course of our work we have noted that the œstrogen treatments, while raising the serum calcium, serum riboflavin[4] and plasma inorganic lipid and phosphoprotein phosphorus, nevertheless bring about a decrease in serum citric acid concentration. Citric acid is related on one hand to skeletal metabolism[5] and on the other to gonadal hormone activity, for Shorr, Bernheim and Taussky[6] have shown that œstradiol benzoate increases citric acid excretion in women.

We hope to publish a fuller account of this work at a later date.

Use of Small-size Plots in Yield Surveys

I am glad that my note[1] has induced Prof. Mahalanobis to set down his results on plot-size bias[2]. Since the publication of his paper on the Bihar Crop Survey (1945), the position has gradually altered. In 1946 Prof. Mahalanobis recommended plots ranging from 50 to 100 sq. ft. [3] without giving any reasons or experimental data for discarding plots smaller than 50 sq. ft. In his present note the range has been further extended to include plots of 200 sq. ft., and the standard procedure adopted at present is stated to be to obtain concentric circles of 12·57, 50·27, 100·88 and 201·06 sq. ft. The advantage claimed in favour of these circles is that the variation in yield between sub-samples supplies an excellent internal control. Whether this refers to the variation in the estimates of yield or of variability from different sub-samples, the advantage does not really exist, because the estimates of variability as well as those of average yield are found to be biased in the case of small-size plots[4].

The principal advantage of small plots of the size used by Hubback and by English and American workers is that their produce can be handled by the experimenter himself without the use of hired labour. This advantage is of no effect with the concentric sub-samples at present used by Prof. Mahalanobis. Indeed, apart from being agriculturally inconvenient, as pointed out by Dr. Panse[5], the cost and effort involved in harvesting them would far exceed that required for harvesting a single large plot of 1/80 acre as adopted in the Indian Council of Agricultural Research surveys. Further, as labour is paid on a daily and not hourly basis under Indian conditions, the cost of harvesting is also not affected by small variations in size.

The limit at which the bias becomes negligible will vary with the crop and the agency carrying out the experiments. Even if it is demonstrated that plots of, say, 50 sq. ft. give unbiased estimates when handled by trained statisticians, this would be of limited practical value, especially in India, where the employment of a special agency is out of the question and the experiments have necessarily to be carried out by the local departmental staff in the course of their normal duties. All the investigations carried out by the Indian Council of Agricultural Research were planned with this objective in view. The results show that even with the best supervision and training it is not unlikely that plots up to 200 sq. ft. may give biased results. In the experiments reported by Dr. Panse, plots of 218 sq. ft. were found to give an over-estimate of yield. These results conclusively support the adoption of large plots of the size 1/80 acre or thereabout adopted by the Indian Council of Agricultural Research in its yield surveys.

On the question of the explanation of the observed bias, Prof. Mahalanobis suggests that the bias is more likely to be due to the experimenter tending to favour more fertile patches by shifting the exact location of the random point in the field than to the unconscious inclusion of the border plants inside the plot. I do not share this view. In the experiments conducted in Moradabad District, the starting point of the plot was located, by means of a pair of random numbers, under the direct supervision of statistical officers. Bias would appear to arise from the fact that even when the point of location is randomly fixed under adequate supervision, the field worker inevitably encounters a difficulty in deciding whether to include the border plants inside the plot or to exclude them. As the contribution of even a single plant to the harvested produce is appreciable in small plots, it is to be expected that the tendency regarding unconscious inclusion (or exclusion) of border plants inside the plot should materially influence the yield estimates. That appears to me the real explanation of the observed over- or under-estimation in experiments with small plots.

The danger of under-estimation due to the sagging of stretched ropes in using comparatively large plots to which Prof. Mahalanobis refers exists only in theory; for sagging is only one of the large number of small compensating errors arising in the marking of the plot. The net result of these errors is negligible in comparison with the amount of harvested produce when the plot size is sufficiently large, as will be clear from my own results[6], which show that the yield estimates from 1/80 acre plots are in agreement with those from harvesting the whole field and, therefore, free from bias. The actual existence of under- or over-estimation from any source has to be established by experimentation.

Prof. Mahalanobis has also raised the question of the reliability of the results and has emphasized the importance of arranging work in the form of interpenetrating samples. This point is not relevant to the subject-matter under discussion; but in my opinion these checks are not of any value in providing evidence on the reliability of field work. This point will be discussed elsewhere.

FRIEDEL-CRAFTS CATALYSTS IN POLYMERIZATION

KINETIC MEASUREMENTS AND THE ROLE OF WATER

By PROF. R. G. W. NORRISH, F.R.S.,
AND
K. E. RUSSELL
Department of Physical Chemistry, Cambridge

THERE has been reported a critical minimum catalyst concentration of 0·03 per cent in the low-temperature polymerization of isobutene in the liquid phase using boron trifluoride, aluminium chloride or titanium tetrachloride as Friedel-Crafts catalyst[1]. Direct mixing in the liquid phase is, however, impracticable owing to the great velocity of reaction, and any results obtained in this way are subject to uncertainty. In the work described below we have succeeded in devising a technique which enables a mixture of monomer and catalyst to be prepared at temperatures below their reaction point. Their vapours are mixed at pressures measured directly on a glass spoon gauge[2], and the gaseous mixture slowly frozen to the solid state in liquid air. At this temperature there is no reaction, but when a mixture of boron trifluoride and isobutene prepared in this way was allowed to warm up to −140° C. (the melting-point of isobutene) very rapid polymerization suddenly set in, as was indicated by a sharp rise in the temperature recorded by a copper-constantan thermocouple. We were able to show that the minimum concentration of boron trifluoride required is dependent on the degree of purification of the reactants, a value of 0·03 per cent boron trifluoride being reduced to 0·006 per cent by repeated distillation.

Because of the difficulty of obtaining kinetic measurements for the fast reaction in the liquid phase, a less active catalyst was sought. Measurable rates were obtained with stannic chloride, the polar diluent ethyl chloride being used to keep the system homogeneous. It soon became apparent, as has also been found qualitatively by Plesch, Polanyi and Skinner[4] using titanium chloride as catalyst, that the presence of water in the system is paramount, and the following measurements were therefore carried out to determine quantitatively the effect of metallic halide, and water as co-catalyst on the reaction.

The reaction was followed by a dilatometric method. For this purpose the components, including water, at measured pressures in the gas phase were frozen down separately into a special form of dilatometer; this could be sealed off from the apparatus and was so constructed as to allow of mixing by shaking. The rates of reaction were followed at a temperature of −78·5° C. afforded by solid carbon dioxide and ether. There is no induction period, and a decrease in volume occurs which is here assumed proportional to the extent of polymerization. (Owing to adsorption, water vapour in a glass apparatus does not obey Boyle's Law; by coating the inside of the apparatus with a hydrophobic monolayer in the manner described by us[3] this difficulty was overcome, and the pressure gave an accurate measure of the quantity of water added to the system.)

All materials were purified by repeated distillation *in vacuo*, but there were still minute quantities of impurities (including water) in the monomer and diluent, and it is probable that these have some effect on the course of the reaction.

For stannic chloride 1·15 per cent, isobutene 20 per cent, ethyl chloride 78·8 per cent, and a reaction temperature of −78·5° C., the effect of added water up to 0·43 per cent on the initial rate of polymerization is shown in Fig. 1.

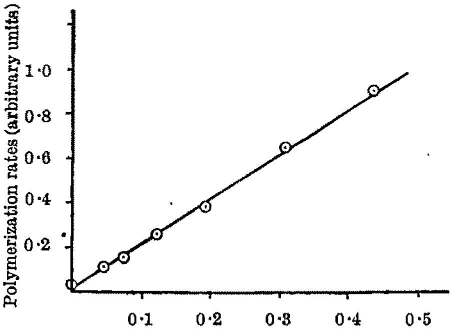

Fig. 1

Even in the absence of added water, there is still a rate of polymerization corresponding to the presence of about 0·015 per cent water. The graph clearly shows, however, the importance of water on the mechanism of the reaction.

The effect of stannic chloride concentration on the reaction rate is shown in Fig. 2.

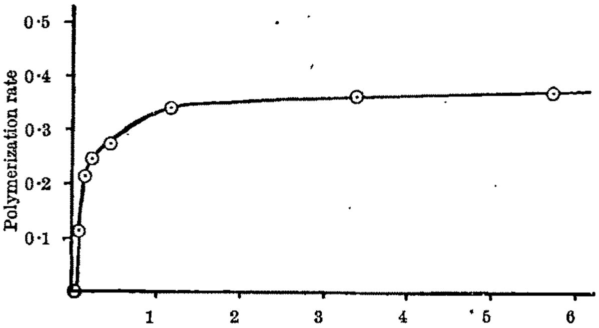

Fig. 2

It is clear that both water and the metallic halide are essential to the catalysed reaction in the liquid phase, and we conclude that a soluble hydrate is formed and functions as the active catalyst. The minimum concentration of metallic chloride below which no polymerization occurs is rather less than half the percentage of added water. When the concentration of stannic chloride was less than about one fifth that of the added water, a white solid was observed at the bottom of the dilatometer. Thus the minimum catalyst concentration is probably due to the removal of the metallic halide by excess water to give an insoluble hydrate with no catalytic activity, and should be dependent on the concentration of water in the system. Then, as the concentration of the stannic chloride increases relative to the water, there comes a stage when a lower, soluble, catalytically effective hydrate is formed, perhaps conforming to a mass action law. With more than 1 per cent stannic chloride, and 0·18 per cent of water, the rate does not increase appreciably. The precise nature of the hydrate is not certain, but neither a monohydrate nor a dihydrate is excluded by the results expressed in the graph.

When the monomer concentration is increased, the normal effect on the rate may be masked by the decrease in dielectric constant of the system and the reduced solubility of the hydrate. With 1·15 per cent stannic chloride and 0·18 per cent water the variation in rate with monomer concentration is shown in Fig. 3.

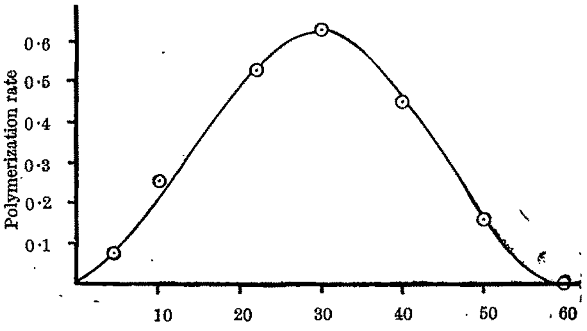

Fig. 3

A maximum rate is observed with 30 per cent monomer; there is no indication of a threshold concentration of 10 per cent isobutene referred to by Plesch, Polanyi and Skinner[4]. Since the dielectric constant of the medium changes rapidly with monomer concentration, a means of keeping it constant must be devised before the quantitative dependence of rate on monomer concentration can be given.

The effect on the rate of polymerization of the inhibitors ethyl alcohol, tertiary butyl alcohol, diethyl ether, and acetone was investigated by adding 0·3 per cent of each to a reaction mixture already containing 0·18 per cent water. The mixtures were not always homogeneous because of the low solubilities of the complexes at −78·5° C. All these substances reduced the rate to less than one fifth of its normal value, and it was observed that the molecular weight was also considerably reduced. The hydrocarbons 1-butene and 2-butene halved the normal rate with concentrations of 2 and 6 per cent respectively.

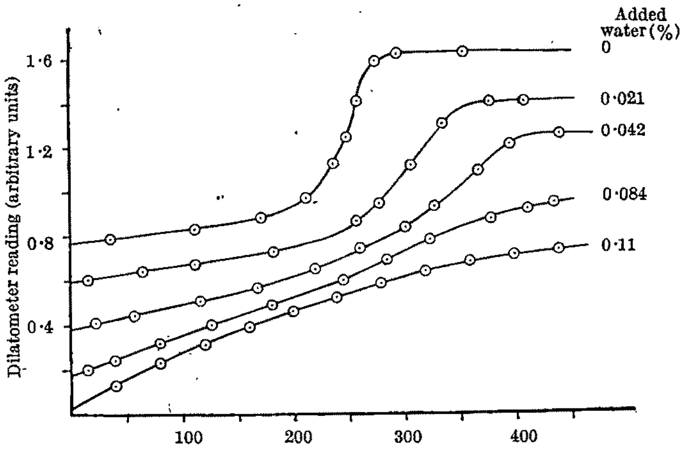

Fig. 4. Common origin moved for clarity

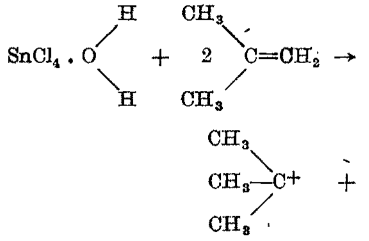
In the absence of added water, no polymerization was observed when 0·3 per cent of ethyl alcohol, tertiary butyl alcohol, diethyl ether and acetone were added to 1·15 per cent stannic chloride and 20 per cent monomer in ethyl chloride. It is therefore probable that these substances cannot replace water as co-catalysts in low-temperature polymerization.

Polymerizations involving very small quantities of added water (less than 0·1 per cent) have been followed through to completion, and the course of the reactions is shown in Fig. 4. The rates of reaction in those systems containing the least water are subject to an acceleration in the later stages of the reaction, the acceleration occurring the sooner and being the more marked the lower the concentration of water. This is reminiscent of a similar phenomenon observed in the free radical polymerization of methyl methacrylate, and shown by Norrish and Smith to be due to a decrease in the coefficient of chain termination consequent upon the considerable increase in viscosity of the medium in the later stages of reaction[5]. It is probable that a similar explanation holds here, for the chain-length and the consequent increase in viscosity are found to be greater the smaller the content of water.

A tentative picture of the kinetic mechanism may be achieved if we assume that chain propagation is initiated both by positive and negative ions derived from the hydrated stannic chloride; for example:



Chain propagation then occurs by successive addition of monomer units to the ionized complexes so that there are both positive and negative growing chains; and if termination results from the mutual neutralization of oppositely charged chains it can be understood how the coefficient of termination can decrease with increasing viscosity.

It can be shown that under such conditions the rate of polymerization is proportional to the square root of concentration of catalyst. The results obtained above are in agreement with the conclusion that the concentration of catalyst is proportional to the square of the concentration of water and the first power of the stannic chloride. When, however, the latter is in large excess, the concentration of catalyst is controlled by the water and is independent of the metallic halide. It is conceivable that the equilibrium

$$SnCl_4 + 2H_2O \rightleftharpoons SnCl_4 . 2H_2O$$

would conform to these requirements; but further evidence is required and any definite conclusion must be held in suspense.

A RADIO-FREQUENCY ION SOURCE WITH HIGH PERCENTAGE YIELD OF PROTONS

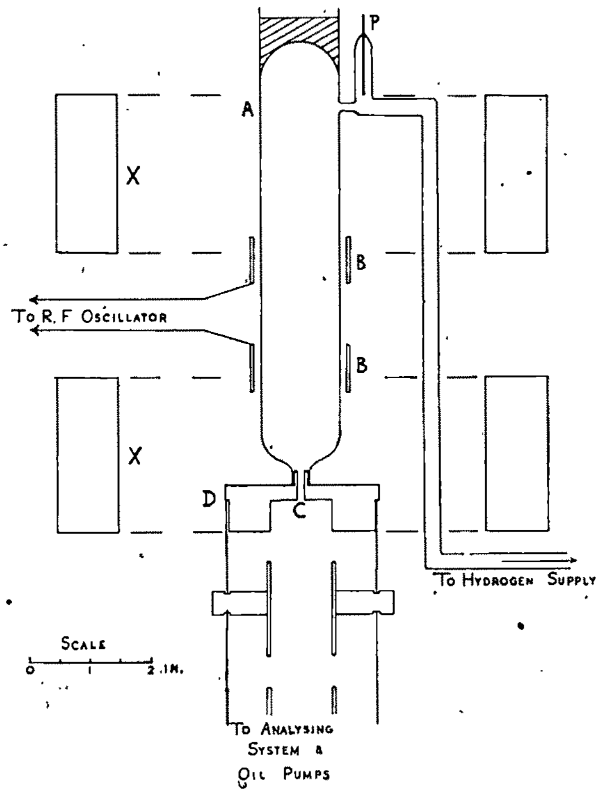
By J. G. RUTHERGLEN* and J. F. I. COLE
Department of Natural Philosophy, University of Glasgow

IN a recent communication in *Nature*[1] a description was given of a new type of ion source. This source gave a high beam current for a low energy input, but no results were given for the yield of protons as compared with diatomic (H_2^+) and triatomic (H_3^+) ions. We have recently undertaken an investigation of ion sources with the object of making a source suitable for use with a 1 MV. accelerator tube, and throughout these investigations have made quantitative measurements of the percentage yield of protons by magnetic resolution of the beam. Using the source described by Thoneman[1], we were unable to obtain more than 5 per cent of the beam as protons, the remainder being approximately equally divided between H_2^+ and H_3^+ ions.

We conclude from our investigations that the following conditions are necessary for the production of a high percentage yield of protons in discharges at pressures of the order of 10–50 microns: (i) The walls of the vessel in which the discharge takes place must be made of clean glass, and the area of metal exposed to the discharge should be kept to a minimum, presumably in order that the recombination of atomic hydrogen shall be reduced as much as possible. (ii) The ionization density in the discharge should be as high as possible.

The diagram shows an experimental arrangement satisfying these conditions which gives satisfactory results. The discharge is maintained in a 'Pyrex' tube *A*, 1¼ in. in diameter, by a radio-frequency voltage at a frequency of 180 mc./sec. applied between two external cylindrical brass electrodes *B B*. A pair of Helmholtz coils *X X* provide a constant magnetic field, adjustable from 0 to 300 gauss, parallel to the axis of the discharge tube. When the magnetic field is raised gradually from zero, a critical value of the order of 100 gauss is reached at which the brightness of the discharge increases and the colour shows a very marked reddening. The effect of the magnetic field is presumably to maintain the path of the electrons, which are oscillating under the influence of the radio-frequency field, along the axis of the discharge tube, and hence increase their life-time for producing ionization. This resultant increase in ionization density causes an increase in the percentage of atomic hydrogen in the discharge tube, which shows itself as an increase in the intensity of the Balmer spectrum relative to the molecular spectrum and hence as a reddening of the colour. We have found that this reddening is always associated with an increase in the measured proton percentage in the emergent beam, and may say in general that a steely blue colour indicates less than 20 per cent protons and a bright red colour indicates more than 50 per cent protons. Increase of the magnetic field beyond this critical value gives no appreciable increase of proton yield.

The ions are extracted from the discharge through the exit canal *C*, ⅛ in. in diameter by ½ in. long, in the aluminium block *D* by applying a potential of the order of 3 kV. between it and the probe *P*. The tungsten probe is set back in the side tube through which the hydrogen enters the discharge tube in order to minimize its effect as a surface for recombination of atomic hydrogen. Secondary electrons which are produced by ions striking the walls of the exit canal are accelerated up the axis of the discharge tube, and it was found necessary to cool the top of the tube with a small oil bath. For analysis the emergent beam is accelerated, usually to 15 kV., by an electrostatic lens system which focuses it on to a slit, ¼ in. wide, at a distance of 36 cm. from the exit canal *C*. The beam passes through the slit into a Faraday cylinder. A 'straight through' analyser, with crossed magnetic and electrostatic deflecting fields, is built in between the focusing system and the slit, at a mean distance of 23 cm. from the slit. A small permanent magnet provides the magnetic deflecting field of about 400 gauss over a distance of 1¼ in. The electrostatic field is provided by two parallel plates 1¼ in. long, spaced ¾ in. apart, between which deflecting potentials up to 3 kV. can be applied.



Typical operating conditions for the source shown in the diagram are as follows: radio-frequency power into the source 30 watts, magnetic field 130 gauss, pressure ~15 microns, hydrogen consumption 15 c.c./hr., probe potential 2·8 kV., focusing potential 14 kV., probe current 6 ma., total focused beam current to Faraday cylinder 400 μa., resolved proton current 240 μa., resolved diatomic ion current 110 μa., resolved triatomic ion current 12 μa., resolved current of heavy ions 40 μa. It will be seen that protons comprise 60 per cent of the emergent beam.

To illustrate the importance of reducing the area of exposed metal surfaces to a minimum, we may mention that we have obtained proton percentages as high as 75 in an earlier source in which the ions were extracted through a hole ⅛ in. in diameter in the glass end of the discharge tube, although, in this particular case, we were unable to obtain beam currents in excess of 50 μa. In the source shown in the diagram, the outside diameter of the top of the aluminium exit canal exposed to the discharge was 3/16 in.

---

* Nuffield Fellow.

We believe that proton currents of considerably more than 240 μa. can be obtained with this type of source by improvement of the extraction and focusing arrangements and increase of radio-frequency power.

---

PSYCHROMETRIC OBSERVATIONS IN THE LOWER ATMOSPHERE

A VERY valuable series of nearly five hundred psychrometric measurements in the lowest 1,000 ft. of the atmosphere were made over Massachusetts Bay, under the general direction of Mr. Donald E. Kerr, by members of the Radiation Laboratory, Massachusetts Institute of Technology, in the summer and autumn of 1944. They are discussed by Richard A. Craig in *Papers in Physical Oceanography and Meteorology*, **10**, No. 1, published by Massachusetts Institute of Technology and Woods Hole Oceanographic Institution, also described as "Contribution No. 362 from the Woods Hole Oceanographic Institution", which is dated November 1946.

These measurements were not made primarily for their meteorological interest, but in connexion with studies concerning the propagation near the sea surface of radio waves of the order of centimetres or a few metres in length, because they yielded information about vertical distributions of refractive index of air for radio frequencies. The necessity for these special observations arose because the kite soundings made by G. I. Taylor in 1913 from the whaling ship *Scotia* over the Grand Banks of Newfoundland, and those made in 1915 on the U.S. Coastguard cutter *Seneca* for a more extended area, did not show the vertical distributions of temperature and humidity in sufficient detail to help very much in the propagation problem. The discussion is in two parts. Part 1 describes the organisation of the work and some of the thermodynamics and kinematics involved in such studies. It also describes the method of presentation adopted in Part 2, where fifty-one selected soundings are discussed with all available supplementary information, such as the past history of the air currents at different levels and synchronous observations made at shore stations.

A psychrograph which measured dry- and wet-bulb temperatures by means of electrical resistors was developed for the work. It is referred to as the M.I.T. psychrograph (Kerr, 1947) but is not here described in detail. It was mounted for the most part on a Curtiss monoplane or a twin-engined Beechcraft, but for a few of the soundings was hung beneath a slowly ascending Navy airship. Meteorological investigations on such a lavish scale are scarcely likely to be undertaken in Great Britain for many years to come. They are a good example of the American flair for well-organised co-operative research. At the same time, we may take pride in the fact that the influence of Taylor on meteorological theory arising originally from his theoretical treatment in 1913–14 (when he was Schuster reader in meteorology at Cambridge) of the kite ascents made on the *Scotia*, has not lessened in the intervening thirty-three years. This is illustrated by the use made by Craig, in the discussion of these American soundings, of Taylor's development of the theory of mixing of air masses of different temperature and vapour pressure.

Although no single point of outstanding meteorological interest is brought to light by the soundings in Massachusetts Bay, no serious student of synoptic meteorology can afford to overlook them, because of the insight which they give into the changes that are always taking place in air masses as a result of radiation, conduction and turbulence, as they pass over land and sea, or over seas in which there is a steep horizontal gradient of temperature. A good proportion of the soundings were made in fog, and these are of particular value in connexion with forecasting.

THE MILLPORT MARINE BIOLOGICAL LABORATORY

EVIDENCE of increasing activity in the field of marine biological research is afforded in the annual report of the Scottish Marine Biological Association for the year 1945–46. Research at the Millport Laboratory under the direction of Mr. R. Elmhirst has during the year in question covered a number of problems the solution of which has direct economic value.

Work on British agar, for the development of which we are indebted to Dr. S. M. Marshall and Dr. A. P. Orr, has been continued on collections of *Chondrus crispus* from Wales and Cornwall. The agar from *Chondrus*, like that from *Gigartina*, is satisfactory for bacteriological work, and there is also a considerable commercial outlet for a dried preparation of the viscous extract obtained from these weeds by boiling. The commercial harvesting of *Gigartina* in the Clyde area has become a regular summer occupation for local people.

Dr. Marshall and Dr. Orr have also made further experiments on the effects of different fertilizers on the phytoplankton in Loch Craiglin, and on the growth of oysters. It was found that oysters could be satisfactorily fattened in containers put out in Loch Sween. The oysters were well filled and of excellent flavour.

There is also promise of a possibility of breeding oysters successfully in the area, though the year may have been unusually suitable owing to the exceptionally fine summer.

The team of workers on antifouling research led by Mr. K. A. Pyefinch, and previously under the Iron and Steel Institute, passed on January 1, 1946, to the control of the British Iron and Steel Research Association. During the year a general report was produced including an account of the biology of the more common fouling organisms. A paper has also been published on "Methods of Assessment of Antifouling Compositions". Some interesting biological details are given in the annual report under review, including the biology and settlement of *Tubularia* larvæ and the settlement of marine worms. The latter indicates the probability of the importance of the physical nature of the substratum in influencing settlement as shown by the pioneer work on metamorphosis in polychæte larvæ by D. P. Wilson.

The report also contains summaries of research on the ecology of Mollusca carried out by Prof. C. M. Yonge and Dr. A. C. Stephen.

It is satisfactory to note that a number of visiting research workers went to Millport during the year, and that there are general signs of increasing post-war activity. The Millport Laboratory is situated in an area with much sheltered water and an abundant flora and fauna. It is most suitably placed for research of many kinds, and is within easy reach of deeper oceanic water with its rich and varied fauna. It is to be hoped, therefore, that in order to cope with the increasing demands for marine biological research in the British Isles we shall see in the near future an expansion of the staff and equipment at Millport. Included with the equipment should be a larger research vessel in order that the range of observations at sea may be extended.

MANAGEMENT OF RESEARCH

THE lecture on "The Organisation of Industrial Research" which Dr. R. P. Russell, president of the Standard Oil Development Co., delivered on June 9 to the Industrial Research Committee of the Federation of British Industries was far more than a factual review of one of the world's largest research organisations or its achievements in the petroleum industry: it was a masterly analysis of factors and conditions determining the success of industrial research in any field and an outstanding contribution to what may be termed the philosophy of research. Research activity in his own Company, he said, began in 1919 with a group of twenty-six people: to-day the staff includes 2,456 technologists, engineers, assistants and clerical personnel all engaged exclusively on research and development projects, as well as several hundred working on laboratory phases of direct operating problems and an engineering staff of more than five hundred. Dr. Russell computed that this expansion had brought a return of £15,400 of additional profit for each £1,000 expended on research and development, and he believes that without research and development any company or industry would stagnate and in time lose most of its business to more far-sighted competitors.

Dr. Russell does not, however, claim that research is a universal panacea or even that it is the keystone in the arch of industrial production. It is rather one link in a chain which comprises also natural and human resources, production management, effective sales and distribution and courageous executive management. Nor is the 'economic climate' alone important: a sound 'political climate' is also an important factor in successful industrial enterprise, for such a climate inspires the sense of security which gives people confidence to assume the risks involved in any important new venture. These factors are all important and must be firmly interlinked if our objectives of satisfying human needs are to be achieved. Progress depends essentially on whether our political and economic system strengthens or weakens the factors which form the links in the industrial chain.

At the outset, Dr. Russell disposes of the idea that adequate expenditure of money or of men on research is all that is required. It is a matter of team-work and co-operation and of ensuring the conditions most favourable to the generation of ideas. Effective co-operation, for example, in the solution of a research or development problem means that everyone participating knows the problems which exist and recognizes their relative importance. This applies no less to the engineering organisation, the production group and management than to the research and development team itself, and the first point which Dr. Russell makes is that information about a project on which the research organisation is engaged must flow freely throughout the whole organisation, horizontally as well as vertically. Insulation of the research and development department must be avoided at all cost, and continuing contacts fostered at each operating level.

The interlacing of information in this way is not only a valuable incentive but also has certain practical advantages in facilitating the rapid application to one project of new knowledge gained by other units. Nor is the exchange of information confined within the firm. Dr. Russell stresses the value of close contact with work going on outside, of attendance at scientific and technical meetings and of the use of consultants as well as research agreements with universities, sometimes on very broad lines and sometimes for specific problems of immediate importance. Here Dr. Russell makes no distinction between fundamental and fact-finding research, and the value of the universities as the centre of the search for knowledge for its own sake is rather taken for granted. Expenditure of his Company on research by outside consultants amounts to about two per cent, and on research grants to universities to more than three per cent, of the total salaries of the technical and professional staff. Apart from this, research workers are encouraged to devote about ten per cent of their time to work on original ideas; and while the value of competition as a stimulus is fully appreciated and encouraged within the firm itself, the practice is never allowed to impede the free and complete flow of all information from unit to unit.

Dr. Russell indicates clearly the relations of mutual trust which exist in the research organisation he describes, and that positive factor is one the importance of which can scarcely be exaggerated. In itself it fosters the sense of individual responsibility which calls forth the maximum ingenuity and initiative; and in establishing the right atmosphere it probably contributes even more than the study of individual characteristics and capabilities, though that, too, is important. No less important than encouraging the generation of ideas is the avoiding of practices which tend to discourage them, and some of the observations Dr. Russell makes here are substantiated by bitter experience in Great Britain between the two World Wars. As he truly remarks, the loss of morale and effectiveness through a sudden and drastic reduction of the technical staff is out of all proportion to the monetary saving achieved.

There is much in this lecture for those responsible for the management of research to ponder, all the more in that Dr. Russell recognizes that, in the United States as in the United Kingdom for some years to come, the available scientific man-power will be insufficient to meet all the demands for trained staff, and it will be imperative to ensure that the best possible use is made of the resources that are available. Nor is it a matter for the industrialist alone. It is not necessary to go all the way with Dr. Russell in his belief in the necessity for a free and truly competitive system to agree with him that political conditions can be of great importance from the point of view of incentives. The idea of public service, as Sir Oliver Franks noted in his recent lectures, can be at least as satisfying an incentive as the purely financial one.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, October 20

King's College (in the Department of Civil and Mechanical Engineering, Strand, London, W.C.2), at 5.30 p.m.—Prof. S. J. Davies: "Mechanical Aids to Improved Thermal Operations". (Further lectures on October 27, November 3, 10 and 17. The lecture on November 10 will be given by Mr. L. J. Clark, who will deal with Special Considerations in the Production of Gas for Towns.)*

Royal Institute of Chemistry, London and South-Eastern Counties Section (joint meeting with the Luton Scientific Association, in the Lecture Hall, Public Library, Luton), at 7.30 p.m.—Films and Discussion on Water Treatment.

Chemical Engineering Group (joint meeting with the Yorkshire Section of the Society of Chemical Industry, at Leeds).—Mr. H. C. Millett: "Some Experiences in the Heavy Chemical Industry" (preceded by a visit to Charles Brotherton Chemical Engineering Laboratory).

Tuesday, October 21

University of London (at the Royal Holloway College, Englefield Green, Surrey), at 2 p.m.—Prof. S. Tolansky: "Recent Developments in Multiple Beam Interferometry". (Further lectures on November 4, 11, 18, 25 and December 2.)

Society of Chemical Industry, Agriculture Group (in the Chemistry Department, Royal College of Science, Imperial Institute Road, London, S.W.7), at 2.30 p.m.—Dr. G. A. Cowie: "Fertilizer Requirements of Wheat as Determined by Field Trials".*

Institution of Post Office Electrical Engineers (at the L.T.R. Headquarters Refreshment Club, Waterloo Bridge House, London, S.E.1), at 5 p.m.—Mr. W. H. Scrivener: "Engineering Control Statistics—Some Difficulties and Possible Solutions".

University College London (in the Physiology Theatre, Gower Street, London, W.C.1), at 5.15 p.m.—Dr. Bernard Katz: "Transmission and Excitation in Nerve and Muscle". (Further lectures on October 28, November 4, 11, 18 and 25.)*

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. B. S. Bramwell: "Galton's 'Hereditary Genius' and the Three Following Generations since 1869".*

Institution of Civil Engineers (at Great George Street, London, S.W.1), at 5.30 p.m.—Mr. H. E. Hogben: "Modern Aids to Navigation by Radio".

Society of Engineers (at 17 Victoria Street, London, S.W.1), at 6.30 p.m.—Dr. G. E. Blythe: "Fine Grinding in Industry".

Wednesday, October 22

Manchester Joint Research Council (in the Albert Hall, Peter Street, Manchester), at 10.30 a.m.—Conference on "Market Research".

Institution of Electrical Engineers, Transmission Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m. —Prof. W. J. John: Inaugural Address as Chairman.

Society of Chemical Industry (at the Royal Institution, Albemarle Street, London, W.1), at 6.30 p.m.—Sir Frederick Keeble: "Some Aspects of the Work of H. E. Armstrong" (Second H. E. Armstrong Memorial Lecture).

Thursday, October 23

Chemical Society (joint meeting with the Hull and District Section of the Royal Institute of Chemistry and the University College Scientific Society, in University College, Hull), at 6 p.m.—Prof. D. H. Hey: "Addition Polymerisation".

Royal Aeronautical Society (in the Lecture Hall of the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Sir William T. Griffiths: "The Problem of High Temperature Alloys for Gas Turbines".

Textile Institute (joint meeting with the Industrial Group of the Manchester Statistical Society, at 16 St. Mary's Parsonage, Manchester), at 6.30 p.m.—Mr. E. Lord: "Some Practical Aspects of Sampling with special reference to the Cotton Industry".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Prof. E. G. Cox: "Crystallographic Technique and its Chemical Significance" (Tilden Lecture).

Royal Institute of Chemistry, London and South-Eastern Counties Section (at Medway Technical College, Gillingham), at 7.30 p.m.—Scientific Film Display, followed by Discussion on Local Activities.

Friday, October 24

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Geophysical Discussion on "Atmospheric Turbulence".*

Chemical Society (joint meeting with the Southampton University College Chemical and Physical Societies, in the Physics Department, University College, Southampton), at 5 p.m.—Prof. C. K. Ingold, F.R.S.: "Isotopes and Molecular Spectra".

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Presidential Address.

Sheffield Metallurgical Association (joint meeting with the Royal Institute of Chemistry, at 198 West Street, Sheffield), at 7 p.m.—Dr. H. J. T. Ellingham: "Chemical Metallurgy".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Senior Agricultural Economist in the Department of Agricultural Economics—The Director, Nottingham University College School of Agriculture, Sutton Bonington, Loughborough (October 25).

Scientist (Grade III) with good general graduate scientific training and some experience in physiology or biology, for the London Headquarters of the National Coal Board—The Ministry of Labour and National Service, Technical and Scientific Register, Room 669, York House, Kingsway, London, W.C.2, quoting G.433/47A (October 25).

Assistant Lecturer in Dyeing in the Bradford Technical College —The Director of Education, Town Hall, Bradford (October 25).

Lecturer in Mechanical Engineering—The Principal, Dudley and Staffordshire Technical College, Dudley (October 25).

Senior Assistant in Mechanical Engineering, a Senior Assistant in Metallurgy, a Senior Assistant in Structural Engineering, and a Lecturer in Science, at the Constantine Technical College—The Director of Education, Education Offices, Woodlands Road, Middlesbrough (October 25).

Head of Department of Electrical Engineering, Oldham Municipal Technical College—The Director of Education, Education Offices, Union Street West, Oldham (October 25).

Lecturer in Physiology—The Secretary, Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.2 (October 27).

Chemist-in-Charge at the Royal Ordnance Factory, Birtley, Co. Durham, under the Ministry of Supply—The Ministry of Labour and National Service, Technical and Scientific Register, Room 669, York House, Kingsway, London, W.C.2, quoting F.810/47A (October 28).

Officers to undertake original investigations with poultry in (*a*) Nutrition, (*b*) Pathology, (*c*) Endocrinology, and (*d*) Animal Behaviour, at the Poultry Research Centre, Edinburgh—The Secretary, Agricultural Research Council, 6a Dean's Yard, London, S.W.1 (October 31).

Librarian (temporary) at the Marine Laboratory, Torry, Aberdeen—The Ministry of Labour and National Service, Room 669, York House, Kingsway, London, W.C.2, quoting G.38/47A (October 31).

Director of Design (Ref. C.583/47A) with long experience in chemical plant design; a Director of Design (Ref. C.584/47A) with exceptional organising ability and a first-class experience of mechanical engineering; a Director of Design (Ref. C.585/47A) with an extensive knowledge of the design of heavy civil engineering works and of mechanical plant; and a Director of Engineering Services (Ref. C.586/47A) with an extensive experience in engineering design and preparation of specifications and plans for construction, at the Department of Atomic Energy, Risley, Warrington—The Ministry of Labour and National Service, Technical and Scientific Register, Room 660, York House, Kingsway, London, W.C.2, quoting the appropriate Ref. No. (October 31).

Principal of the Gloucester Technical College—The Education Officer, Belsize House, Brunswick Square, Gloucester (November 1).

Graduate (M.Sc. or B.Sc. in Chemistry) as Research Assistant to the Leather Research Association, New Zealand Government—The High Commissioner for New Zealand, 415 Strand, London, W.C.2 (November 7).

Warden of Malham Tarn Field Centre—The Director, Council for the Promotion of Field Studies, 10 Exhibition Road, London, S.W.7 (November 10).

Lecturers in Physiology, Bacteriology, Biochemistry (2), Dental Prosthetics, Orthodontics and Dental Anatomy, in the King Edward VII College of Medicine, Singapore—The Secretary, Inter-University Council for Higher Education in the Colonies, 8 Park Street, London, W.1 (November 12).

Senior Scientific Officer at the Royal Air Force Acoustics Laboratory, London—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2017 (November 27).

Director of Fisheries in Hong Kong—The Director of Recruitment, Colonial Service, 15 Victoria Street, London, S.W.1.

Plant Physiologist by the Research Division of the Department of Agriculture and Forests, Sudan Government—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1, endorsed 'Plant Physiologist'.

Lecturer in the Department of Mathematics—The Principal, Technical College, Huddersfield.

Chemist in the Department of Agriculture in the Colonial Agricultural Service, British Guiana—The Director of Recruitment, Colonial Service, 15 Victoria Street, London, S.W.1.

Lecturer in Physics at Leeds College of Technology—The Director of Education, Education Department, Leeds 1.

Senior Geologist in Nigeria—The Director of Recruitment, Colonial Service, 15 Victoria Street, London, S.W.1.

Physicist (male or female) to the Radiotherapy Centre—The Medical Superintendent, St. Luke's Hospital, Guildford, Surrey.

Director of Research—The Chairman of the Council, Coal Tar Research Association, Gas Industry House, 1 Grosvenor Place, London, S.W.1.

Director of Research (physicist)—The Chairman, Federated Foundries, Ltd., 75 Hawthorn Street, Glasgow, N.

Assistant in the Department of Chemistry (with special qualifications in Physical Chemistry)—The Secretary, The University, Aberdeen.

Professors of Pharmacology and Physics, and Assistant Professors of Pharmacology, Pathology and Biology, at the Royal College of Medicine, Baghdad—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.N.18525.

Lecturer in Mathematics principally to Engineering Degree students, a Lecturer in Electrical Engineering to National Certificate and Degree students, and a Lecturer in Mechanical Engineering to National Certificate and Degree students—The Principal, College of Technology and Arts, Eastlands, Rugby.

Demonstrator in the Department of Physics—The Registrar, University College, Singleton Park, Swansea.

TEACHERS IN TECHNICAL COLLEGES AND SCHOOLS

IN an article in *Nature* of June 22, 1946, the salary scales of teachers in technical schools in Great Britain were criticized in the following terms: "the very comprehensive character of the Burnham scales for technical teachers militates against their effectiveness in the realm of higher technology. The scales for technical teachers have, for reasons which it is not easy to understand, been closely tied to those applicable to teachers in primary and secondary schools. For the large majority of teachers in technical institutions they are in fact identical with them, and only in the provision of separate scales for heads of departments in technical colleges and the introduction of a senior assistant scale for a limited number of technical teachers do they differ from the school salaries. The scales are designed to cover the whole range of further education from the teachers in a small country technical institute to the lecturer in a major technical college, the junior lecturer in which, however advanced and important his work, may be on the same salary scale as the teacher in the smallest institution."

These words are no less applicable to the recently announced proposals of the Burnham Technical Committee which will, if accepted by the constituent bodies, become operative on April 1, 1948. The proposals made by the Technical Committee follow closely those put forward by the main Committee, which is responsible for the recommendations in respect of teachers in primary and secondary schools. They include, for example, the same basic scale, the same proposals regarding the 'London Area', the same provision for graduates, and the same intention to abolish the merger clause. Again, in the provision of posts of special responsibility, local education authorities are left to determine the number of such posts (between 20 per cent and 27½ per cent of the number of full-time teachers other than principals) to whom the Burnham Technical Report applies (which is, admittedly, an improvement on the present position of between 19 per cent and 21 per cent); but the financial limits are, as in the main report, between £50 and £150 per annum for men, and between £40 and £140 per annum for women.

More satisfactory, however, are the proposed scales for senior assistants and heads of departments. In these a real attempt has been made to recognize the validity of the claim—made in the McNair Report on the Training of Teachers—that a senior lecturer in a technical college is responsible for work not dissimilar from that of a lecturer in a university, and that the head of a large department in a technical college has responsibilities for organisation and research comparable with those of a university professor. The proposed salary scale for senior assistants is £700–£25–£800 per annum for men, and £560–£20–£640 per annum for women. For heads of departments, it is proposed that there should be four fixed grades with a maximum in the fourth grade of £1,250 per annum for men and £1,000 per annum for women, and a flexible fifth grade which will allow local education authorities to fix, in agreement with the Minister of Education, a salary beyond these limits for a departmental head in a large college.

Even if these scales are agreed, much must depend on the policy adopted by local education authorities in appointing senior assistants and in grading departmental heads. But the difficulties which local education authorities will encounter—and the variations which must inevitably occur between the practice in one area and another—are not likely to be lessened by the failure of the Burnham Technical Committee to establish salary scales for principals. Since failure to do so in 1945 is an important factor affecting adversely the recruitment of highly qualified men and women possessing suitable training and experience to the staffs of major technical colleges, it is certainly to be hoped that the Minister of Education will interpret generously the provision which empowers him to report to the Committee in 1951 on the review of principals' salaries which local education authorities are required to make in the light of the other recommendations in the report. Since it is not unreasonable to suppose that the recommendations of the Percy Committee regarding the National Council of Technology and the regional advisory councils will, within the next three years, be fully implemented, the time may well be opportune in 1951 for the Minister to consider drastic changes in the administration and finances of technical education in Great Britain.

CHEMICAL BASIS OF MUSCLE CONTRACTION

Chemistry of Muscular Contraction

By A. Szent-Györgyi. Pp. vi+150. (New York: Academic Press, Inc.; London: H. K. Lewis and Co., Ltd., 1947.) 4.50 dollars.

THIS book is largely a summary of the work of the Szeged school carried out just before or during the war years, and is not designed for the consideration of past or contemporary studies on muscle and muscle proteins. It is, indeed, an intensely individual book, representing a rather novel and daring approach to the problem of physiological contraction. This, no doubt, explains the widespread interest which Prof. Szent-Györgyi has aroused, and among the background of polemical discussion which such interest has invoked, the reviewer must attempt an impartial judgment which is not shocked into scientific conservatism by novelty, but is based solely upon objective consideration of experimental data. Unfortunately, a critique along these lines is not wholly possible: some results are personally communicated; others are derived from data not yet accessible; others, still, do not conform with more recent experiments as described in a 'stop-press' section (Part IV). In these circumstances, it seems most profitable to discuss only the more important features which are especially relevant to the problem of muscle biochemistry, leaving the interpolated section on "The Continuum Theory" (Part III) for other comment.

The outstanding contribution is the discovery that the muscle fibril contains an, as yet, ill-defined protein termed 'actin' which interacts with myosin to give an actomyosin complex. Actomyosin is influenced by traces of adenosinetriphosphate in two different ways, according to the ionic strength of the medium. In 0·5 *M* potassium chloride, the complex exists as a thixotropic gel which is broken up into its component molecules in presence of adenosinetriphosphate; in 0·05 *M* potassium chloride, however, the gel on addition of adenosinetriphosphate exhibits an intense synæresis (termed by Prof. Szent-Györgyi 'contraction'), giving a dense precipitate of actomyosin containing 50 per cent of its weight of protein, whereas myosin precipitates ordinarily contain only 2–4 per cent of protein. It is this latter effect which forms the basis of various speculations on muscle contraction.

It is clear that the actin–myosin interaction is an unusual one, and more recent work in Britain and Denmark has emphasized this fact in the finding that the sulphydryl groups of the myosin partner play an essential part. Obviously, the urgent need, before attempting to relate the actin–myosin–adenosinetriphosphate interrelationships to muscle contraction, is to resolve the mechanism of this synæresis. Does it involve the aggregation of micelles and the squeezing-out of intermicellar water as in the formation of the fibrin clot? Or does it involve an intramolecular saturation of side-chain linkages? There are no really adequate data to decide these facts, and to transpose this system to muscle itself as the basis of the contractile process is not to offer an explanation of how muscle contracts; the clockwork of the model is missing. There might be some virtue in the model if it conformed with accepted concepts of the structure of the fibril; but in the assumption that the contracting elements have a spiral structure, it opposes the evidence of the electron microscope and X-ray diffraction. Moreover, the experiments relating to the energetics of muscle contraction, even if valid, are not specific to the theories advanced and reveal nothing of the molecular mechanism of contraction.

In all that concerns the properties of proteins there are serious misconceptions. The whole treatment of the binding of ions by myosin is both confused and confusing, and governed by physico-chemical inventions which not only conflict with each other but also with experimental fact and with physico-chemical theory. It is assumed, for example, that when a neutral salt is added to a negatively charged myosin precipitate, cations are adsorbed in such a way that the protein becomes isoelectric. The extension of this adsorptive process to the point where the protein dissolves lands the author into great difficulties, as a reading of the section on p. 114 adequately shows. Other claims, that myosin is not a globulin, and that it is genuinely crystalline, are quite inadmissible.

To the biochemist, the enzyme sections present a bewildering display of new facts and conclusions which must certainly invite both interest and criticism. No final judgment can be attempted, since much of the experimental detail is not available. There is a tendency, however, to attribute an astonishing variety of findings to an astonishingly simple system. It is said that myosin–adenosinetriphosphatase, acting in conjunction with 'protein II', effects first a breakdown to adenosinediphosphate; phosphate is then transferred from the pyro- to the amino-group to give a new adenosinediphosphate, which is then simultaneously de-phosphorylated and deaminated. In absence of protein II, myosin–adenosinetriphosphatase is stated to produce not only adenosinediphosphate but also an adenosine-tri- and diphosphate dinucleotide. Obviously, if these reactions occur, a rather complex enzyme system is present. Again, the metal activation of adenosinetriphosphatase gives rise to a complex picture which is more easily accommodated by assuming the presence of other enzymes, and these effects have, in fact, been discussed in contemporaneous studies. There are strong suggestions that some of the reactions induced by proteins I and II are due to Kalckar's myokinase: protein I plus myosin plus adenosinediphosphate produce a synæresis of actomyosin, due to the biosynthesis of adenosinetriphosphate, presumably by the agency of myokinase. Because the partially purified protein I contains a chromoprotein (fluorochrome), it is tacitly assumed that this is the enzyme concerned in the above reaction. These several points serve to implement the contention that the findings must be supported in due course by the most exhaustive experimental evidence. In this connexion, it is necessary to stress that to prove the existence of an isomeric adenosinediphosphate or of a new dinucleotide is a most difficult task; one recalls inevitably the controversies on the structure of adenosinetriphosphate itself, and the careful studies on the nucleotide of heart muscle, claimed by some to be a diadenosine pentaphosphate, by others a mixture of adenosine-tri- and diphosphate, and in any event a problem still unresolved.

These are not the only aspects of the enzymic material which even in the most favourable light must remain contentious; equally so are the conception of 'protins', the implication that succinic dehydrogenase is an actomyosin, and that adenosinetriphosphatase is a property of 'contracted' actomyosin. For the unwary reader, several errors are apparent: the ordinate of Fig. 16; the salt concentration, at the top of p. 28; and the fibre dimensions, p. 32.

Although objective scientific criticism must be unfavourable, and although it is difficult to separate the gems of fact from the trinkets of fancy, so deftly are they intermingled, the book possesses many virtues. It is eminently readable, imaginative, stimulating, sometimes humorous, and reflects Prof. Szent-Györgyi's own delightful and unique personality. Though it may very profitably be read by all critical people, it should not be recommended to uncritical and over-receptive students. In the last analysis, the hard core of the book, the myosin–actin–adenosinetriphosphate interrelationship, holds great possibilities for the future understanding of muscle biochemistry and biophysics.

KENNETH BAILEY

PEONIES

A Study of the Genus Pæonia

By F. C. Stern. Pp. viii + 156 + 15 plates. (London: Royal Horticultural Society, 1946.) 63*s*.

ALL who are interested in the genus *Pæonia*, whether botanists or gardeners, will welcome Colonel Stern's critical review, and the Royal Horticultural Society is to be congratulated in producing such an imposing volume. The author's skill as a horticulturist has earned him a high reputation in the acclimatization of plants, and this talent has been directed during the last twenty-eight years to the cultivation of wild species of peony. With his study of living material, examination of dried specimens in the principal herbaria, and survey of the literature bearing on the genus *Pæonia*, the author is well equipped to present an authoritative account. He freely acknowledges the assistance which he has received from professional botanists in the elucidation of taxonomic and nomenclatural problems.

Chapter 1 contains a conspectus of the genus in which the species are grouped in three sections: *Moutan*—an Asiatic group of four species with woody stems and with prominent development of the disk at the base of the carpels; *Onæpia*—consisting of two herbaceous species, native in western North America, in which the disk is prominently lobed; *Pæon*—a widespread section of thirty-seven species which are herbaceous with no conspicuous lobing of the disk and which extend from south-western Europe to Japan. An interesting feature in the section *Pæon* is the occurrence of eight pairs in which the plants are practically identical, except that in one member of each pair the carpels are glabrous while in the other they are densely pubescent. There is no geographical segregation in each pair, and Colonel Stern regards the distinction as only of varietal status. Four new subsections are defined and typified, and artificial keys are given to the sections, subsections, species and varieties; and it may be mentioned that the keys, tested on fresh and preserved material, have proved a satisfactory guide to the identity of the plants. The morphology of the genus is discussed, and an assessment is made of the characters of systematic value.

In the final section of the first chapter there is an account of the cytology of the genus, and a list is given of the chromosome numbers of the different species as determined at the John Innes Horticultural Institution. It is possible to distinguish cytologically the New World species from those of the Old World, but otherwise the size and morphology of the chromosomes is very uniform. In certain closely allied species, difficult to distinguish on their external morphology, chromosome numbers have been accepted as taxonomic criteria, and in the case of *Pæonia* this policy may be justified. Many systematists, however, will disapprove of the recognition of species based solely on differences in chromosome number and, should similar examples be multiplied, it may be necessary to devise a separate nomenclature for cytological categories.

Chapter 2 contains a summary of the distinguishing characters of peony species and a detailed account of their geographical distribution. The sections are reviewed individually and the distribution of the various groups is shown very clearly on beautifully delineated maps. In discussing the geographical range of the members of the genus, Colonel Stern suggests that the cytology of the species indicates relationships which, when considered in association with the present distribution and comparatively recent climatic history, give a clue to their evolutionary spread. His discussion is certainly suggestive, and his speculations, though applying to a relatively small group of plants, will be carefully weighed by students of plant geography.

The genus is holarctic, with two species in western North America and the others with a wide range across the Old World. The closely related North American species are diploid, and in their botanical characters are most akin to the shrubby Chinese species. In Europe and the outlier in North Africa, groups of allied species and varieties occupy the same geographical area, and in each of these groups one species is diploid with a much more restricted range than the others, which are tetraploid. Excluding the representatives in the Caucasus and Asia Minor, the Asiatic groups of species and varieties (which contain what are probably the most primitive species, including herbaceous members with more than one flower to a stem and also shrubby species) are all diploid, with the exception of one group which has a diploid species in Japan and a connected tetraploid on the Chinese mainland. Why in Asia and America do the diploid species so greatly outnumber the tetraploids, and why do tetraploids predominate in Europe? Colonel Stern suggests that events during and after the glacial period may have determined the cytological constitution of species and so influenced their distributional potential.

In Europe, by the southerly displacement of the vegetational zones during glacial times, the existing diploid peonies were forced into the Mediterranean basin and on to some of the Mediterranean islands. It is supposed that as a result of this geographical disturbance tetraploid species were derived from the diploids and, when conditions ameliorated, the more vigorous and better adapted tetraploids spread rapidly northwards and also crossed into north Africa. This hypothesis may explain why, in the European groups of related species occurring in the same areas, the diploid species have a much more restricted range than the derivative tetraploids. The diploid peonies of eastern Asia, it is surmised, are ancient relicts, which survived *in situ* during the glacial epoch and thus avoided genetic disturbance leading to tetraploidy. Cytological investigation of certain related genera and species may assist in the interpretation of their geographical range; but the genetic factor, while obviously important, must not be emphasized to the exclusion of other considerations. It seems significant that the genera in the British flora notorious for the numbers of 'critical' or endemic species have all been disrupted to some extent in the glacial periods, and the complications in these groups may be due to genetic disturbance resulting from climatic upheavals.

The individual species and varieties are fully described and discussed in Chapter 3; a full synonymy is given and specimens examined are cited. Unfortunately, scant mention is made of the collections, including types, preserved in the British Museum, and this disregard has resulted occasionally in an inadequate appreciation of the geographical range. For example, *P. Delavayi*, according to the monograph, is confined to Yunnan; but there is a specimen (*Kingdon Ward* 12214) from the Po-Yigrong region of south-east Tibet which was named by the author and yet is omitted from his enumeration. A more serious oversight has led to the treatment of Pallas's *P. hybrida* as a species *non satis nota*. Type-material is, however, preserved in the British Museum and, by Colonel Stern's classification, is referable to *P. anomala* var. *intermedia*.

One would have expected, in a book bearing the *imprimatur* of the Royal Horticultural Society, that some attempt would be made to deal with the hosts of named hybrids and forms which are more generally cultivated than the wild species; but for information on these, gardeners must still refer to nurserymen's catalogues. Apart from these criticisms, the enumeration reveals a careful and well-considered survey of the genus.

A fully documented chronological bibliography of the genus occupies Chapter 4, and a history of the species in cultivation with practical advice on their culture concludes the volume. The list of peony species and synonyms forming Appendix 1 gives no references to the text and could have been conveniently included in the general index.

"A Study of the Genus Pæonia" is a credit to the author, artists, printers and publishers, and sets a high standard in botanical and horticultural writing. The book is a splendid and timely token of British scholarship and craftsmanship, and the freshness of the beautiful coloured plates calls for a special word of praise. Perhaps it is not too much to hope that the Society will sponsor further volumes in this style; they could scarcely fail to appeal to botanists and gardeners alike. GEORGE TAYLOR

TECHNICAL MATHEMATICS

Applied Mathematics for Engineers and Physicists
By Dr. Louis A. Pipes. Pp. xiii+618. (New York and London: McGraw-Hill Book Co., Inc., 1946.) 27*s*. 6*d*.

THIS text is an excellent addition to the increasing number of books which seek to acquaint the physicist and engineer with the modern methods of mathematics as applied to technical problems.

The subject-matter is based on lectures given by the author at the Graduate School of Engineering, Harvard University, and covers both basic mathematics and relevant applications to physical and engineering problems such as conduction of heat and vibrations of beams.

Though general in scope, the book should be valuable to the specialist as a work of reference which can be consulted to ascertain the power and field of application of particular methods such as the use of matrices or of the operational calculus. Having chosen a method promising for his particular problem, the research worker can then proceed, if necessary, to a specialist book, references to which are given by Dr. Pipes at the end of each chapter.

On a point of detail, it is noted that two lists of Laplace transforms are given in widely separated chapters, involving considerable duplication, the first list being in excellent tabular form, whereas the second is given in the less easily consulted form of consecutive equations without tabular division. In future editions it is suggested that these lists could be amalgamated into one table at the end of the book for ease of reference. Apart from this minor criticism, the text appears well written and arranged and includes problems for the reader to test his skill or the power of a method.

Though primarily designed for the graduate, this text could well take a place on the bookshelf of the brighter undergraduate, since the subject-matter is unusually wide in range, covering, for example, both a first introduction to complex numbers in the second chapter and the analysis of non-linear oscillatory systems in the final chapter.

In general, this book can be recommended to all engineers and physicists interested in improving the range and power of the mathematical tools at their command. E. N. FOX

A Practical Course in Agricultural Chemistry

For Senior Students of Agriculture, Dairying, Horticulture and Poultry Husbandry. By Frank Knowles and Dr. J. Elphin Watkin. Second edition. Pp. xi+216. (London: Macmillan and Co., Ltd., 1947.) 12*s.* 6*d.* net.

LABORATORY handbooks of agricultural chemistry for students are not numerous, and the second edition of Knowles and Watkin's useful practical course is especially welcome at present, when laboratories and teachers are so hard pressed to cope with their swollen classes.

This book adequately covers the subject, and one feels that it has been written by men of experience who are used to helping students and are well acquainted with their difficulties in laboratory manipulations. While not claiming to be a textbook, this manual includes sufficient background to explain the import of the exercises described.

Since the first edition, in 1936, new commodities, concepts and methods have come into use, and the authors have revised and enlarged their text accordingly. The section on soil has been improved by additional exercises on moisture relationships, nitrogen economy and cation-exchange aspects of the soil, while the recent prominence of triple superphosphate, agricultural salt and sewage sludge is recognized in the fertilizer section. There are new exercises on vitamin C and on blood, and the section dealing with dairy products has been enriched by amplification of the pages on the freezing point of milk and on dairy detergents. The detection of mineral deficiencies in plants by leaf analysis breaks new ground here, and the concluding section on fungicides and insecticides now includes exercises on the newer products such as D.D.T. and 'Gammexane'.

These various additions have expanded the work by twenty-six pages, but its clear type and prominent headings make it easy to use and read.

Microfotografia e Macrofotografia

Principi e applicazioni della technica microfotografia al laboratorio di recherche scientifiche e industriali. Per Prof. Edgardo Baldi. Pp. xii + 349 (18 plates). (Milano: Ulrico Hoepli, 1946.) 900 lire.

THE Italian title of this book may well prove misleading to English readers. Its subject is in the main photomicrography (not microphotography), with a relatively small section dealing with such matters as still photography and document reproduction.

The author is a biologist, and it is therefore not surprising to find that the physics of the microscope is treated from an elementary point of view. Nevertheless the first two chapters cover all that is essential to an understanding of the role of illumination and the formation of images. Brief mention is made of the phase-contrast technique, which is now enjoying such a deserved vogue. The Köhler system of illumination is given justifiable emphasis, and detailed instructions are provided for adjusting the illuminating system. The second chapter concludes with descriptions of the well-known types of condensers and vertical illuminators—these latter including that of Lieberkühn and the Leitz 'Ultropak'.

Chapters 3 and 4 deal with both ordinary and special types of equipment, including objectives and eyepieces. Chapter 5 treats the question of macrophotography, and Chapter 6 that of filters. Chapter 7 gives a general outline of the procedure for taking a photomicrograph, while the final chapter concerns itself with photomicrography in the infra-red and ultra-violet regions respectively.

There are a number of elementary errors in this book. The camera head indicated in Fig. 133, for example, is shown with a semi-reflecting prism of a type which would ensure that no image could possibly be formed on the photographic plate. A great deal of care is called for in the preparation and publication of a handbook of this type, care which in this case one feels has occasionally been lacking. The book contains little information not already available elsewhere, and is consequently not likely to be in great demand outside Italian-speaking countries.

H. H. HOPKINS

Atlas of Histopathology of the Skin

By Prof. G. H. Percival, Prof. A. Murray Drennan and T. C. Dodds. Pp. viii + 494. (Edinburgh: E. and S. Livingstone, Ltd., 1947.) 75*s.* net.

APART from the comprehensive and justly famous "Pathology of the Skin" of Macleod and Muende, British medical literature is lacking in works on this subject. This new book is smaller in scope than the former, the authors confining themselves, not too rigidly, to the commoner skin diseases and restricting description and discussion to an adequate minimum. Details of pathological technique are entirely omitted.

The 376 illustrations are all photomicrographs in colour, and the reproductions, with few exceptions, are most exact at all magnifications. Those dermatologists who have, in the past, decried photographs as less revealing than drawings will do well to study these pictures.

The book is intended to be a companion to textbooks of dermatology and a guide-reference for dermatologists and pathologists. In these aims the authors have been most successful. Special praise is due to Mr. T. C. Dodds, the technician and photographer, and to the printers for the excellence of this publication. It will be welcomed by everyone in the field of dermatology and may stimulate the laggards in this neglected field of investigation.

An Insect Book for the Pocket

By Edmund Sandars. Pp. 350 (36 plates). (London: Oxford University Press, 1946.) 10*s.* 6*d.* net.

THE objects of this little book are to aid its users in identifying and learning something about the larger insects in the British Isles. Owing to the number of species—more than twenty thousand—the size criterion is adopted in order to keep the subject within reasonable compass. Only species exceeding half an inch in body-length, or one inch in wing-span, are dealt with, and, in this way, the number of families to be described is reduced from more than three hundred to about 130. Groups consisting of very small insects only come in for mention if they are of special interest or of economic importance. It is surprising how well this very arbitrary standard has worked out in this manual. It is an accurate and well-written little book. The coloured plates and text-figures are adequate for their purpose and there is a useful list of works for consultation. A pleasing feature running through the pages is the indication (in brackets) of the meanings of the generic and specific names referred to: also the price of the work is very reasonable under present-day conditions.

A. D. I.

PENICILLIN AND OTHER ANTIBIOTICS

THE concentrated research effort on antibiotic substances during the last six or seven years has provided results and new materials of the greatest interest to medical science, to chemistry and to general biology. The relatively recent nature of this work, most of which was undertaken as a direct consequence of the clinical success of penicillin, has obscured to a great extent the fact that work on antibiotics had been carried on since the middle of the nineteenth century, in the fields both of medical microbiology and of plant pathology. The organisers of the symposium on "Penicillin and other Antibiotics" at the British Association meeting at Dundee, by bringing together Sections B (Chemistry), I (Physiology) and K (Botany), sought to arrange their programme so that these various aspects were touched upon.

Sir Alexander Fleming gave a general introduction to the symposium. Defining an antibiotic as "a substance, produced by a living body, which is toxic to micro-organisms", he pointed out that neither the effect nor the word antibiotic is new. Antagonism between bacterial colonies or between mould colonies and bacteria is a commonplace of clinical laboratories, well known for years before the chance contamination which led to the discovery of the effect of penicillin. Even in the nineteenth century an antibiotic preparation from *Pseudomonas pyocyanea* known as pyocyanase was used therapeutically, though with little success. All the chemical antiseptics in use at the time of his work on penicillin were more toxic to leucocytes than they were to bacteria, and penicillin was the first substance encountered which destroyed bacteria without having any appreciable effect on human leucocytes. Penicillin retains prominence in its low toxicity, and this is largely responsible for its great clinical success.

Sir Alexander then briefly surveyed the steps leading from his original observations to the large-scale production of pure crystalline penicillin. In the course of this he commented on the highly valuable free interchange of results between academic workers and industrial firms both in Great Britain and the United States, which was in large measure responsible for the rapid progress made during war-time, and regretted that now, in conditions of peace, such co-operation appeared to be much less easily attained. He concluded by remarking that though penicillin has its disadvantages, such as instability in aqueous solution and a definitely limited range of organisms against which it is clinically effective, it is nevertheless not going to be easy to find a drug superior to penicillin in its own field.

Dr. E. Chain dealt with the chemical structure and biological activity of four types of antibiotic. His first type was the polypeptide group comprising gramicidin, tyrocidine and gramicidin *S*. Each of these substances is a simple polypeptide, the proportions of the constituent amino-acids being known in each case. A point of chemical and biological interest is that each of these contains amino-acids of the 'unnatural' *d*-configuration. Gramicidin *S* is chemically the simplest of these substances. The basic unit is a pentapeptide containing the following arrangement of amino-acids:

α-*l*-valyl-*l*-ornithyl-*l*-leucyl-*d*-phenylalanyl-*l*-prolyl.

The gramicidin *S* molecule is probably built up of two of these pentapeptides, linked in a cyclic structure. These substances are both bacteriostatic and bactericidal, active mainly against Gram-positive bacteria. They are not efficient chemotherapeutic agents owing to too great a toxicity. Their high toxicity represents an interesting biochemical problem, as there is no obvious reason why a dekapeptide of the above constitution containing simple amino-acids, each of which is known to be non-toxic, should show such marked pharmacological properties. Subtilin, bacitracin and the colicines, also polypeptide antibiotics of bacterial origin, are remarkable for their high specificity. Further knowledge of their chemical structure would be of great interest, as it might lead to an understanding of the relation between the structural arrangement of the polypeptide molecule and its specific biological activity.

Helvolic acid is probably a polycyclic compound related to the triterpenes. It is highly active against Gram-positive bacteria, relatively non-toxic to mice and antibacterially active in the body. Nevertheless, it is not an effective chemotherapeutic agent in mice. Analysis of its mode of action has shown that it is purely bacteriostatic, having virtually no killing effect. The mouse has no natural resistance against *Streptococcus*, and hence helvolic acid, as it does not kill organisms, is ineffective in eradicating a streptococcal infection.

Dr. Chain next considered the only two antibiotics which have shown any practical possibility in medicine, namely, streptomycin and penicillin. Streptomycin is bacteriostatic to some organisms and bactericidal to others. It is of highest efficacy as a chemotherapeutic agent in diseases caused by those organisms which it is able to kill, such as *Hæmophilus influenzæ* and *Pasteurella tularensis*. Clinically, successes have been obtained in the streptomycin treatment of some cases of miliary tuberculosis and tubercular meningitis, but it is yet too early to evaluate finally its role as a chemotherapeutic agent in clinical tuberculosis. Streptomycin possesses certain disadvantages. Like other antibacterial bases, it is most active above *p*H 7, its activity decreasing with decreasing *p*H, and so has relatively low activity at the *p*H of many body tissues. In addition, it is not devoid of toxic effects. More important is the fact that many organisms (including *Mycobacterium tuberculosis*) develop resistance very rapidly, frequently in one or two subcultures only. However, in spite of these objections, streptomycin shows considerable promise as a chemotherapeutic agent in several diseases where penicillin is ineffective.

In dealing with penicillin, Dr. Chain pointed out the chemical novelty of the β-lactam ring in the penicillin molecule. This is responsible both for the instability that caused the initial difficulties in isolation, and for the extraordinary molecular rearrangements that can be produced by relatively mild chemical treatments. From the medical point of view, penicillin still remains unique among all antibacterial substances in that it is non-toxic, not antagonized by tissue constituents, is independent of inoculum-size and has a definite killing effect on rapidly dividing cells. With the exception of *Staphylococcus*, bacteria do not readily develop penicillin resistance.

Here the discussion was continued by Dr. J. A. Elvidge, who described work on the chemical synthesis of penicillin, with particular reference to the more recent work carried out at the Imperial College of

Science and Technology, London. Indications of successful syntheses of traces of penicillin were obtained in Oxford and in the United States in 1944, and the isolation of minute quantities of penicillin was reported by du Vigneaud in 1946. The surprising fact is that these syntheses were achieved by methods based on a mistaken view of the structure of the penicillin molecule. For a considerable time chemical evidence was unable to decide whether the now well-known thiazolidine-oxazolone or β-lactam structure was correct; a decision in favour of the latter was based on data provided by X-ray crystallography and infra-red absorption spectra. The syntheses mentioned above were based on the supposed thiazolidine-oxazolone structure; that of du Vigneaud being by the condensation of 4-methoxymethylene-2-benzyl oxazolone with penicillamine. However, only traces of penicillin have been produced by this method, which appears to be of little practical value, and consequently at the Imperial College routes of a more promising aspect were sought and eventually found in methods involving thiazoline intermediates. The present state of this work was then described in some detail by Dr. Elvidge, and it was evident that further results of great interest are to be expected.

A really workable synthesis of penicillins and structurally related compounds is highly desirable. Pentenyl-, benzyl-, p-hydroxybenzyl- and heptyl-penicillin have been found naturally. Even among this relatively small number of penicillins, quite marked differences in antibacterial activity, solubility and stability are found. Particularly in therapeutic effectiveness do p-hydroxybenzyl- and heptyl-penicillins differ. Hence it is possible that even more effective penicillins could exist, with more desirable physical properties—perhaps enhanced chemical stability and activity against a greater or different range of micro-organisms. Chemical methods of synthesis would make feasible the preparation of many modifications and derivatives and enable the many attractive possibilities to be investigated.

Up to this point, the discussion had centred around antibacterial antibiotics of medical interest. Another approach was made by Dr. P. W. Brian, who spoke on fungistatic antibiotics, considering the matter particularly from the point of view of the plant pathologist. A number of most important plant diseases are caused by soil-inhabiting fungi which attack the roots, vascular systems and base of the host plants. It was found early in the investigation of these diseases that if the host plant were grown in sterile soil inoculated with the pathogenic fungus, the symptoms observed were usually far more severe than if a normal untreated soil were used. It was widely deduced from this observation that some of the normal saprophytic members of the soil microflora are 'antagonistic' to the pathogen, and many such antagonistic organisms were in due course isolated.

Later workers found that in many cases treatment of an infected soil with a culture fluid on which the antagonistic organism had grown was as effective as inoculating the soil with the organism itself. A particularly well worked out research on these lines was that of Weindling (1931–41) on the role of the fungus *Trichoderma viride* in antagonizing the damping-off disease of *Citrus* seedlings caused by the fungus *Rhizoctonia solani*. He found that the disease could be much reduced by acidifying the soil. This was effective, not by directly reducing the vigour of the *Rhizoctonia*, but by encouraging the growth of an antagonistic fungus, namely, *Trichoderma*. He also found that the antagonistic *Trichoderma* could kill *Rhizoctonia* at a distance in an agar medium and that a liquid culture medium on which *Trichoderma* had grown was highly toxic to *Rhizoctonia* hyphæ. He carried this research a stage further and in 1936 isolated in pure form from such toxic culture filtrates the now well-known antibiotic gliotoxin.

Since then, many examples of the production by fungi of substances toxic to other fungi have been discovered, as well as production of such substances by other types of micro-organisms. Some of them are general poisons, toxic also to bacteria and other organisms, examples being gliotoxin, patulin, aspergillic acid, citrinin, gladiolic acid and penicillic acid. Others, such as viridin and glutinosin, are specifically toxic to fungi only. Other substances again, unlike those just mentioned, which have a definite killing effect like most synthetic fungicides, reduce the rate of fungal growth by causing marked abnormality in development; an example is griseofulvin ('curling factor'). [See also p. 574.]

Dr. Brian concluded by suggesting that antibiotics should receive more attention from the point of view of soil processes and soil-borne plant diseases than they have so far done, and that in this field many of those antibiotics which have received little attention from the medical microbiologists, owing to such undesirable properties as toxicity, may nevertheless be of the greatest significance.

The remaining two papers aimed at relating the production of antibiotics by micro-organisms to their general biological and biochemical background, Dr. J. Ramsbottom dealing with the biological, and Dr. S. E. Michael with the biochemical, aspect.

Dr. Ramsbottom confined himself mainly to consideration of production of antibiotics by fungi, but the conclusions he reached may be regarded as equally valid for all antibiotic-producing organisms. The production of antibiotic substances is part of the general problem of the relation between organisms. Organisms do not live in pure culture in Nature, but in the presence of many other kinds of organisms. All sorts of relationship may be possible between different species in a mixed population, from antibiosis to symbiosis. He recalled the original definition of antibiosis by Vuillemin, in 1889, who considered that all types of association could be placed on a scale ranging from the pure parasitism of the blight fungus (*Phytophthora infestans*) on the potato (a phenomenon he called 'antibiose'), where only one partner in the association gained any advantage, the other suffering a corresponding disadvantage, to those cases where, by mutual benefits, both partners gained, such as the relationship between fungus and alga in the lichen thallus ('symbiose'). Marshall Ward expounded similar views at the Dover meeting of the British Association in 1899. More precise definitions of the terms 'antibiosis' and 'antibiotic' than the current ones are needed, or we shall have the same confused thinking that has been associated with symbiosis, which was originally thought best exemplified by parasitism.

More recent research has shown that many of the symbiotic types of association have a chemical basis. For example, it has been found that the well-known observation that infection of orchid seeds with a mycorrhizal fungus is necessary before germination can take place is due to a need of the embryo for aneurin, which is synthesized by the fungus. Similarly, it has been found that on a vitamin-free medium neither the fungus *Mucor ramannianus* nor the yeast *Rhodotorula rubra* will grow at all. If mixed inocula are used, both organisms grow perfectly. The reason for this surprising result is that the *Mucor* is unable to synthesize the pyrimidine moiety of aneurin but is able to synthesize the thiazole moiety, whereas *Rhodotorula* is able to synthesize the pyrimidine but not the thiazole. Thus the two in association act in a complementary manner and growth becomes possible.

In view of many such instances of a chemical background for symbiotic relations, it seems possible that the production of antibiotic substances may have some significance in explaining 'antibiotic relations', whether of the nature of the parasitism of fungi on higher plants or antagonism between fungi and other micro-organisms. Various plant juices have proved to be 'antibiotic'. Fragments of an orchid tuber suppress the growth of its mycorrhizal fungus; this may be related to the fact that the fungus is always restricted to definite areas of the growing root. These facts lead to the tentative suggestion that antibiosis may on occasion be an essential ingredient of symbiosis. Dr. Ramsbottom quoted the antagonism between *Trichoderma viride* and other fungi, with its possible connexion with gliotoxin and viridin production; the antagonism demonstrated by Van Luijk in 1939 between *Penicillium expansum* and *Pythium* spp. and its possible connexion with patulin production; the relation between the wilt-fungus *Fusarium lycopersici* and the tomato plant, in connexion with production of the wilt-producing polypeptide lycomarasmin. Caution is necessary in interpreting these facts; in Dr. Ramsbottom's words "the balance [between organisms] is probably controlled *to some extent* by the ability of some organisms to produce antibiotics, though it would be teleological to suppose that they have a purposeful origin".

Dr. S. E. Michael wound up the discussion by considering the chemical structure of mould antibiotics in relation to the general metabolic chemistry of fungi. Systematic study of the metabolism of lower fungi by Raistrick and his colleagues has shown that moulds of one or of several species yield products which are closely related variants of a particular type of structure. Examples that can be quoted are the toluquinone series (fumigatin and spinulosin); the anthraquinone series of mould pigments (helminthosporin, cynodontin, ω-hydroxyemodin, catenarin and erythroglaucin); the tetronic acid series (carolic acid, dehydrocarolic acid, ascorbic acid and penicillic acid). These few examples—far from complete—show the remarkable variety of compounds found as metabolic products of moulds, and the tendency for these products to be variants of a smaller number of basic patterns of molecular structure.

A number of well-known antibiotics fall into one or other of these general classes. Those of the tetronic acid series are particularly interesting. Tetronic acid belongs to the important and widely distributed class of unsaturated γ-lactones. This unsaturated lactone structure has been found in a number of antibiotic substances, and it is of considerable interest to see how variations on this basic molecular structure affect biological activity. The whole carolic acid series and ascorbic acid are devoid of antibiotic activity. On the other hand, the antibiotics penicillic acid, patulin, vulpinic acid and protoanemonin (extracted from higher plants) are all unsaturated γ-lactones. If their structure is considered, it appears that activity is associated with an unsaturated lactone ring carrying at least one ethylenic or carbonyl radical outside the ring, and also in some cases a methoxy or other ether group attached to the unsaturated carbon atom of the ring. Where the unsaturated radical outside the ring is missing (dihydropenicillic acid, α-β-angelicalactone), or where the ether group has been replaced by a hydroxy-group (the carolic acid series), antibiotic activity is reduced or absent.

These examples show that many mould antibiotics can be recognized as variants or derivatives of structurally known metabolic products. Others, on the other hand, such as penicillin, appear at our present state of knowledge to possess chemical structures not hitherto recognized in natural products.

The wide field covered by this discussion makes it difficult for either a chemist or a biologist to appreciate the significance of all the points brought forward. Nevertheless, it is hoped that this short review will help to indicate the varied types of interest in antibiotics now being shown in different branches of science. It should also be explained that, in order to give a logical presentation of the material, the order in which the various contributions were given has been altered. P. W. Brian

CRACK DETECTION

A TWO-DAY symposium on methods of crack detection was held under the auspices of the Industrial Radiology Group of the Institute of Physics during July 18–19 in the lecture theatre of the Electric Lamp Manufacturers' Association, Savoy Hill, London.

The chairman, Mr. W. J. Wiltshire, explained that the group has recently included lectures comparing other methods of non-destructive testing with radiological methods, and the symposium was an instance of this extension of activity.

A short address was given by Dr. W. Betteridge, who explained the importance of cracks in both metallic and non-metallic components, the various means by which the main types of crack are formed, and the principal methods of detection. The latter he divided into three groups: the essentially visual methods, including the ways of making a crack more apparent, such as etching, dyeing, magnetic ink indication, etc., and radiography, the visual examination then being made on the film instead of on the actual component; the inferential methods such as the use of supersonics or of electrical resistivity, in which the presence of a crack is deduced from its disturbance of the normal lines of sound or current flow; and the mechanical methods, including proof loading, pressure testing, damping, etc.

Mr. C. Croxson dealt in detail with the application of radiography to the detection of cracks. He said that not many years ago a high-grade component containing a crack would have been immediately condemned; but nowadays repairs by excision and welding under radiographic supervision are often satisfactorily performed. A discouraging factor is the difficulty of assessing the mechanical significance of a crack by correlating radiographic results with practical experience. Penumbral unsharpness, due either to a broad focus tube or a small target-specimen distance, is not very detrimental and, within limits, may even lead to increased sensitivity; but graininess in the film is a great handicap, and the use of the finest grained film is recommended. The sensitivity of radiographic methods is higher than generally supposed, and cracks only a few ten-thousandths of an inch in width can be detected in steel plates up to half an inch in thickness if favourably oriented. The discernibility of a crack is related to the ratio of the width to the angle of inclination to the X-ray beam; but for shallow cracks, where the inclination does not noticeably change the appearance of the image, it depends on the cross-section of the crack. Mr. Croxson concluded with a number of illustrations of the application of radiography to the detection of cracks in castings, forgings and welds, and, in summarizing the usefulness of the method, said that, in his opinion, serious hot tears or cold cracks in castings could not escape detection by radiography, and the same applied to cracks in forgings provided a critical technique was used with an understanding of the probable location and direction of the cracks. In welds small cracks could escape detection, but these are usually of little practical significance.

Mr. P. Rowbotham surveyed the various visual, etching and magnetic methods of detection, and explained that for all these the best results could only be expected if the inspectors worked under optimum conditions of lighting. A trained inspector working under ideal conditions can achieve very high sensitivity. Magnifying lenses and low-power microscopes can be helpful, but the small field of view and the necessity for frequent refocusing are disadvantages. Their value is mainly in the assessment of a crack following its detection by a more sensitive method. Brief descriptions were given of several common methods of increasing the visibility of a crack, including etching, anodizing, the use of oil and chalk, fluorescent liquids, etc., all these depending on the absorption into the crack of a liquid which afterwards oozes out. Finally, the magnetic methods for ferromagnetic materials, in which the escape of flux at the crack is indicated by a detector fluid, were described. For all these methods the crack must break through the surface of the part, except that the magnetic method will reveal cracks which are only a small distance beneath the surface.

The use of electrical conductivity methods for non-magnetic metals was dealt with by Mr. A. M. Armour, who explained that while a crack will disturb the lines of current flow in a metal in the same way as the lines of magnetic force in a ferromagnetic material, the electrical method is much less sensitive than the magnetic method because of the lack of a sufficiently sensitive detector of the lines of current flow. Most success has been achieved by the use of scanning search coils coupled to an indicator to give a signal on passing the vicinity of a defect. The use of two balanced search coils symmetrically placed with respect to a primary coil has enabled relatively uniform material such as sheet or bar to be examined successfully; but the method fails when a complicated component is to be dealt with because of the disturbances introduced by changes of section. Success has also been obtained in the search for diametrical cracks in large light-alloy billets by rotating the billet in a magnetic field and causing the eddy currents produced to react on two opposed search coils. A direct-current potential drop method has also proved of value for the detection of laminations in sheet, lack of adhesion in bearing liners, etc.

Supersonic methods were described by Mr. D. O. Sproule. The shadow detection method, in which the effect of a defect on the transmitted primary beam is observed, was considered to be of low sensitivity compared with echo methods, and the method in which the reflected beam interferes with the frequency-modulated primary beam was also described as of less importance than the echo method using pulse excitation. In the latter case the primary beam consists of pulses of sound at a frequency of a few megacycles per second produced by an oscillating quartz crystal, and the reflected energy is picked up by a similar crystal in the intervals between the primary pulses. The depth of the defect is determined by the time interval between the primary and reflected pulses; but the character of the defect producing the echo is not readily determined, although, by frequency variation, defects of relatively large areas, such as cracks, can be differentiated from fine porosity. The application of the method to components of different shapes was described, and the sensitivity to such small defects as hair-line cracks in large steel billets was illustrated.

The last paper was by Mr. M. Baimler, who described the development of industrial radiology in Czechoslovakia. The general position is very similar to that in Great Britain; but the advantage of using a long anode tube, which radiates in all directions in one plane and thus enables a circle of a large number of components to be radiographed at a single exposure, was stressed; the tube-film distance of about 12 feet gives sharp definition, and the increased exposure time is more than compensated for by the number of components dealt with at one time. An ingenious screening stand for dealing with castings weighing up to about 3 cwt. was described.

In the discussion which followed, Mr. A. G. Warren made a plea for the use of the term ultrasonic to describe high-frequency sound, supersonic being used in connexion with speeds above that of sound. The need for a detector for electrical conductivity methods was met in the case of high-frequency currents by sparking across the crack, which was easily visible. He said that cracks at angles above 45° to the direction of the lines of force could easily be detected by the magnetic ink method if the flux density were high enough. Mr. Rowbotham agreed, but found it preferable to control the flux density so that the limit of sensitivity was at about 45°. Mr. Armour described a combined radiographic and magnetic method, the exposed and processed film forming the base on which the magnetic record is deposited by a special detector ink. Mr. H. Capper said that fatigue cracks are frequently missed by radiography, and complementary methods should always be applied. Permanent magnets are found useful for magnetic crack detection. Eddy current methods have been found by Mr. E. G. Stanford to be of value for checking consistency of products for dimensions, composition, temper, etc., and the changes introduced by such variables make crack detection ambiguous. Mr. D. J. Jones described the difficulty of finding longitudinal cracks in sealing wires for the lamp industry; visual examination at a magnification of 10–20 was found best. Mr. W. C. Heselwood had found the shadow ultrasonic method preferable to the potential drop method for the detection of laminations in steel plate. In answer to a question by Mr. A. Maskery on the possibility of using a single exploring head for ultrasonic work, Mr. Sproule described a method of using two balanced heads, one on a standard sample and the second exploring the test sample, defects then being indicated by a disturbance of the balance; but he thought that a single head generally gave less information than the separate transmitter and detector.

THE INTERNATIONAL UNION OF GEODESY AND GEOPHYSICS

By Dr. J. M. STAGG

General Secretary

LIKE all large families, the group of scientific unions with the International Council of Scientific Unions as foster mother has a wide range of interests: one of the elder members of the family, the International Union of Geodesy and Geophysics, is itself big enough and broad enough in outlook to find a place for sciences with superficially so little in common as geodesy and hydrology, seismology and oceanography, vulcanology and meteorology, terrestrial magnetism and atmospheric electricity. So the International Union of Geodesy and Geophysics is a real confederation of unions (or associations, as they are called in the Union), each more or less autonomous, having its own president, secretary and bureau, its own statutes and by-laws and its own procedure for dealing with the problems within its domain. In addition, there is a Commission on Continental and Oceanic Structure which has the status of an association, and, more recently formed, a primary Committee on the Social Value of the Earth Sciences to look after the broader economic, social and political implications of the Union's work. Most of the associations have a number of sections or committees specializing in various aspects of their fields of geophysics.

Though all these constituent organisations of the International Union of Geodesy and Geophysics meet at the time of the triennial general assembly of the Union, they also continue their scientific activities for the most part separately, and arrange their own meetings between assemblies as they choose. Little of this has been possible since the general assembly held in Washington in September, 1939; and yet, as the recently published report* shows, it is remarkable how quickly the Union has revived and put its house in order ready to renew its wide activities. There is little doubt that much of this quick recovery is due to the energetic and experienced work of the late general secretary, Brigadier H. St. J. L. Winterbotham. Even before the War had properly begun he had taken steps to safeguard the Union's funds and contrived to keep an emergency organisation running until the end of hostilities, although the president, Dr. la Cour, had died early in the War and contacts with other senior officers were very restricted. Some of the associations, on their side, continued their work in some measure throughout the War, supporting themselves on the annual subscriptions from their own and neighbouring countries.

As a sequel to a meeting of the Executive Committee of the Union, convened shortly after the end of hostilities, an extraordinary assembly was called in 1946 to put the Union on its post-war feet again. That assembly was held in Cambridge in 1946 and was attended by delegates from sixteen of the pre-war total of some thirty member countries. It made important decisions for the future of the Union, not the least being a radical change in the method of subscription by member countries and institutions. As with most other similar Unions, countries adhering to the International Union of Geodesy and Geophysics have paid (or tried to pay) an annual subscription determined by their population. This was manifestly unfair to countries like India and China, and had obvious results. A decision of last year's extraordinary assembly was designed to provide a remedy: in future each member country may itself choose any one of eight categories of membership, the only proviso being that the category selected has to be formally approved by the Union's council, on which every country has one representative. The category of membership determines the annual subscription to be paid, and the voting power in Council or General Assembly in discussions involving finance.

The details of this innovation have been embodied in new statutes and by-laws which were adopted by the Cambridge assembly and have since been approved by all adhering countries. These new statutes and an account of the other decisions made by the extraordinary assembly are published in the 1946 report: the report also includes brief summaries of the activities of the various associations since the Washington meeting, a list of the officers of the Union and its component organisations, and the text of an agreement recently made between the International Union of Geodesy and Geophysics (as one of the family of the International Council of Scientific Unions) and U.N.E.S.C.O. By this agreement the International Union will play its part in disseminating information on geodetic and geophysical subjects in countries where contacts on cultural and scientific matters have hitherto been few: and in return, U.N.E.S.C.O. will use its good offices to promote these contacts by financial support for publications and meetings. U.N.E.S.C.O. has already allocated grants from its 1947 budget for this purpose.

U.N.E.S.C.O. will also help in another field of the International Union's activity. Real progress in geodetic and geophysical subjects requires the closest possible international collaboration on a long-term basis. Sound theories concerning isostasy, or the figure of the earth, concerning the nature of the internal structure of the earth as revealed by earthquakes, or the form of the earth's magnetic and electrical fields, or, again, concerning ocean currents or the circulation of the atmosphere, cannot be achieved in a year or two. In each of these fields of investigation there is a great need for a central bureau, maintained on a more or less permanent basis, where at least all the main facts can be collected and made available to those specialists, wherever they be, who are capable of studying them. Since its formation in 1919 the International Union of Geodesy and Geophysics has become responsible, sometimes with other interested unions or institutions, for maintaining several such permanent or quasi-permanent services: the International Seismological Summary, the Isostatic Institute in Helsinki, the International Latitude Service, and the Bureau International de l'Heure are examples. The maintenance of these services, with their staffs and publications, has become a continuous drain on the funds of such unions as the International Union of Geodesy and Geophysics, even to the detriment of other investigations which equally require international co-operation though on a shorter term basis. Following on the U.N.E.S.C.O. agreement, it is therefore a good omen for future development in geodetic and geophysical science that U.N.E.S.C.O. will try to allocate grants for these bureaux and so relieve the International Union to engage in the many other important problems which await investigation.

---

* International Union of Geodesy and Geophysics. Report for the War Years 1939–45, with the proceedings of the Executive Committee of the Union, Oxford, December 1945, and the Extraordinary Assembly, Cambridge, July 1946. Published by the Bureau of the Union at Kew Observatory, Richmond, Surrey.

With the example set by the parent union at its 1946 assembly, many of the International Union's associations have had meetings of their own executive committees and councils to put their post-war houses in order and to make plans for the next general assembly, which will be held in Oslo during August 19–28, 1948. Partly in anticipation of that assembly and partly to renew and extend interest in the work of the Union, a pamphlet describing its organisation and scientific activities and those of its constituent associations and commissions has just been published by the Union's Bureau (at present at Kew Observatory, Richmond, Surrey), where copies can be obtained.

THE SWEDISH DEEP-SEA EXPEDITION

By Prof. HANS PETTERSSON

THE Swedish Deep-Sea Expedition left Göteborg on July 4 on board the 1,400-ton motor-schooner *Albatross*, which had been specially fitted out for the purpose at the Lindholmen shipyard with air-conditioned laboratories and accommodation for the scientific staff, dark rooms, workshops, cold-storage room, electric winches, etc. The main purpose of the cruise, which is expected to last for fifteen months, is to investigate the deep ocean bed and its deposits by means of new methods developed in Sweden during the war years. The first part of the cruise, between Madeira and Panama, has now been completed. Some of the results are here briefly summarized.

A new and powerful echo-sounding equipment has been constructed for the *Albatross* by the Marine Instruments, Ltd., of London (formerly Henry Hughes and Sons, Ltd.), in order to get detailed and continuous records of the depth down to at least 7,500 metres. The records so far obtained go down to more than 6,000 metres and are very interesting. They prove that older views of the deep-sea bottom as a smooth, perfectly level surface, especially in the depressions, are radically wrong, at least as regards the part of the Atlantic Ocean which has been traversed. Such surfaces extending over several miles of our course were comparatively rare. Instead, the depth curve moves incessantly up or down, generally by gentle undulations but quite often rising or falling by distinct steps, 100 to more than 300 metres high and from less than one nautical mile to a few miles broad. The change in depth is sometimes so abrupt that the recorder cannot follow it, thus indicating nearly perpendicular walls hundreds of metres in height. One gets the impression of fault lines stretching more or less obliquely across the course. In other cases the slope is steadier, rising or falling by as much as 1 : 10, or even steeper. In certain places where the record tends to become confused, the bottom appears to be covered with small hills or hummocks, the record showing three or more convex lines, partly overlapping or intersecting at one point.

Crossing the central Atlantic Ridge, where the bottom was pronouncedly uneven and rich in steps or hummocks, its highest point found by us, quite close to the place where the Admiralty chart has the depth of 934 fathoms, in lat. 23° 10′ N., long. 45° 10′ W., has a minimum depth of only 786 fathoms or about 1,440 metres. Evidently a close net of echograms will be required for any detailed study of the morphology of the Atlantic bottom.

In the Caribbean Sea the depth curve along our course from Martinique to Panama was much steadier than in the open Atlantic, hummocks and steps in the curve were rare, and the depth remained constant to within a few fathoms over distances of 50–100 nautical miles or even more. It is interesting to note that bottom features similar to those of the Caribbean were found also between Algiers and the Tyrrhenian Sea by the Swedish Expedition to the Western Mediterranean on board the *Skagerak* in 1946.

This surprising unevenness of the deep Atlantic bottom proved a serious complication in our attempts to measure the thickness of the sediment carpet by the method developed by Prof. W. Weibull of Bofors, who accompanied the Expedition to Panama. By means of depth charges detonating at depths of 500, 2,500 or 4,500 metres below the surface, echoes are set up from the bottom itself as well as from reflecting surfaces deeper down in, or below, the sediment. Hydrophones of special construction suspended from the ship convert the sound-waves into electric impulses which are recorded on an oscillograph. Where the bottom profile is rough, diffuse reflexions obscure the oscillograms, whereas over a smooth bottom 'deep echoes' may be recorded. The values found (uncorrected for the somewhat higher velocity of sound in the sediment than in water) vary in the open Atlantic between 300 and nearly 2,500 metres.

In the Caribbean Sea, with its much smoother bottom, the oscillograms are very clear and give values which increase from east to west, from 250 metres to a maximum of 900 metres. The total depth of the reflecting surface, presumably the rocky floor beneath the sediment carpet, thus varies between 4,800 and 7,800 metres in the Atlantic and between 2,900 and 5,600 metres in the Caribbean Sea. In the western Mediterranean the maximum depth of a reflecting surface found in 1946 right in the centre of the Tyrrhenian Sea was 2,600 metres at a water depth of 3,600 metres. It will be of interest to continue these measurements also in the central Pacific Ocean, where we intend also to use depth charges exploding in the sediment itself.

Dr. B. Kullenberg, by means of his piston core-sampler, has taken some dozen cores from depths between 4,000 and 5,600 metres, most of them 10–15 metres long. Some of those taken in the open Atlantic in depths of 5,000 metres or more consist of red clay, which becomes very compact and takes on a deep chocolate-brown colour in the lower levels. Occasionally layers rich in Foraminifera are found intercalated in the red clay. Assuming the latter sediment to increase in thickness by 8 mm. in 1,000 years in the Atlantic Ocean, the lower strata of a core 15 metres long should have been deposited nearly two million years ago, or before the end of the Tertiary Age, when the deep ocean water is generally assumed to have been considerably warmer than during the Quaternary Age. This would seem to make it difficult to uphold an opinion prevalent among oceanographers, namely, that the lime-dissolving effect of the ice-cold Antarctic bottom current is the main or only agency capable of converting calcareous ooze into red clay.

In a 15-metre long core taken from a depth of nearly 4,900 metres at the centre of the Caribbean

Sea, the sediment has a strong greenish hue and displays an interesting stratification, with layers alternately rich and poor in calcareous shells. Dr. Fred Phleger, of the Woods Hole Oceanographic Institution, who was the guest of the Expedition between Martinique and Panama, sampled this core for Foraminifera and also collected plankton from the uppermost 1,000 metres of water by means of tow-nets of special construction.

Hydrographic soundings with temperature observations, also by means of the bathythermograph, and with water samples for chlorine and oxygen determinations were made across the Caribbean. Large-volume samples were taken from various depths, both in the open Atlantic and in the Caribbean, for measurements of uranium and radium. Such measurements have become of especial importance owing to the light they may shed on the ionium precipitation in the sea, which is supposed to be responsible for most of the radium present in deep-sea deposits.

The cores hitherto taken by the Expedition are being sent back to Sweden for analyses by various specialists. The *Albatross* now leaves for the Pacific part of the cruise, with the Galapagos Islands as the nearest goal.

OBITUARIES

Dr. S. H. Daukes, O.B.E.

By the death of Sidney Herbert Daukes, the medical profession has lost its leading authority on the modern medical museum. Daukes died on September 3 after a short illness. The son of the Rev. S. Whitfield Daukes, vicar of Holy Trinity, Beckenham, he was born on April 20, 1879. He was educated at Lancing College where he distinguished himself in various sports, and at Caius College, Cambridge. He took a second class in the Natural Science Tripos in 1900 and then studied medicine at the London Hospital. He qualified M.R.C.S., L.R.C.P. in 1905 and in the same year graduated M.B., B.Ch., Cambridge. After several years spent in hospital appointments and in general practice, he took his D.P.H. in 1912 and in 1913 the D.T.M. & H. By the outbreak of the First World War he had held a post as assistant school medical officer at Leeds and was chief assistant school medical officer for Norfolk.

In the War, Daukes served first as a special divisional sanitary officer in France. In the winter of 1917–18 the War Office established the School of Army Hygiene at Leeds, and Daukes was made responsible for its organisation and administration. He was mentioned in dispatches and received the O.B.E. in 1920. He wrote "A Manual of Sanitation Applied to Military Life", and he contributed the chapters on hygiene to the official medical history of the War.

After the War, Col. Andrew Balfour—later Sir Andrew Balfour—who was director of the Wellcome Bureau of Scientific Research, invited Daukes to become curator of the Museum of Tropical Medicine which had been established by Sir Henry Wellcome. Under Daukes' guidance its scope expanded, and in 1926 it became the Wellcome Museum of Medical Science, with Daukes as its first director.

Daukes held very strong views on the importance of visual education, and he organised his museum with this end in view. Each disease was dealt with as an entity, and in the bays devoted to it, the student could follow out the latest views on etiology, pathology, clinical features, treatment and prevention, each branch being illustrated by photographs, charts, pathological specimens, paintings and other visual representation which was calculated to impress the point in question on his mind. The Museum became an important teaching unit, and it was visited by many medical men from overseas, by practitioners proposing to specialize in tropical medicine, by medical students and by nurses and health visitors. In the years immediately preceding the Second World War, approximately 10,000 persons visited the Museum annually. The Ministry of Health included a demonstration of tropical diseases in the Wembley Exhibition in 1924, and this was largely planned by Daukes acting as organising secretary of the appropriate committee. Similar exhibits were sent to the Wembley Exhibition in 1925, to Antwerp in 1929 and to Paris in 1931. In 1928 Daukes graduated M.D. at Cambridge with a thesis on the medical museum. This thesis was later expanded and published as an important monograph. In 1940 Daukes was asked to take over, as a temporary measure, the administration of the Wellcome Historical Museum, the directorship of which had been held by Sir Henry Wellcome himself until his death.

Daukes was well known, under his pen name "Sidney Fairway", as a novelist with a wide popular appeal. His novels generally dealt with some aspect of medical life, his best known being "The Doctor's Defence" and "The Cuckoo in Harley Street". His last novel, "He Loved Freedom", was published a week or so before his death. His reminiscences will be published shortly with the title "A Pillar of Salt".

He married Emma, daughter of William Kempsell of Reigate, who died in 1944. In 1945, he married Ethel Maud, widow of E. J. T. Hoyle of Doncaster. He is survived by his widow and a son by the first marriage, Lieut.-Colonel Whitfield Daukes, R.A.M.C.

E. Ashworth Underwood

Prof. V. Ulehla

The many-sided Czechoslovak man of science, Vladimir Ulehla, died on July 3 at the age of fifty-eight. His father had taken a prominent part, years ago, in securing educational reforms in Moravia, and Vladimir's interest in science was further developed under Prof. B. Němec at Prague and at the University of Strasbourg. After 1919, Dr. Ulehla became professor of plant physiology and biology at the newly founded Masaryk University of Brno. His original contributions to science relate mainly to a study of protoplasmic movement in lower organisms, and the influence of various ions on cells and their protoplasm. The borderline of plant and animal life, and the infusoria especially, interested him and he made some physico-chemical investigations on plant colloids and on turgor. Ulehla also wrote two books in Czech of a philosophical nature, "Reflexions on Life" and "Beyond the Veil".

But Ulehla's special merit was his skill in interesting the general public of his country in science and culture. His first great opportunity came when he was the organiser of the remarkable Brno Contemporary Culture Exhibition of 1928. Moravia was then a centre of archæological interest on account of the recent discoveries concerning the prehistoric mammoth hunters. Thanks to Ulehla's organising ability the exhibition, which attracted international attention, gave a clear impression of Czechoslovakia's cultural and scientific progress during the first decade of its independence.

Next, Ulehla turned his attention to the production of educational and cultural films, and those depicting the colourful peasant life and scenery of south-east Moravia, where the Slovak inhabitants cling to their traditional dress and old customs and folklore, were particularly successful.

In addition to his duties at Brno University, Ulehla was from 1928 until 1939 scientific correspondent of the daily *Lidové Noviny*, and he resumed this work in 1945 when the journal reappeared as *Svobodné Noviny*.

J. G. F. D.

We regret to announce the following deaths:

Sir Albert Howard, C.I.E., Imperial economic botanist to the Government of India during 1905–24, director of the Institute of Plant Industry, Indore, during 1924–31, on October 20, aged seventy-four.

Dr. Ellsworth Huntington, formerly research associate in geography, Yale University, an authority on the effect of climate on human racial development, on October 16, aged seventy-one.

NEWS and VIEWS

Physiology at Charing Cross Hospital Medical School: Prof. William Burns

Prof. W. Burns, recently appointed to the chair of physiology at Charing Cross Hospital Medical School, London, is a graduate in science and medicine of the University of Aberdeen. He received his early education at the Mackie Academy, Stonehaven, whence he entered the University in 1930. Having graduated B.Sc. in 1932 and M.B., Ch.B. in 1935, he was appointed to an assistantship in the Department of Physiology, and in 1938 became senior lecturer. As a teacher and demonstrator, Burns brought to an orderliness of thought and expression the valuable gift of artistic skill in illustration. Prof. Burns' first interest in research work centred around the problems of carbohydrate and cardiac metabolism, but it soon became manifest that his chief interests lay in the realm of the biophysical. Until 1942 he was engaged in investigating activity in afferent nerves associated with the viscera. The results of this work were incorporated in a thesis for which he was awarded the D.Sc. degree.

Early in 1942, Prof. Burns' biophysical and technical interests suggested a potential usefulness in the war effort, and in that year he was called to the Admiralty. After a period of service at the Admiralty research laboratory, he was appointed physiologist on the staff of the headquarters of the Royal Naval Scientific Service and latterly was placed in charge of the Royal Naval Physiological Laboratory. During the period of his war service, he was engaged on various problems such as the application of acoustics, the habitability of submarines, operational considerations affecting special equipment in warships, etc. In the latter years of his Admiralty service, he was also responsible for liaison between the Royal Naval Scientific Service headquarters and the activities of the Royal Naval Personnel Research Committee of the Medical Research Council, in which the latter is associated with the Admiralty in dealing with problems involving the relationship of man to the various duties and types of environments imposed by the requirements of the Navy.

Walter Holbrook Gaskell (1847–1914)

One hundred years ago, on November 1, 1847, Walter Holbrook Gaskell was born at Naples. Gaskell was a physiologist to whom medicine continues to owe a deep and lasting debt. He was a mathematician by training, and on Michael Foster's advice he went in 1874 to Leipzig to Ludwig's laboratory, in those days the most important centre of physiological research in Europe. On his return he took up physiology as a career, being appointed lecturer at Cambridge in 1883. Gaskell laid the secure foundation for our knowledge of the pathology of the heart and of the autonomic nervous system. In a series of ingenious and conclusive experiments he showed that the beat of the heart is due to automatic rhythmic contractions of the heart muscle and to the wave of excitation flowing from sinus venosus to bulbus arteriosus and from muscle fibre to muscle fibre. By his zigzag incisions of heart muscle he proved the continuity of the rhythmic wave. He introduced the terms and conceptions 'heart block', 'fibrillation', and 'gallop-rhythm' into the literature, and was one of the pioneers in the galvanometric investigation of the heart. In 1890, at the request of the Hyderabad Commission, he investigated the action of chloroform. His fascinating book "The Origin of Vertebrates" appeared in 1908. As a lecturer Gaskell was popular and inspiring, though he was not eloquent. A big man physically and intellectually, his strength and his weakness lay in his love of generalizations, which sometimes led him to victory and as often led him astray. He died on September 7, 1914, in his sixty-seventh year.

George Green, 1793–1841

As a mathematician, George Green is among the immortals; as a man he sank back almost at the moment of his death into the obscurity from which he had startlingly emerged. From a volume of studies published in 1946 as a tribute to George Sarton, Mr. Gwynedd Green, of University College, Nottingham, has separated a biography of the miller-scholar who graduated as fourth wrangler at the age of forty-four, nine years after the private publication of an incomparable masterpiece. Property is located, wills are transcribed, correspondence between Kelvin and Crelle is reproduced, and there are notes on every traceable name in Green's family tree and on all but eight of the fifty-two subscribers to the printing of the famous "Essay"; bibliographical information is thorough, but mention should surely have been made of the collected edition of Green's papers which was prepared by Ferrers for Caius in 1871 and reproduced photographically in Paris in 1903. The circumstances of Green's life both in Nottingham and at Cambridge have been investigated once for all from local sources with an industry beyond praise, and if a condescending patron and a resentful daughter are more vivid in the story than the central figure himself, this is because no contemporary portrait or character sketch has been found and the author does not attempt imaginary reconstructions. It is sad to learn from a note added in manuscript that the mill in which Green laboured and studied was reduced to a shell by fire in July last.

Department of Scientific and Industrial Research: Activities in Scotland

THE view has been held by many that great benefits could accrue from the establishment of branches of the existing stations of the Department of Scientific and Industrial Research, or of new laboratories, in different parts of Great Britain. By such developments, the work of these stations could be brought more intimately before the notice of industrialists, practising engineers and others, and it would be more convenient for them to obtain the greatest benefit from the researches in progress by the most effective method—that of direct consultation and discussion with the staffs concerned. There is also the important argument that the research establishments themselves would be able more readily to appreciate the needs of industrial concerns and authorities in different places.

Accordingly, the announcement recently made concerning the establishment in Scotland of the new Mechanical Engineering Research Station and of sub-stations for fuel, building and road research will receive wide approval. There is in Scotland, of course, a long and distinguished tradition of engineering activity of every description. In addition, there are schools of engineering science within its four universities and at various technical colleges. These schools have already established a high reputation for their teaching and for their original work; they are anxious to develop the research side of their function, and the closer contact afforded with the Department of Scientific and Industrial Research by the new developments will be helpful in this direction. Nor can it be denied that the Department itself will stand to gain from making its points of contact with all universities more numerous and more personal.

New Vegetable Research Station

THE first meeting of the governing body of the new Vegetable Research Station was held at the offices of the Ministry of Agriculture on October 8. Its incorporation as a company limited by guarantee and not having a share capital was decided on and an organising committee was set up to select suitable candidates for the post of director and to examine suitable sites for the Station; it is considered that an area of at least 300 acres would be necessary. The members of the governing body are Sir Edward Salisbury, Dr. W. G. Ogg, Prof. G. E. Blackman, Dr. H. V. Taylor, Mr. R. L. Scarlett, Dr. J. Barker, Prof. J. W. Munro, Prof. R. H. Stoughton, Prof. F. T. Brooks, Prof. T. Wallace, Prof. S. J. Watson, Prof. W. Brown, Dr. C. D. Darlington, Mr. E. H. Gardener, Mr. G. G. Hole, Mr. W. F. Swift, Mr. J. Laity, Mr. A. A. Clucas, Mr. David Lowe, Mr. J. Cracknell, Mr. F. A. Secrett and Mr. G. W. Giles.

Agriculture in the Caribbean

THE Anglo-American Caribbean Commission was set up in 1942 to encourage social and economic co-operation between the United States of America and its possessions and bases in the Caribbean, and the United Kingdom and the British Colonies in the same area. In 1945, the Governments of France and the Netherlands accepted an invitation to join this body, which has since become known as the Caribbean Commission. The committee set up by its Research Council to deal with problems connected with agriculture, nutrition, fisheries and forestry has circulated a number of crop inquiries to the various agricultural departments and is issuing a series of publications based on the replies. "Grain Crops in the Caribbean", the third in the series, is now available on request from the Caribbean Research Council, Caribbean Commission, Kent House, Port of Spain, Trinidad, B.W.I. For four hundred years the agricultural systems have been largely based on single-crop agriculture for the export market. The obvious dangers of this policy and the advantages of diverse cropping have been repeatedly pointed out, and the cessation of rice imports from Burma and India during the War forced attention on the necessity for producing more food for home consumption and the desirability of encouraging inter-Caribbean trade. With the exception of rice in the Guianas and maize in British Honduras and Jamaica, both acreage and production of grain crops are normally very small. Methods of cultivation are primitive, manures are rarely used and losses are heavy owing to inadequate storage facilities. The general conclusion from the inquiry, however, is that though greater attention to fundamental research is of the utmost importance, the introduction of machinery and the application of existing knowledge could immediately bring about a substantial increase in grain production without reducing the acreage devoted to export crops.

A Central Library of the World

A PROJECT for a Central Library of the World, drawn up during the German occupation of France, with the dual objects of providing more effectively for the preservation of the documents on which human culture rests and making their utilization easier and more widespread, is of interest in relation to the programme of work now contemplated by the United Nations Educational, Scientific and Cultural Organisation, which already includes a library organisation. Of the seven stages in which it was visualized the project would be achieved, the first, that of bringing together in France a limited number of initiators, both French and foreigners resident in France, had been realized; and a second, that of formulating a concrete project and inviting the collaboration of a number of well-known French personalities, was in progress when this pamphlet was issued by the French Association for the Study of Bibliographic Questions (7 rue des St.-Pères, Paris 7), as was the fourth stage of inviting foreign co-operation. The further stages include the formation of an international committee and, after study of the problem by that committee, an international convention to set up the appropriate organisation, appoint the members and to decide on the official language to be used.

The preliminary scheme summarized in this pamphlet contemplates the establishment of the organisation, to be called the Bibliothèque Centrale du Monde, by a statute guaranteeing the absolute inviolability of the headquarters of the Organisation, which is to be regarded as a world reserve; the territory where it is located should belong to no nation. The organisation would be directed by a supreme council, and administered by an administrative council. Its director would be provided with a general secretariat and would also be responsible for the administrative, principal and auxiliary services. Besides ordinary members of council, there would be from three to ten times as many corresponding members. The supreme council would function largely through two permanent commissions, one of which would be responsible for the study of projects. The chief services contemplated include the deposition and distribution of documents, and diffusion of information. In particular, it is suggested that the organisation should provide at its central depot a universal primary bibliography, and should endeavour to secure the creation of a universal copyright system. It seems that with the establishment of the United Nations Educational, Scientific and Cultural Organisation, the proposals should, in the first instance, be considered by that body, presumably at the instance of one or other of the national delegations.

Literature of Spectrochemical Analysis

THE American Society for Testing Materials, through its Committee on Spectrographic Analysis, has sponsored the publication of two indexes on the literature of spectrochemical analysis. The first, issued in 1940, covered the years 1920–39 and contained 1,467 references and a detailed subject index. The second, "Index to the Literature on Spectrochemical Analysis. Part II, 1940–1945", issued in January of this year, gives references to 1,044 publications on spectrochemical analysis that have appeared during the years 1940–45 inclusive. In addition, there are thirty-six references, for the years 1938 and 1939, that were omitted from the earlier Index. The references are arranged in chronological order, and for each year the material is listed in alphabetical order according to the authors. English titles are given for all the papers, but foreign book titles are left untranslated. In the earlier Index abstracts were not given but only references to the published abstracts of the papers. Because of the widely scattered nature of the literature, and because many libraries probably lack complete sets of foreign periodicals for the war years, a brief abstract is provided, in Part II, for every spectrochemical publication listed. In most cases the abstracts are quoted verbatim from *Chemical Abstracts*, but where necessary, by consulting other abstracting journals and the original articles, a more suitable abstract has been compiled. This painstaking and intensive work, both of maintaining and compiling the Index, has been done under the direction of B. F. Scribner and W. F. Meggers, of the National Bureau of Standards, Washington. A helpful, detailed subject index, which covers the content rather than the titles of the several papers, completes the Index.

It is somewhat surprising that in spite of war-time restrictions on publication and the difficulties of access to foreign journals so much work has been done in the field of spectrochemical analysis during the War. The choice of spectrochemical methods in preference to others can only be attributed to the simplicity, speed, sensitivity and economy of these methods—all vital factors in war-time applications. With the return of industrial competition, these methods should prove equally valuable, and all spectrographers will find both Part II and the earlier Index indispensable as reference handbooks. The Index is clearly printed and bound in a paper cover, though for reference purposes in the laboratory it would have been preferable to have had a much heavier binding. Abbreviations are used extensively, and although no explanatory list is provided, no real difficulty will be experienced in understanding the text. The addition of a list of the full titles and addresses of periodicals to which reference is made would perhaps be an improvement. Copies of the Index can be obtained from A.S.T.M. Headquarters, 1916 Race Street, Philadelphia 3, Pasadena.

Nature Lover: The Magazine of the Countryside

THE recent publication of volume 4, No. 1 of *Nature Lover*, the magazine of the countryside, marks the revival of a much-needed popular journal which deals with the natural history and archæology of the British countryside. The greatest merit of the journal is that it chooses good, representative subject-matter which is fairly easily available, thus bringing these rural sciences within the reach of everyman. The present number contains short, readable articles on the "Unity of Nature" by C. H. Warren, "Secretive Badgers" by B. M. Nicholas, "British Fritillary Butterflies" by L. H. Newman, "Jimmy the Lizard" by Frances Pitt, "The Numbers of Animals" by Brian Vesey-Fitzgerald, "Water Problems of Fishes" by Chapman Pincher, "Some Strange Plant Habits" by Wolseley Banks, "Bird-watching on an East Coast Estuary" by R. H. Harrison, "Lavenham, Suffolk" by Geoffrey Morgan. Among these authors are some of Britain's best natural history writers, and some of the articles are illustrated by good photographs. This monthly journal can be strongly recommended to the general lay reader who is interested in country-life and natural history, and it should be encouraged in all our secondary schools, for its method of presentation is bound to stimulate interest. Subscription to *Nature Lover* is 16*s.* 6*d.* a year, including postage. Further information can be obtained from *Nature Lover*, Staples House, Cavendish Place, London, W.1.

U.S. National Academy of Sciences: Officers

ACCORDING to the annual statement, the present officers and members of the Council of the U.S. National Academy of Sciences are as follow: *President:* Prof. Alfred N. Richards, professor of pharmacology, University of Pennsylvania; *Vice-President:* Dean L. P. Eisenhart, Graduate School of Mathematics, Princeton University; *Foreign Secretary:* Prof. Detlev W. Bronk, Johnson professor of biophysics, University of Pennsylvania; *Home Secretary:* Dr. F. E. Wright, Geophysical Laboratory, Carnegie Institution, Washington; *Treasurer*: Dr. J. C. Hunsaker, Departments of Mechanical Engineering and Aeronautical Engineering, Massachusetts Institute of Technology. *Other Members of Council:* Dr. Walter R. Miles, Prof. W. Albert Noyes, jun., Prof. I. I. Rabi, Dr. W. M. Stanley, Dean John T. Tate and Dr. D. D. Van Slyke.

Rook Behaviour during Incubation

CLOSELY studying a rookery of eight nests during the incubation period, C. M. Ogilvie noticed that the hen birds applied themselves almost exclusively to incubation, while excursions were rare and very brief. (*British Birds*, **40**, No. 5; May, 1947.) Feeding and coition, when this occurred, took place upon the nest. The cock bird was responsible for feeding the hen, a duty which was performed with characteristic ceremony at irregular intervals; intrusions within the colony and invasions from without were combated by the male birds. Coition was more often promiscuous than between mated pairs, and took the form of an assault resisted by the hen and countered by other cocks.

University of Leeds: Appointments

THE following appointments in the University of Leeds have been announced: Mr. E. A. Vaughan, lecturer in the Department of Social Studies; Mr.

A. Johnson and Mr. L. G. Johnson, lecturers in the Departments of Economics and Extra-Mural Studies; Mr. Edward Broadhead, lecturer in zoology; Mr. J. D. Jenkins, lecturer in mining; Mr. H. J. King, lecturer in surveying; Dr. W. J. Allen and Dr. R. A. Kenney, lecturers in physiology; Mr. S. Dagley, lecturer in biochemistry; Mr. G. A. Nelson, lecturer in pharmacognosy.

The number of full-time students enrolled for the present session is 2,804; the number of ex-Service students at present in the University is approximately 1,200. The present total of students compares with 1,736 in 1938; the number of arts students has increased very markedly owing to the number of students returning to complete courses interrupted by national service, but apart from this the increase is fairly uniformly spread over all departments and faculties.

University of Sheffield: Appointments

THE following appointments have been made in the University of Sheffield: Dr. A. S. C. Lawrence, senior lecturer in physical chemistry; Dr. H. J. Tress, lecturer in glass technology; H. Graetzer, assistant lecturer in mathematics; G. H. Jowett, assistant lecturer in statistics in the Department of Mathematics; J. R. Beattie, assistant lecturer in physics; Douglas W. Riley, assistant lecturer in chemistry; H. J. Whiteley, assistant lecturer in pathology.

The following resignations have been announced: Dr. J. Sinclair, senior lecturer in mining, who has been appointed to the chair of mining at University College, Cardiff; Dr. F. Bielschowsky, cancer research worker in the Department of Pathology under the British Empire Cancer Campaign, who has been appointed director of cancer research for New Zealand.

The Night Sky in November

NEW moon occurs on Nov. 12d. 20h. 01m., U.T., and full moon on Nov. 28d. 08h. 45m. The following conjunctions with the moon take place: Nov. 6d. 03h., Mars 4° S.; Nov. 6d. 07h., Saturn 5° S.; Nov. 11d. 20h., Mercury 0·03° S.; Nov. 14d. 01h., Jupiter 2° N.; Nov. 14d. 10h., Venus 1° N. In addition to these conjunctions with the moon, the following conjunctions also take place: Nov. 9d. 14h., Venus in conjunction with Jupiter, Venus 0·9° S.; Nov. 11d. 18h., Mars in conjunction with Saturn, Mars 0·9° N. Mercury is in inferior conjunction on Nov. 5 and becomes a morning star later in the month, rising at 5h. 40 m., and 6h. at the middle and end of the month, respectively. Venus, an evening star, sets about 17h. throughout November and can be seen very low in the western sky. Mars, in the constellation of Leo, rises at 23h. 08m., 22h. 52m., and 22h. 25m., at the beginning, middle and end of the month respectively, and is close to Regulus towards the end of November. Jupiter sets in the early evening hours and is unobservable. Saturn rises at 23h. 38m., and 21h. 50m. at the beginning and end of the month, respectively, and can be seen in the constellation of Leo, fairly close to Mars. Occultations of stars brighter than magnitude 6 are as follows: Nov. 1d. 04h. 25·5m., υ Taur. (*D*); Nov. 1d. 05h. 08·9m., υ Taur. (*R*); Nov. 1d. 19h. 53·0m., 103 Taur. (*R*); Nov. 2d. 05h. 33·2m., 118 Taur. *f*. (*R*); Nov. 7d. 04h. 32·1m., 46 Leon. (*R*); Nov. 21d. 18h. 17·3m., τ Aqar. (*D*); Nov. 26d. 20h. 37·0m., σ Arie (*D*); Nov. 29d. 23h. 33·0m., 139 Taur. (*R*). *D* and *R* refer to disappearance and reappearance, respectively, and the latitude of Greenwich is assumed. There will be an annular eclipse of the sun on Nov. 12, invisible at Greenwich.

Announcements

PROF. ARTHUR HOLMES, regius professor of geology in the University of Edinburgh, has been elected a foreign member of the Royal Swedish Academy of Sciences.

THE Kelvin Medal Award Committee, consisting of the presidents of the Institutions of Civil Engineers, Mechanical Engineers, Electrical Engineers, Naval Architects, Mining and Metallurgy, Mining Engineers, and Engineers and Shipbuilders in Scotland, and the Iron and Steel Institute, has awarded the Kelvin Gold Medal for 1947 to Air Commodore F. G. Whittle, in recognition of the eminent services he has rendered to engineering science in those branches of engineering work with which Lord Kelvin was especially identified. The Medal is normally presented triennially, but the last award was made in 1938 to Sir J. J. Thomson.

DR. JOSEPH ARONSON, of the United States Bureau of Indian Affairs, has been awarded the Alvarenga Prize of 1947 of the College of Physicians of Philadelphia, in recognition of his studies on the evaluation of BCG vaccine in the control of tuberculosis.

AT the invitation of the British National Committee, the fourth plenary World Power Conference will be held in London in 1950.

THE International Union of Biological Sciences, with the financial support of the United Nations Educational, Scientific and Cultural Organisation, is arranging a symposium on the role of trace elements in plant physiology, to be held at Rothamsted Experimental Station during November 5–6, 1947. Seventeen research workers from Australia, Denmark, Finland, France, Great Britain, Netherlands, Norway, Sweden, Switzerland and the United States have accepted invitations to attend. The report on this symposium will be published by the International Union.

THE Linnean Society of London, in conjunction with the Systematics Association, is organising a course of twelve weekly lectures on the "Principles and Methods of Taxonomy". Lectures will be given in the rooms of the Linnean Society on Wednesdays at 5.30 p.m., the first lecture being on October 29. Leading plant and animal taxonomists are contributing to the course, which is open to advanced students of biology. Further information can be obtained from the Assistant Secretary, Linnean Society of London, Burlington House, Piccadilly, London, W.1.

A FARADAY SOCIETY general discussion on "The Physical Chemistry of Process Metallurgy" will be held in the latter half of September 1948. It is intended that the discussion should be devoted to the thermodynamics and kinetics of the high-temperature reactions involved in smelting and refining, but excluding reactions which occur in mechanical working and heat treatment, and also electrochemical processes in aqueous solutions. Thermodynamics will include thermochemical, free energy and equilibrium studies, and kinetics will include both chemical reactions and diffusion processes. Prospective contributors should forward to the Secretary of the Society summaries of any papers they would like to submit not later than February 1.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications

Electron Microscope Studies of Normal and Malignant Tissues of High- and Low-Breast-Cancer Strains of Mice

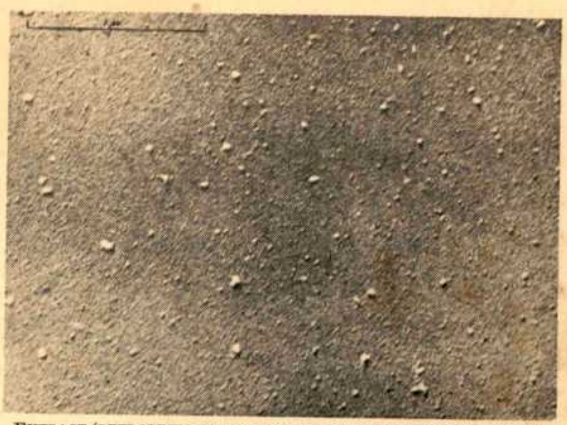
MAMMARY cancer in high-breast-cancer strains of mice has been shown by Bittner[1] to be transmissible to the offspring through the milk of the mother, and furthermore he has claimed[2] that all the tissues except the liver of high-cancer strains contain the same tumour-inducing factor as is found in the milk.

Barnum, Ball, Bittner and Visscher[3] described some of the physical properties of the milk factor present in tissues of mice of high-cancer strains. They found that petroleum ether does not destroy the tumour-inducing properties of tissues derived from high-cancer strains. They also observed that these properties remain unchanged at *p*H values between 5·0 and 10·2. According to Bittner[4], and confirmed by one of us (Dmochowski), extraction of breast-tumour tissue with distilled water is more efficient than with saline.

In June 1946, experiments were undertaken in order to examine with the electron microscope normal and malignant tissues obtained from high- and low-cancer strains.

Extracts of normal and malignant tissues from mice of *C3H*, Strong *A*, and *R*3 high-cancer strains, as well as of *C*57 black and *CBA* (which in this laboratory is a low-cancer strain), were prepared in the following way. Dried tissues were treated with petroleum ether, extracted with distilled water, treated with trypsin for 30 min. at 37° C., and filtered through Berkefeld *N* candles. The following tissue extracts were made: lactating breasts and breast tumours of *C3H*, Strong *A* and *R*3 strains; lactating breasts of *C*57 and *CBA* strains; breast tumours induced in *C*57 and in *IF* low-cancer-strain mice by methylcholanthrene; and also 37*S* transplantable sarcoma of the Imperial Cancer Research Fund, and a sarcoma induced in *C*57 by methylcholanthrene. In each case extracts of the same concentration were made, starting from equal amounts of dried tissue. Usually several tumours or lactating breasts from several mice of each strain were minced together and desiccated in the usual way[5]. In a few cases breast tumours and lactating breasts, each derived from a single mouse, were also examined. All extracts for electron microscopy were further diluted with filtered distilled water to a strictly comparable concentration, micro-drops were placed on filmed specimen grids, and the drops were drained immediately with a strip of filter paper to bring about rapid drying. After shadowing with metallic gold, the suspensions were photographed.

Results. Extracts of lactating breast tissues and of breast tumour tissues of *C3H*, Strong *A* and *R*3 strains were found to contain approximately spherical particles about 200 A. in diameter (see photograph). Extracts of lactating breast tissues from mice of *C*57 and *CBA* low-cancer strains, extracts of breast tumours induced in *C*57 and *IF* low-cancer strains by methylcholanthrene, and extracts of 37*S* sarcoma, were found to be free from such particles. Our results showed, therefore, that particles of about 200 A. diameter were consistently present in breast tissues and tumours of high-cancer strains, and consistently absent from those of low-cancer strains.



EXTRACT (PETROLEUM ETHER, DISTILLED WATER, TRYPSIN, BERKEFELD *N* CANDLE) OF *C3H* HIGH-CANCER STRAIN LACTATING BREAST TISSUE. GOLD-SHADOWED ON COLLODION FILM

Concurrently, all extracts were inoculated into *C*57 × *R*3 hybrid mice, susceptible to the development of breast cancer. The results of these biological tests are awaited.

Since this letter was ready for publication, it has come to our notice that Graff, Moore, Stanley *et al.*[6] have examined the milk of a high- and a low-cancer strain of mice and report finding a "characteristic material of large particle size" from the milk of their high-cancer strain and its absence or low concentration in their low-cancer strain. The significance of the difference in size between the particles encountered in the two laboratories is not clear at present, nor is the relationship between these particles and the tumour-inducing factor.

Specimen Changes due to Electron Bombardment in the Electron Microscope

WE have recently observed changes in a number of substances, chiefly ionic crystals, when subject to intense electron bombardment in the electron microscope. While the results are not readily interpretable, they do suggest that the effects may not be entirely due to the heating effect of the electron bombardment. It is for this reason, as well as for recording a type of artefact that has hitherto received little attention in the literature, that we report them here.

Using a cathode-biased electron gun[1,2] on the electron microscope built in the University of Toronto in 1944[3], it has been possible to obtain current densities at the specimen of the order 1 amp. per cm.^{2}, with accelerating potentials of 40–50 kV. With specimens mounted on 100 A. 'Formvar' films, the following changes have been observed.

Sodium chloride, sodium chlorate, potassium bromide and potassium iodide. The crystals, originally opaque, became transparent under electron bombardment (Figs. 1, 2 and 3). A residue was left behind which we believe to be the contaminating material discussed by Stewart[4] and Watson[5]. In some cases (Fig. 4) a deposit was formed around the crystal during the above change, and occasionally this deposit would itself later become more transparent.

Silver chloride. Under bombardment these crystals became transparent and produced an extensive deposit around them of fine opaque particles. These particles under bombardment later coalesced into a series of 'veins' with tributaries.

Lead chloride. Following a suggestion from Dr. James Hillier, at the R.C.A. Laboratories, Princeton, N.J., we examined evaporated films of lead chloride. Under bombardment this material gathers into globules which move on the 'Formvar' film.

With both sodium chloride and silver chloride it has been observed on occasion that when a crystal is bombarded with electrons and becomes transparent, forming a deposit in its vicinity, other crystals within the deposit throw shadows. While at first sight it is tempting to attribute these changes solely to sublimation or melting of the crystals, there is evidence which makes this hypothesis doubtful. Hall[6] has determined the sublimation temperatures for the following substances *in vacuo*, the first temperature being for slow sublimation, the second for rapid sublimation : trinitro-*m*-cresol, 80° C., 90° C. ; anthracene, 105° C., 120° C. ; carbazole, 125° C., 130° C. ; anhydrous citric acid, 137° C. ; 150° C. melts, 150° C. boils. Hall has also examined the changes in the substances under bombardment in the electron microscope. Mounting them on 'Formvar' films and examining in our microscope, we concluded, in agreement with Hall, that specimen temperatures could be made as high as 150° C., but at this temperature the 'Formvar' films would begin to melt.

Calculations similar, though less detailed than those of Borries and Glaser[7], indicated that the temperature of the ionic crystals mentioned above would never be more than 10° C. in excess of the temperature of the supporting film. This implies that the temperature of the crystals is too low for sublimation at pressures of the order of 10^{-4} to 10^{-5} mm. of mercury.

To check this point sodium chloride crystals were mounted on a 'Formvar' film on a mesh and heated *in vacuo* outside the microscope. It was possible to melt the 'Formvar' film at the centres of the mesh openings without subliming the salt. The fact that the salt had not sublimated was established by shadow-casting the crystals before heating them and then examining the specimen in the electron microscope after heating it. There were crystals present for all the shadows present; yet after this it was possible to make some of these salt crystals disappear under electron bombardment without damaging the film.

In view of the difficulties of explaining these changes on a hypothesis of sublimation alone, we have considered that ionic migration may play a part in the change. Fig. 5 shows a crystal of sodium chloride at an intermediate state of the change. Had the process been sublimation, one would have expected those parts of the crystal more remote from the supporting film, and therefore at a higher temperature, to disappear first. The reverse seems to be the case, which is not unexpected if the phenomena is due to migration.

Fig. 5, incidentally, would seem to provide evidence in support of the theory of a mosaic texture of rock salt discussed by Ewald and Renninger[8]. In addition to the interest in the fundamental nature of this phenomenon, there is the possibility of employing it in the study of crystal surfaces, either by examining the residual contaminating layers (Fig. 6) as a replica of the surface, or by shadow-casting the crystals to produce an all-metal replica and then removing the crystal from the replica by electron bombardment within the microscope.

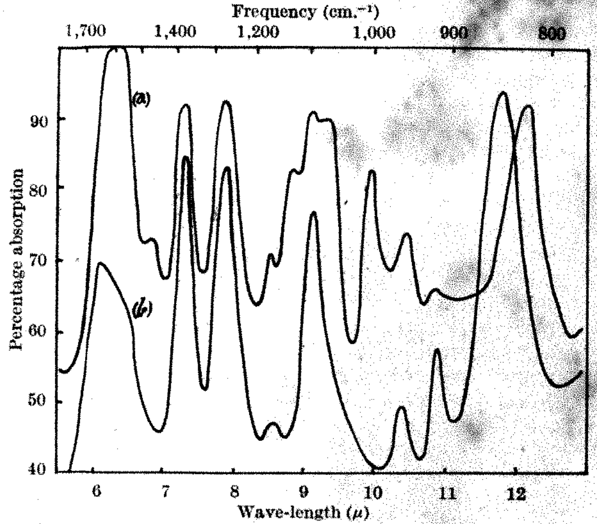
Use of Polarized Radiation in Infra-Red Analysis

In a recent communication in *Nature*, Elliott and Ambrose[1] have reported the use of a pile of selenium films for producing polarized infra-red radiation, and mentioned some interesting applications of their technique. They refer only to the previous work in this field of Ellis and Bath[2], who used a calcite prism, which restricts observations to the near region infra-red (up to 2·4 μ). The use of reflexion from a selenium mirror to produce completely polarized infra-red radiation over wave-lengths up to about 14 μ was discovered by Pfund[3] in 1906, and this method has been employed by several observers[4] in the examination of crystals of inorganic salts. We have for some time been using the Pfund reflexion technique very successfully in the study of oriented solids of organic materials. Until further details are available, it is not possible to decide whether a reflexion or a transmission technique is the more efficient with selenium, but it seems certain that the technique of producing, handling and transporting stout selenium mirrors is much easier than that required for delicate films a few microns thick.

Our results will be described in detail elsewhere, but it may be worth mentioning here that very significant differences have been observed in the spectra of thin oriented films of various polymers (for example, rubber, polythene, rubber hydrochloride and polyvinylidene chloride) for many of the bands between 6 μ and 15 μ, depending on whether the plane of polarization of the incident radiation is parallel or perpendicular to an axis along which orientation is occurring. We produced the orientation by stretching in the case of rubber and polythene, whereas for rubber hydrochloride and polyvinylidene chloride, it had already been produced by the rolling action used in making the film.

The orientation effect was checked by X-ray examination of the films and, as might be expected, the polarization effects were greatest in those cases where X-ray examination indicated a high degree of orientation. In certain cases, the interpretations of the changes in the absorption bands are quite clear. For example, the band at 6 μ in rubber arising from the stretching vibration of the C=C bond is intensified when the electric vector is parallel to the direction of stretching. Again, in polythene, the band at 6·9 μ due to the symmetrical deformation vibration of the hydrogens in the CH_2 groups is intensified where the electric vector is perpendicular to the axis of stretching. This is even more marked in the 13·9 μ band, recently shown[5] also to involve a deformation motion of the CH_2 group, and proves it to be perpendicular to the chain axis. The behaviour of the well-known hydrocarbon band at 7·3 μ (generally assigned to a symmetrical deformation vibration of the CH_3 group) appears to be anomalous and requires further investigation. As Elliott and Ambrose have remarked, the behaviour of many bands under polarized radiation may be a valuable guide in making assignments to particular modes of vibration in complex molecules for which a complete analysis of the spectrum is impracticable.

There is another aspect of the use of polarized infra-red radiation which does not yet seem to have been appreciated[6], namely, its use in conjunction with X-ray analysis to establish the orientation of a molecule in the unit cell of a crystal. Certain chemical bonds (for example, CH, OH, NH and C = C, C = O, C = N) give highly characteristic absorption bands in the infra-red; using polarization techniques, the actual orientation of such bonds can be established provided a molecule possesses in its spectrum a band which can be unequivocally assigned to a certain chemical bond or a definite vibration of a group, and thus the orientation of the whole molecule in the unit cell can be determined.



Spectrum of *p,p′* dibromodiphenyl ketone crystal with the electric vector (*a*) parallel to the *b*-axis, (*b*) perpendicular to that axis

We have recently had a good demonstration of this in the case of *p,p′* dibromodiphenyl ketone, the X-ray analysis of which is now being completed by Dr. Toussaint of the University of Liège. Dr. Toussaint required confirmation of his analysis, which placed the CO bond along the *b*-axis of the crystal. This we were able to provide, as shown in the accompanying figure, which gives the spectrum of the compound with the electric vector (*a*) parallel to the *b*-axis, (*b*) perpendicular to that axis. It will be observed that the CO band near 6 μ in case (*a*) shows 100 per cent absorption, whereas in case (*b*) it only reaches 70 per cent. The difference is much more striking than these figures indicate, because the crystal employed had to be very thick (about ten times that generally used for a CO band). The 70 per cent absorption in the perpendicular orientation is really a small residual effect due either to imperfection in the crystal or to incomplete alignment of the axis of polarization perpendicular to the *b*-axis of the crystal.

We are indebted to Dr. Toussaint for permission to quote his results before publication, and to Mr. Clews for help in carrying out X-ray examination of some of the polymer films.

Temperature Variation of the Second-Order Raman Spectrum of Crystals

INVESTIGATING at different temperatures the spectrum of second-order scattering of crystals of the alkali-halide salts, we have detected some new peculiarities in the intensity distributions. The region of small frequencies of the spectrum of second-order scattering depends far more strongly on the temperature than the region of large frequencies. The photographs and the microphotometrical curves of the spectrum of scattering of the rock-salt crystal obtained by us at 250° C. and 700° C., and reproduced in Figs. 1*a* and *b*, confirm this statement.

Figs. 1*a* and *b* show that the decrease of intensities observed at a low temperature (250° C.) in the region of frequencies from 60 cm.$^{-1}$ up to 200 cm.$^{-1}$ of the continuous spectrum (marked by an arrow) becomes scarcely noticeable at a high temperature (700° C.). The curve of intensity distribution rises considerably in this region, whereas the trend of the high-frequency part of the curve does not change significantly with temperature. Thus in the spectra of second-order scattering there are regions of frequencies which strongly depend on the temperature variation, as well as regions which depend considerably less on it.

The difference combinations of the frequencies are situated in the region of the continuous spectrum of scattering, which depends strongly on the temperature. Therefore we believe that the strong dependence on temperature of the region of small frequencies is due to the fact that the difference combination vibrations depend on the temperature in a different manner and far more strongly than the octave and sum combination frequencies, which lie chiefly in a part of the spectrum of scattering more removed from the Rayleigh line.

Fig. 2

This strong temperature-dependence of the difference frequencies can be explained in the following way. At the appearance of the Raman spectrum of the second order, the incident radiation of the frequency ν_0 (the exciting quantum) interacts simultaneously with two proper vibrations of the lattice with the frequencies ω_i and ω_k. Either a Stokes or an anti-Stokes radiation in the scattered light of the frequency ν arises, owing to the exchange of the energies between the light quantum and the vibrations of the lattice. The energy transitions also taking place in the crystal lattice during these processes and leading to the formation of the sum and difference frequencies in the Raman spectra of the second order are illustrated by the schemes given in Figs. 2*a* and *b*.

Consideration of these schemes explains why the temperature-dependence of the intensity of the difference and sum frequencies must be different. It is well known that the anti-Stokes lines in the Raman spectrum of the first order are far more sensitive to variations of temperature than the Stokes lines. The appearance of the anti-Stokes lines involves the existence in the crystal lattice (or in the molecule) of excited vibrational states, and therefore the intensity of these lines is proportional to exp $(-h\omega/kT)$.

For the sum of combinational lines of the Raman spectrum of the second order, the observed intensity relationships must be near those of the first-order Raman spectrum. The intensity change of the Stokes sum lines with the temperature must be comparatively small (although stronger than for the Stokes lines of the same frequency of the Raman spectrum of the first order). The anti-Stokes lines of the sum frequencies will depend strongly on the temperature (although somewhat otherwise than in the Raman spectrum of the first order).

The Stokes difference frequencies differ sharply as regards temperature-dependence from the Stokes sum frequencies of the Raman spectrum of the second order. Fig. 2*b* shows that, for the difference frequencies, the appearance even of the Stokes lines is bound up with the existence of excited states of the lattice. Therefore, for the difference frequencies, the character of the dependence on the temperature of the Stokes lines in the scattering spectrum will be determined by an analogous factor exp $(-h\omega_i/kT)$, which usually characterizes the temperature-dependence of the anti-Stokes lines only. Consequently, the intensity of the Stokes difference lines rises very sharply with the temperature.

The dependence on the temperature of the intensity of the anti-Stokes difference frequencies of the Raman spectrum of the second order will be somewhat stronger than that of the lines of the same frequency in the Raman spectrum of the first order.

These simple descriptive considerations are in good agreement in general with the results of theoretical calculations of the temperature-dependence of the frequencies of the second-order scattering spectra carried out for the first time by P. P. Pavinsky[1].

Thus our investigations of the scattering spectra of heated rock-salt are in good agreement with the considerations we have discussed above.

In the spectrum of scattering of heated rock-salt the strong continuous background is clearly seen, especially in the region of small frequencies (from the Rayleigh line up to 200 cm.$^{-1}$). This affords further experimental confirmation of the correctness of the fundamental concepts of the Born theory of the crystal lattice.

Crystal Structures of *para*-Dinitrobenzene and *para*-Nitraniline

IN view of the rather surprising distortions reported in the dimensions of the *para*-dinitrobenzene molecule[1], a redetermination of this structure was recently attempted in this laboratory. The results of our preliminary two-dimensional survey did not point to a completely symmetrical molecule, but indicated that either (*a*) the planes of the nitro-groups may be slightly inclined (about 5°) to the plane of the benzene ring, or (*b*) the nitrogen – oxygen distances within the nitro-groups may not be equal, but differ by about 0·05 A. We were unable to distinguish between these alternatives by two-dimensional X-ray methods. In the meantime, we have learned that a full three-dimensional analysis of this structure has been undertaken elsewhere, so we have not pursued the matter further. The final results will be awaited with interest.

In the course of this work a certain resemblance was noted between the crystal structures of *para*-dinitrobenzene and *para*-nitraniline. For the former structure the space-group is $P2_1/n$, with two molecules in a unit cell of dimensions

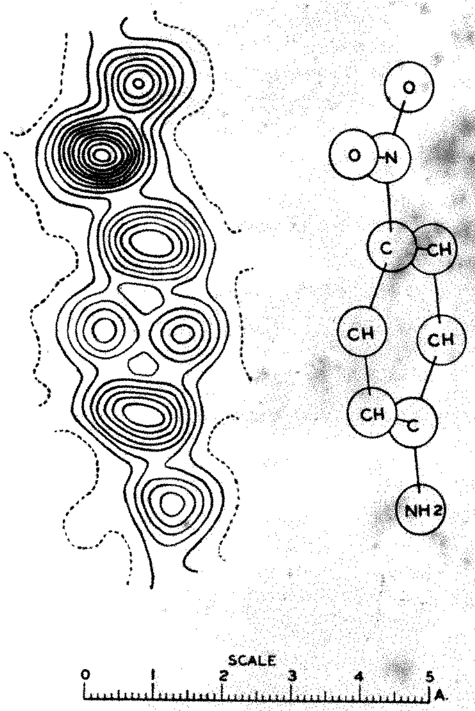
$$a = 11{\cdot}05 \text{ A.}, \ b = 5{\cdot}47 \text{ A.}, \ c = 5{\cdot}67 \text{ A.}, \ \beta = 92^\circ \ 18'.$$

The unit cell and space-group of *para*-nitraniline have already been determined by Prasad and Merchant[2], but if the space-group description is changed to $P2_1/n$, we obtain four molecules in a cell of dimensions

$$a = 12{\cdot}34 \text{ A.}, \ b = 6{\cdot}02 \text{ A.}, \ c = 8{\cdot}63 \text{ A.}, \ \beta = 91^\circ \ 40'.$$

The principal change is in the length of the *c*-axis, where the increase helps to accommodate the extra molecules. More detailed examination, however, shows that this apparent resemblance is somewhat misleading. In the *para*-dinitrobenzene structure there is a considerable concentration of atoms lying close to the $(10\bar{1})$ plane, whereas in *para*-nitraniline the greatest concentration is in the (101) plane. The actual inclination of the molecular plane to the (010) plane increases from 48° in *para*-dinitrobenzene to about 64° in *para*-nitraniline, although there is only a small increase in the length of the *b* axis.

The detailed structure of *para*-nitraniline has been elucidated by the method of trial and error, strong reflexions from the (800), $(50\bar{7})$ and $(70\bar{5})$ planes helping to define the molecular orientation. A refinement of the structure has been made by the double Fourier series method, and the electron density map for one molecule projected on the (010) plane is shown in the accompanying figure.



ELECTRON DENSITY MAP FOR *para*-NITRANILINE. CONTOURS AT UNIT ELECTRON DENSITY INTERVALS, THE ONE ELECTRON LINE BEING DOTTED

For this projection 110 terms in the (*h*0*l*) series were employed, and it gives good resolution for some of the atoms. The remaining co-ordinates may be determined from other similar projections; but further refinement is necessary before discussing the molecular dimensions in detail.

The preliminary parameters show that the distance between the amino-nitrogen atom and the oxygen atoms of the nitro-group of the molecule reproduced by the diagonal glide plane is 2·65 ± 0·05 A. This close approach shows that hydrogen bonding between the reactive groups of adjacent molecules is the main factor in stabilizing the structure.

Crystal Structure of *Para*-bromochlorobenzene

THE structure of *p*-bromochlorobenzene has been investigated by Hendricks[1], who found the space-group to be $P2_1/a$, and the number of molecules in the unit cell to be two. In an exactly repeating crystal structure, this would make it necessary for the molecule itself to have a centre of symmetry, which is, of course, impossible. Hendricks suggested that the symmetry of the crystal might be statistical, the halogen positions in the molecules composing the structure being filled at random by bromine or chlorine, or perhaps the two possible orientations of any given molecule, differing by 180°, were equally probable.

It was decided to re-examine the crystal, in order to see if any evidence of faults or irregularities in the structure, which might give rise to diffuse spectra, could be found.

The compound crystallizes from acetone in thin plates, only the *a* faces being developed. The crystals are very volatile, and oscillation and Weissenberg photographs were taken with the specimen inside a gelatine capsule. The unit cell is monoclinic, with dimensions $a = 15{\cdot}2$ A., $b = 5{\cdot}86$ A., $c = 4{\cdot}11$ A., $\beta = 113°$, and contains two molecules. The space-group was found to be $P2_1/a$, in agreement with the results of Hendricks. Since the space-group has four general positions, only a statistical symmetry is possible, with a centre of symmetry at the centre of the average molecule. There was no sign of any diffuseness of the spectra, and the appearance of the photographs is consistent with a completely random occupation of the halogen positions by bromine or chlorine.

Two-dimensional Fourier projections were made on the *ab* and *ac* planes. For the first approximation, only the positions of the mean halogen atoms were assumed, and these were enough to fix the phases of most of the spectra. The fact that the benzene ring appeared in the preliminary projections indicates that the type of assumption made as to the nature of the structure is probably correct.

In the final projections, shown in Figs. 1 and 2, the atoms of the ring are clearly defined, although there is some false detail still at the centre of the ring, which probably has no particular significance, and may be due to the difficulty of allowing for the rather large absorption in the crystals, because of their flat shape. The height of the peaks in the *para* positions corresponds to a group with a scattering power the mean of that of chlorine and bromine.

The values of the atomic parameters are given in the following table:

	x	y	z
Br,Cl	0·169	0·173	0·466
C_1	0·081	0·356	0·482
C_2	0·095	0·533	0·666
C_3	0·013	0·676	0·678

They differ somewhat from those suggested by Hendricks, but are closely similar to those given by Bezzi and Croatto[2] for *p*-dibromobenzene, which has essentially the same structure. The sides of the benzene ring, which is regular, have a length of 1·41 A., and the carbon-halogen distance is 1·77 ± 0·04 A., a value nearly the mean of the C—Cl and C—Br distances, 1·69 A. and 1·88 A. respectively, found by de Laszlo[3] in electron diffraction work on the dichloro- and dibromo-compounds. It is also less than the C—Br of 1·84 A. given by Bezzi and Croatto.

In conclusion, I wish to express my thanks to Prof. R. W. James for his interest in this work, and to the South African Council for Scientific and Industrial Research, to which I am indebted for a grant.

Purification of Renin by Means of Protein-Precipitating Agents

TRICHLOROACETIC acid has been used for denaturing and removing inert tissue proteins from kidney extracts containing renin[1]. It is also known that agents commonly used for removing proteins from solutions precipitate the proteins without causing denaturation in certain cases, so that the original protein may be regained. Thus trypsin and trypsinogen can be precipitated with trichloroacetic acid and the active enzymes regained[2]. In the same manner, crystalline egg albumin can be precipitated with metaphosphoric acid[3] and cathepsin by tungstic acid[4].

These investigations suggested to us the possibility of purifying renin by performing a fractional precipitation by means of such protein-precipitating agents. The blood pressure was determined by the capsular method[5].

(*A*) An extract of rabbit kidney purified by isoelectric precipitation of inactive proteins (*p*H 4·4) was prepared. 1·42 ml. corresponded to 1 gm. kidney. It gave an increase in blood pressure of 66 mm. mercury (1 gm. kidney per kgm. rabbit was used in all experiments) and contained 6·00 mgm. N (Kjeldahl) per gram of kidney.

(*B*) To 416 ml. of *A*, 10 per cent sulphosalicylic acid was added slowly at 0° to bring the extract to *p*H 3·0. After centrifugation, 447 ml. was obtained. 1 gm. kidney $\sim$ 1·52 ml. $\sim$ 4·05 mgm. N $\sim$ 68 mm. Hg.

(*C*) To 422 ml. of *B*, 7·5 ml. of 1·0 *M* sodium tungstate was added, followed by *N* hydrochloric acid to bring the extract to *p*H 2·1. The precipitate was isolated by centrifugation and dissolved in 30 ml. water with addition of sodium bicarbonate until neutral. Insoluble matter was discarded. Volume of centrifugate 38 ml. 1 gm. kidney $\sim$ 0·137 ml. $\sim$ 0·49 mgm. N $\sim$ 73 mm. Hg. After dialysis, 0·30 mgm. N.

The removal of inert proteins in *B* could be carried out with trichloroacetic acid, metaphosphoric acid and tungstic acid when suitable *p*H values were used, but sulphosalicylic acid was found to give the best yields. With this treatment most of the inactive proteins were removed. The tungstic acid precipitated at *p*H 2·1 all the active substance and left in solution almost all the nitrogen-containing substances of low molecular weight. In this manner it is very easy to obtain a concentrated purified solution of renin free from the bulk of tissue proteins and from low molecular impurities, and at the same time to avoid dialysis and concentration by evaporation.

These features, together with the great variability of the conditions for precipitation of proteins by such protein-precipitating agents, as compared with the usual methods (salt precipitation, alcohol precipitation, etc.) where it is the properties of the solvent which are changed, seem to make this a very convenient method which can be adapted to the fractional precipitation of a large number of proteins. Our preliminary experience suggests that the method might be of great value in the purification of biologically active proteins and enzymes.

This work was aided by a grant from Teknisk-kemisk Fond. Details will be published elsewhere.

Properties of the Fibrinokinase-Fibrinolysin System

IT was recently discovered that animal tissue cells contained an activator capable of transforming profibrinolysin into fibrinolysin[1]. The following properties of this enzyme system have now been found.

Two methods of investigating the action of the fibrinolysin were used. In the first method a 2–3 mm. thick layer of fibrin was prepared in a Petri dish (diameter, 10 cm.) from solutions of ox fibrinogen[2] (7 ml.), phosphate buffer (*N*/15, *p*H generally 6·5, 7 ml.) and ox thrombin[3] (50 units, obtained from Løvens kemiske Fabrik, Copenhagen). On these plates drops of the active solutions were placed. The plates were left standing 24 hours at 39°. In the second method the fibrinolysin was mixed with the fibrinogen solution before adding the thrombin, and the clot was made in a test-tube. The time in minutes for the fibrin to dissolve at 39° was measured. For the second method more potent solutions have to be used, but it permits a quantitative determination.

Fibrinokinase. The animal tissue retains its activating properties after grinding with sand and several washings with distilled water. No activator could be extracted from the tissue with the following solutions: phosphate buffer (*N*/15, *p*H 5·6–8·3), 0·9 per cent sodium chloride, acetic acid (1 per cent and 5 per cent), hydrochloric acid (0·01–0·1 *N*), ammonium hydroxide (0·01 *N*), sodium hydroxide (0·01 *N*) and glycerine (87 per cent) containing 0·5 per cent acetic acid.

The washed tissue pulp could be dehydrated with alcohol and acetone and dried with ether without destroying the activity. As a rule, a dry powder, prepared from pig's hearts, was used as activator. The tissue fibrinokinase is most stable at neutral and slightly acid reaction; at alkaline reaction it is destroyed slowly. Heating at 56° destroys it slowly, and at 70° immediately (5 min.).

The fibrinokinase activities of different tissues have been investigated, using various animal species as well as different organs. Small tissue fragments were placed on fibrin plates, and the diameter of the zone of dissolved area was used as a measure of the activity.

Tissues from calf embryo, pig and rabbit were usually found to be the most active, those from ox and rat were slightly less active, human and mouse only moderately active, while tissue from chicken and hen showed almost no activity. Of the organs, lung, heart and kidney were usually the most active. Pig's heart especially showed very high activity, while rabbit's heart was less active than other organs from rabbit. Liver and spleen were only slightly active. Stroma from erythrocytes (human) was very active.

Profibrinolysin. While the treatment (24h., 39°) of ox plasma or serum with fibrinokinase results in no activity because of a potent antifibrinolysin in the albumin fraction, the globulins prepared by 0·33 saturation with ammonium sulphate yield a very potent enzyme solution. The profibrinolysin contained in these globulin solutions is not completely precipitated by dialysis against tap water. It is rather stable against heating and changes of *p*H (stands heating to 56° for half an hour, but is slowly destroyed at 70°). Bovine profibrinolysin cannot be activated by streptokinase. Human profibrinolysin is activated by tissue fibrinokinase, but not to the same extent as with streptokinase.

Fibrinolysin. Bovine fibrinolysin is completely precipitated by dialysis against tap water, after which usually a considerable increase in activity is found. It is less stable than the profibrinolysin, being completely destroyed by heating to 70° in five minutes and slowly at 56°. It is thus possible to destroy the fibrinolysin without destruction of the profibrinolysin.

The activation may be carried out between *p*H 4 and *p*H 10 without any significant change in the activity after 24 hours incubation.

The *p*H optimum for the fibrinolysis is rather narrow, the activity being at its highest at about slightly acid reaction (*p*H 6·0–6·5).

The properties of the fibrinolysin formed seem identical with the properties of the fibrinolysin prepared by chloroform treatment.

β-Glucuronidase and Tissue Proliferation

IN a previous communication[1] it was shown that β-glucuronidase in liver or kidney rises following administration of toxic agents to mice, depending upon the organ or organs affected. It was suggested that a rise in this enzyme is associated with tissue repair rather than the damage itself. This view is confirmed by results for kidney following administration of mercuric nitrate or chloroform to male mice. In each case, the rise in the enzyme did not occur in the early stages of poisoning, but was seen when repair was well advanced.

Age	Treatment	Interval following treatment, days	G.U.*/gm. moist tissue			Histological findings
			Spleen	Liver	Kidney	
Adult	None	—	580	280	380	—
,,	2 gm. chloroform/kgm.	1	1079	939	194	Damage and repair in liver; necrosis without evidence of repair in kidney.

* One G.U. (glucuronidase unit) liberates 1 μgm. phenol from 0·015 *M* phenol glucuronide at 38° and *p*H 5·2 in 1 hr.

That there is a relation between tissue proliferation and β-glucuronidase is further borne out by the fact that high enzyme contents were found in the livers of adult mice following sub-total hepatectomy, and in the liver, spleen and kidneys of baby mice. These results, which are summarized in the table, may provide a simple explanation of the finding by Fishman and Fishman[2] that administration of œstrogens to ovariectomized mice causes a rise in uterine glucuronidase, and of the high figures for tumour glucuronidase recently described by Fishman[3].

Formation of Cellulose by *Acetobacter acetigenum*

BROWN[1] isolated from 'mother of vinegar' an organism which he designated *B. xylinum* because it formed a tough pellicle exhibiting the behaviour of cellulose. It is now known as *Acetobacter xylinum*. In more recent years, X-ray examination of the pellicle which it forms on media containing, in the several cases, glycerol and certain sugars and sugar alcohols, has shown the material to possess the same structure as vegetable cellulose (compare Hibbert and Barsha[2], Tarr and Hibbert[3], Barsha and Hibbert[4] and Khouvine[5]).

Acetobacter acetigenum, a related micro-organism, also forms a pellicle, the nature of which does not seem to have been studied. Recently, in the course of another investigation, Dr. D. Kulka working with one of us (T. K. W.) isolated a strain of *A. acetigenum* which was remarkable for the large amount of pellicle-material produced during its growth in a glucose yeast–water medium in the presence of calcium carbonate; in one experiment the dry weight of the pellicle accounted for 60 per cent of the weight of glucose initially in solution.

This strain grows well at 30° in certain natural and also synthetic media of *p*H value about 5, and it can utilize a large variety of substances as sources of energy. The pellicle from cultures on malt-wort gave the principal reactions of cellulose. Pellicles were collected from cultures grown on solutions of inorganic salts containing ammonium sulphate as the source of nitrogen, and, in the several cases, containing the following substances as the source of energy: glycol, glycerol, mannitol, arabinose, xylose, glucose, fructose, galactose, maltose, lactose, sucrose and soluble starch. The pentoses and the soluble starch afforded only slight pellicles; in the other cases the yield of material varied from 2 to 8 per cent on the carbon source. The pellicles from the pentoses and from starch were not examined in detail; chemical tests for cellulose, which were made with all the others, were positive. Further, on X-ray examination the purified pellicles gave the diagram of crystallites which is obtained on X-ray examination of cotton cellulose. When the membranes were dried under strain they showed preferred orientation. On hydrolysis with dilute sulphuric acid, the material gave glucose, characterized as the 2:4-dinitrophenylosazone, m.p. and mixed m.p. 264°. On acetolysis of pellicle matter with acetic anhydride, acetic acid and sulphuric acid, at room temperature for 15 days, penta-acetylglucose was obtained in 25 per cent yield.

The production of cellulose from ethylene glycol by *A. acetigenum* is of particular interest in view of a suggestion of Kluyver that in certain cases glycollic aldehyde may be polymerized to sugar by bacteria; compare also the suggestion of Hibbert and Perry[6] that glycol may be the precursor of carbohydrates in Nature. Wirth and Nord[7] detected pyruvic acid in cultures of a *Fusarium* species on pentoses. They assumed the other fission product of the pentose molecule to be glycollic aldehyde, but they did not succeed in isolating the latter. During this bacterial synthesis of cellulose from glycol, it was found possible to trap glycollic aldehyde and to characterize it as the 2 : 4-dinitrophenylosazone, m.p. above 310°. The bacterial conversion of glycerol to cellulose involved the formation of dihydroxyacetone. This was characterized as the phenylosazone, m.p. and mixed m.p. 132°, and also as the 2 : 4-dinitrophenylosazone, m.p. and mixed m.p. 284°.

We are indebted to Dr. H. Lipson, who gave us facilities for the preparation of X-ray photographs.

Detection of Acetic Acid in *A. niger* Growing on a Glucose Medium

MANY different views have been expressed concerning the chemical steps by which certain species of *Aspergillus* and of *Penicillium* convert glucose into citric acid. Some of the earlier hypotheses are now only of historical interest, and those modern views for which a reasonable amount of experimental support can be adduced have one feature in common, namely, the presumption that acetic acid is an essential intermediate. Up to the present time, however, the occurrence of this acid in cultures of *A. niger* on sugar does not appear to have been demonstrated. We have made many attempts to detect its presence in the metabolism solution, but without success, an outcome not entirely unexpected in view of the ease with which *A. niger* metabolizes acetic acid in the presence of sugar (compare Pfeffer[1]).

We succeeded, however, in demonstrating the presence of this acid in the mycelial mat of young cultures at the time when formation of citric acid had just commenced. Acetic acid was separated from the mycelium after the cells had been ruptured by grinding them with sand. Using three strains of *A. niger*, we obtained in each case only about 0·3 gm. of the acid from mycelial mats grown, in the separate experiments, on 5 litres of culture liquid. The latter consisted initially of a 12 per cent solution of glucose plus the requisite inorganic salts. A fourth strain of *A. niger* gave much higher yields, and on two occasions similar experiments afforded 2·35 gm. and 2·60 gm., respectively, of acetic acid. It was characterized as the silver salt and also as the *p*-nitrobenzyl ester, m.p. and mixed m.p. 78°.

Utilization of Citric Acid by some So-called Citrate-non-Utilizing Bacteria

KOSER[1] showed that all types of *B. coli* are capable of growth in a simple medium in which ammonium phosphate constitutes the source of nitrogen, and a fermentable carbohydrate such as glucose or lactose is the source of carbon; when citric acid is substituted for the carbohydrates, growth occurs only with the sub-group known as *Aerobacter-Cloacœ*. Growth in such medium, called Koser's test, has since become one of the basic criteria in differentiating the Koser-negative *E. coli* from the Koser-positive members of the *Escherichia* tribe.

Certain laboratory and clinical facts led us to surmise that in presence of nitrogen compounds, other than ammonium phosphate, citric acid might be utilized even by Koser-negative organisms. In order to test this hypothesis, a typical *E. coli* and a typical *E. aerobacter* were cultured in a variety of media to all of which citric acid (30 mgm. per 100 c.c.) was added. Citric acid was estimated by a modification of the pentabromacetone method of Pucher, Sherman and Vickery[2]; and a decrease in citric acid content of the culture flasks (as compared with a sterile medium control) was taken as the index of utilization of citric acid. Cultures and controls were incubated both at room and incubator temperatures for a period varying from 1 to 4 days.

It was first found that, despite good growth, *E. coli* does not utilize appreciable amounts of citric acid in a glucose-ammonium phosphate medium (0·1 per cent ammonium phosphate with 0·2 per cent glucose); thus the presence of a readily available source of carbon does not induce *E. coli* to utilize citric acid. Moreover, it was found that in this medium *E. aerobacter*, which utilizes citric acid in the absence of glucose, does not attack citric acid until practically all the glucose has been broken down. In a basic medium of 0·1 per cent asparagine in saline (*plus* citric acid) growth of *E. coli* is not much heavier than in the glucose-ammonium phosphate medium; however, it is found that in 48 hours, 15 per cent of the citric acid has been used by *E. coli* and 94 per cent by *E. aerobacter*. Identical figures were obtained when the asparagine content was raised to 1 per cent. On the other hand, in 2 per cent peptone water (B.D.H. peptone) 94 per cent of citric acid was used up by *E. coli* but only 60 per cent by *E. aerobacter*. Under similar conditions a strain of *Staphylococcus aureus* did not utilize citric acid.

It is thus clear that the failure of *E. coli* to grow in Koser's medium does not result from a fundamental incapacity of the organism to use citric acid either as a sole or additional source of carbon, since *E. coli* has been proved to be capable of utilizing citric acid under suitable conditions. It is thought that such conditions are provided by an appropriate hydrogen acceptor in the medium, and it is hoped to bring forward evidence in support of this hypothesis.

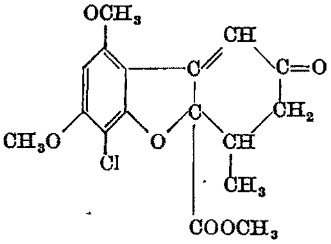
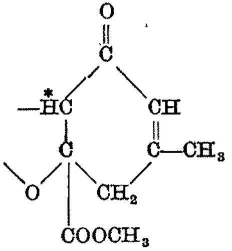
Identity of Griseofulvin and 'Curling-Factor'

WHEN *Penicillium janczewskii* is grown in liquid culture media a substance is produced which causes stunting, excessive branching and characteristic distortions in the germ tubes of *Botrytis allii* and other fungi[1]. The substance has been isolated and called 'curling-factor'[2]. When some preliminary observations[3] were made on the chemical and physical properties of curling-factor, the presence of chlorine was overlooked and a formula $C_{20}H_{20}O_8$ was proposed. We find that chlorine is present and that curling-factor is identical with griseofulvin $C_{17}H_{17}O_6Cl$, which was isolated several years ago by Oxford, Raistrick and Simonart[4] from *Penicillium griseofulvum* (for curling-factor found: C 58·4; H 4·9 per cent; mol. wt. 362; OCH_3 23·2; Cl 9·8 (micro) and 9·7 (macro) per cent; CH_3—(C) 4·9 per cent; calculated for $C_{17}H_{17}O_6Cl$: C 57·9; H 4·9 per cent; mol. wt. 352·7; OCH_3 26·4 (for three OCH_3); Cl 10·1; CH_3—(C) 4·3 (for one CH_3) per cent). The melting point (220°) of a sample of griseofulvin which was kindly supplied to us by Prof. Raistrick was not depressed by mixing with curling-factor (m.p. also 220°); and further, griseofulvin is identical with curling-factor in its biological properties[5].

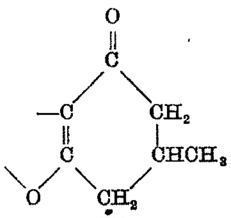
Most of the chemical reactions described by Oxford, Raistrick and Simonart have been carried out with curling-factor. A mono-oxime has been prepared; hydrolytic experiments have yielded griseofulvic acid, decarboxygriseofulvic acid and norgriseofulvic acid; and oxidation gave a chloro-hydroxy-dimethoxybenzoic acid.



I



II



III

The formula (I) for griseofulvin was suggested[4] tentatively as a working hypothesis and accounts for most of the reactions very well. We find, however, that decarboxygriseofulvic acid forms complexes which appear to be oxonium salts, and the complexes are not formed until the carboxyl group is removed. The structure III would be expected to yield oxonium complexes and is readily derived from II by the migration of two hydrogen atoms after hydrolysis and decarboxylation. Other evidence seems to be in favour of the slight modification of part of structure I shown by II. Formula II, unlike I, readily explains the production of orcinol on alkali fusion. In II one of the centres of optical activity indicated by * should undergo fairly ready racemization through enol formation. This might explain the easy production of an isomer of griseofulvin.

All the analyses were carried out by Drs. Weiler and Strauss with the exception of the chlorine estimations, for which we are indebted to Mr. J. Haslam, of I.C.I. Plastics Division.

A Fungistatic and Bacteriostatic Red Pigment Produced by a Strain of the *Penicillium nigricans-janczewskii* Series

Two distinct strains of the *Penicillium nigricans-janczewskii* series have been isolated from Wareham Heath soil[1]. One of these strains, regarded as typical of the species *Penicillium janczewskii* Zal., has been shown[2] to produce a substance causing marked abnormality of fungus growth; this substance has since been found to be identical with the previously known mould product griseofulvin[3]. The other strain, distinct from *P. janczewskii* and not definitely assignable to any of the described species within the *P. nigricans-janczewskii* series, has been shown to produce fungistatic and bacteriostatic culture filtrates on Raulin-Thom medium. A red pigment possessing antibacterial and fungistatic properties has now been isolated from such filtrates.

For the production of this pigment, cultures are incubated at 25° C. on shallow layers of medium for five days, when spore germination assays[4] show an activity of 16–32 B.A. units/ml. The culture filtrate is then extracted with chloroform and the extract evaporated to dryness. The residue is crystallized from ethanol, giving about 8 mgm. of crude red pigment per litre of culture filtrate.

By recrystallization from ethanol, glistening red needles are obtained. These begin to darken at 120° C. but do not melt at 380° C., nor is there any tendency for sublimation to occur at this temperature. The red pigment contains no nitrogen or halogen, and highly purified samples leave no ash on combustion. There are some indications of the presence of sulphur, but quantitative analysis has shown the amount present to be insignificant.

• Microanalyses carried out by Drs. Weiler and Strauss on material three times recrystallized from ethanol and dried to constant weight *in vacuo* give results in good agreement with an empirical formula $C_5H_4O_2$ (found: C = 61·8, 62·5, 62·7; H = 4·04, 4·50, 4·34 per cent; S = nil. $C_5H_4O_2$ requires C = 62·5; H = 4·20 per cent). A methoxyl determination indicated the presence of one methoxyl group per $C_{10}H_8O_4$, and this or some multiple of this unit would seem to be the most probable molecular formula. A Kuhn–Roth oxidation gave 8·6 per cent (C)—CH_3 and a Zerewitinoff determination 0·46 per cent active hydrogen. $C_{10}H_8O_4$ requires (C)—CH_3 = 7·8 per cent (for one); active hydrogen = 0·52 per cent (for one).

The red pigment is readily soluble in hot ethanol but sparingly soluble in the cold. It is slightly soluble in cold benzene, pyridine, glacial acetic acid and 1 : 4 dioxane, giving orange solutions. The orange dilute aqueous solution which is weakly acid turns yellow when made alkaline with caustic soda, and if the solution is now re-acidified it becomes almost colourless, the latter reaction being reversible. The pigment dissolves in concentrated sulphuric acid forming a green solution, and in concentrated nitric acid forming an orange solution which is decolorized on standing. With concentrated hydrochloric acid a deep crimson solution is produced which deposits violet needles on standing. These and other reactions indicate the formation of oxonium salts.

In nutrient broth at *p*H 7·0 the red pigment prevents growth of *Staphylococcus aureus* at a concentration of 50 µgm./ml. Germination of *Botrytis allii* conidia is prevented by 0·4 µgm./ml. of red pigment at *p*H 3·5. Aqueous solutions are extremely unstable; if solutions with an initial antifungal titre of 128 B.A. units/ml. are stored at *p*H 3·5 for 24 hours at 25° C., activity falls to 16 B.A. units/ml., and at *p*H 6·5 or above to less than 1 B.A. unit/ml.

We have some evidence that the mould also produces another antibiotic substance; further chemical and biological investigations are proceeding.

Formation of Uranium Hydride

THE formation of uranium hydride (UH_3) by the action of hydrogen on massive uranium metal between the temperatures 150° and 375° C. has been described by Burke[1].

We have found in further investigations that UH_3 would form at lower temperatures. The hydrogen used was tank hydrogen purified by passage over heated copper turnings and silica gel. 10 gm. of massive uranium metal were placed in tubes which were filled with 72 c.c. hydrogen at N.T.P. The tubes were large enough to ensure the presence of sufficient hydrogen to cause complete transformation. In all cases the reaction occurred only after an apparently quiescent period, which, especially at low temperature, lasted much longer than the reaction proper.

Temperatures (°C.)	Approximate time for complete formation of UH_3
250	2 hr.
200	2 hr.
150	5 hr.
125	12 hr.
100	24 hr.
75	60 hr.
50	~1 week
20	~2 weeks

Apparently uranium and hydrogen in contact are metastable even at room temperature.

Experiments were initiated to find whether the formation of uranium hydride might provide a means of separating from irradiated metal some, at least, of those fission products which form volatile hydrides, or belong to the rare gas group.

50 gm. of massive metal were irradiated for two weeks using 5 gm. radium–beryllium in paraffin. The metal was then heated in an evacuated system to 200° C. and hydrogen was slowly passed over the metal, after which the gas went over silica gel in a liquid air trap. After the metal had been completely transformed into hydride, the hydrogen was flushed out with argon and the silica gel examined for activity. None was found.

It thus seems that not even rare gases formed in fission are released during the transformation of massive uranium into uranium hydride.

Action of Per-Acids on the Iso-Octenes

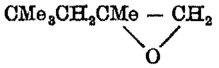
HICKINBOTTOM[1,2] finds unsaturated alcohols are formed in the treatment with per-acids of 2 : 4 : 4 trimethyl pentene-1 (I) and -2 (II) and also in the acid hydrolysis of the epoxide (IV) derived from the latter olefin. The object of this note is to show that these results do not, as Hickinbottom claims, throw any light on the double-bond shift observed in the air oxidation of some organic compounds, but can readily be accounted for by the formation of ionic intermediates. The action of the per-acids gives initially the epoxides (III and IV) by addition of oxygen to the double bond[3].

$CMe_3CH_2CMe = CH_2$

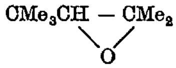
I

$CMe_3CH{=}CMe_2$

II



III



IV

$CMe_3CH_2\overset{\oplus}{C}MeCH_2OH$

V

$CMe_3CHOH.\overset{\oplus}{C}Me_2$

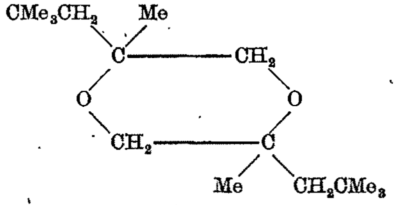
VI

The epoxides add a proton and the oxonium complexes formed react as the ions[4], V and VI. These ions are primary and secondary alcohols respectively since the C—O bond broken is such as to form the relatively stable isopropyl-type carbonium ion[5]. The subsequent reactions of these intermediate ions depend on the experimental conditions.

1. *Proton Loss.* V may lose a proton either from the methyl or methene group to give the two unsaturated alcohols observed by Hickinbottom, namely, $CMe_3.CH_2C(CH_2OH) = CH_2$ and $CMe_3CH = CMe.CH_2OH$. Only one unsaturated alcohol, as observed, is to be expected from VI, namely, $CMe_3.CHOH.CMe = CH_2$.

2. *Anion Addition.* Glycols result from the addition to V and VI of OH^-. In the acetic acid hydrolysis of IV, mentioned by Hickinbottom, the addition of OAc^- will give the 2 acetoxy 3-ol iso-octane.

3. *Condensation with Alcohol or Epoxide.* Ether-type compounds result from the interaction of, for example, VI with IV, yielding the neopentyl substituted 1 : 4 dioxan (VII), in general conformity with Hickinbottom's observation.



VII

Hickinbottom's work on the iso-octenes throws little light on the double-bond shift sometimes observed in the air oxidation of olefins[6]. The latter is accepted as due to the reaction of the intermediate free radical in its various resonance forms. Hickinbottom's observations, on the other hand, may be ascribed to the formation and subsequent reactions of an isopropyl-type carbonium ion.

[5] Evans, A. G., *Nature*, 158, 593 (1946).

[6] *In. al.*, Bergström, *Nature*, 156, 717 (1945).

DR. BREMNER's suggestions for the mechanism of the formation of unsaturated alcohols from epoxides must await further experimental work to determine the real value of his deductions. In one respect, Dr. Bremner's scheme is doubtful. It might reasonably be expected that the carbonium ions V and VI would lose a proton from the oxygen more readily than from a methyl group, to form carbonyl compounds with or without an alteration in the carbon skeleton.

It has been generally agreed that the free radical hypothesis of the peroxidation of olefins can provide an explanation of the formation of unsaturated hydroperoxides. It has the very serious defect of failing to account for the epoxides and dimeric material which are also formed during autoxidation. The rearrangement of the carbon skeleton which is observed when cyclic olefins undergo autoxidation in acetic acid is a further difficulty. Indeed, the free radical, hypothesis, so far from generally being accepted, is in need of extensive revision.

The object of the suggestion put forward in my note is to provide an alternative hypothesis which, moreover, has the merit of lending itself to experimental investigation.

Absolute Values of the Rates of Unimolecular Reactions

N. B. SLATER has recently discussed this subject[1]. Some time ago, I treated the same problem[2] not in terms of the normal modes of the molecule, but of the individual bonds where the kinetic energy is expressed as a mixed quadratic form and not as a pure sum of squares. The result, then, seems to permit of an easily visualized interpretation, namely, that the rate constant depends only on the force constant of the breaking bond, the energy required to rupture it, and on the two masses of the atoms adjacent to the breaking bond. It does not depend at all on the remainder of the molecule, which simply acts as a temperature bath. Thus the result is the same as for a diatomic molecule for which the temperature-independent constant is found to be *exactly* equal to its vibrational frequency.

Quantum treatment will slightly modify this[2] in so far as, especially with light hydrogen atoms, part of their mass is to be added to the mass of the heavier atom to which they are attached. Thus in a paraffin, a C—C end bond should crack less readily than any of the inner C—C bonds, as the end carbon atoms are more heavily loaded with hydrogen.

Reverting to the classical treatment, it is interesting to note that the temperature-independent factor of the rate constant for a large molecule is in general not equal to one of its proper frequencies, but is equal to the frequency of the imaginary diatomic molecule corresponding to its fissile bond.

I have verified in the case of a linear chain of four equal atoms and equal bonds for motions only along the line joining them, that Slater's result can also be expressed in this simple manner. The conjecture that the rule stated above holds in all cases seems very probable; I have not proved it generally but verified it in many cases.

[1] Slater, *Nature*, 159, 264 (1947).

[2] Pelzer, *Z. Elektrochem.*, 39, 608 (1933).

IF the internal kinetic and potential energies of the molecule are

$$T' = \tfrac{1}{2} \sum_{1}^{n} \sum a_{rs}\dot{q}_r\dot{q}_s \; , \; V = \tfrac{1}{2}\sum_{1}^{n} \sum b_{rs}q_rq_s, \qquad (1)$$

and if the oscillations of a particular co-ordinate q_1 (which is to break if it reaches a critical length q_0) are given by

$$q_1 = \sum_{1}^{n} \alpha_s\sqrt{\varepsilon_s} \cos (\lambda_s t + \varphi_s),$$

where $\lambda_s/2\pi$ is the frequency, and ε_s the energy, in the sth normal mode of vibration, then it can be shown that

$$\alpha^2 \equiv \Sigma\dot{\alpha}_s^2 = 2/b \ , \ \Sigma\alpha_s^2\lambda_s^2 = 2/a, \qquad (2)$$

where a, b denote the ratios of the determinants $|a_{rs}|$, $|b_{rs}|$ to the co-factors of a_{11}, b_{11} respectively.

Thus, in my previous expression[1] for the high-pressure unimolecular rate, namely,

$$K = \nu \exp(-E_0/kT), \qquad (3)$$

where

$$\nu = \sqrt{(\Sigma\alpha_s^2\lambda_s^2)}/2\pi\alpha \ , \ E_0 = q_0^2/\alpha^2, \qquad (4)$$

the frequency ν and dissociation energy E_0 are, by (2),

$$\nu = \sqrt{(b/a)}/2\pi \ , \ E_0 = \tfrac{1}{2}bq_0^2. \qquad (5)$$

The result (3), (5) can also be obtained by a generalization of Pelzer's earlier work[2] on chain molecules.

In the particular case where co-ordinate q_1 is the extension of a bond between two atoms of masses m_1,m_2, then

$$a = m_1m_2/(m_1 + m_2) \equiv m^*, \qquad (6)$$

which is the 'reduced mass' of m_1,m_2 for relative motion along their join. If also there are no cross-terms in V between q_1 and the other co-ordinates, so that

$$2V = b_{11}q_1^2 + \sum_2^n \Sigma b_{rs}q_rq_s, \qquad (7)$$

then

$$b = b_{11}. \qquad (8)$$

Hence in this case, by (5),

$$\nu = \sqrt{(b_{11}/m^*)}/2\pi \ , \ E_0 = \tfrac{1}{2}b_{11}q_0^2. \qquad (9)$$

This ν is the frequency of the "imaginary diatomic molecule corresponding to its fissile bond" (atoms m_1,m_2 with potential $\tfrac{1}{2}b_{11}q_1^2$). Thus Pelzer's conjecture is true when the potential energy is of the form (7); this includes the case[2] of a chain molecule with V a pure sum of squares. A gas of these "imaginary diatomic molecules" would, of course, dissociate at the unimolecular rate (3) only if the pressure were extremely high, but this does not impair the usefulness of Pelzer's conception.

A New Source of Taraxerol

IN the course of an investigation for alkaloids in *Litzea dealbata* (Lauraceæ) in this laboratory, it was noticed that from the alcoholic extract of the bark small crystals separated. Purification of these yielded a white product, m.p. 269–270° C., which gave a red-violet colour in the Liebermann–Burchardt test.

The melting point of this material and its two derivatives, the benzoyl and acetyl, together with the rotation and analysis of each, indicated that it was identical with the triterpene, taraxerol, isolated by Burrows and Simpson[1] in 1938 from the roots of *Taraxacum officinale*.

As the yield from this latter source is small and the purification from other triterpenes present tedious, little chemical work has been reported on the substance. The yield from *Litzea dealbata* being good and the purification simple, and there being, apparently, no other triterpenes present, it is intended to investigate some aspects of the chemistry of this substance.

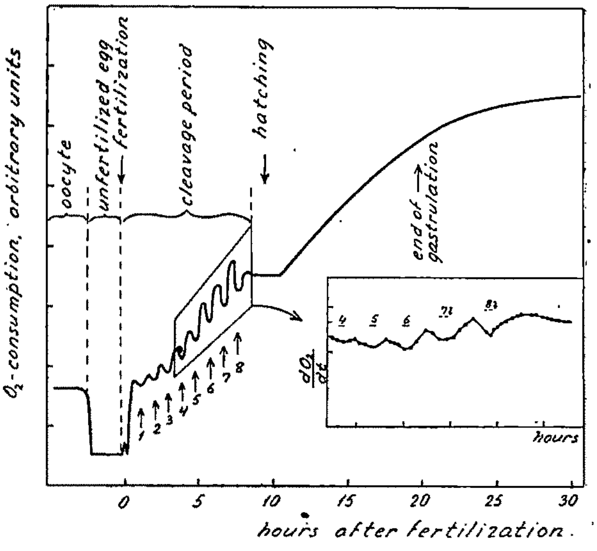
Respiration and Cell-Division in Eggs of the Sea Urchin, *Psammechinus miliaris*

As described in previous publications[1,2], we have found, by using modified Cartesian divers, that the frog's egg during cleavage respires rhythmically. The cleavage furrow invariably appears during a period of increasing respiration, the increase, however, being only slight, namely, 7–11 per cent. Single frog's eggs were used for these experiments, and the first three cleavages only were studied.

The experiments have now been continued and extended to eggs of the sea urchin, *Psammechinus miliaris*. The technique employed was a further development of that described[1], but about 200–300 eggs, dividing synchronously, were used for each experiment. The eggs were studied (at 16° C.) during the eight–nine hour period from just before the first cleavage until hatching; at least eight successive cleavages occur in this period. According to Lindahl[3], the well-known increase in respiration intensity during this period follows an S-shaped curve. I have found, however, that Lindahl's curve has waves superimposed on it, one wave accompanying each mitosis. The cleavage furrow always appeared when the respiration intensity was low. The respiratory variations accompanying the later cleavages were definitely more pronounced than those accompanying the first cleavages, the latter being of the same order as in the frog egg. According to Lindahl, hatching occurs during a period of almost constant respiration, and I have found the respiratory waves to disappear altogether just before hatching, which itself is followed by no change at all in respiration intensity.

In the accompanying figure, the inset small graph describes one experiment on about 300 sea urchin



eggs, dividing synchronously. The periods during which the cleavage furrow appears in all eggs are indicated by horizontal lines, and the cleavage numbers are given above the corresponding lines. Only cleavages 7 and 8 could not be actually observed in the microscope.

In the main figure the first part of the curve represents the respiration intensity of the oocyte and the unfertilized egg according to Lindahl and Holter[4]. As first described by Warburg[5] and afterwards confirmed by many others, an increase in respiration intensity occurs just after fertilization. The part of the curve describing this increase is based on the results of Laser and Rothschild[6], Runnström[7] and others. During subsequent development, the respiration intensity increases according to Lindahl's curve, but the mitotic rhythm described is superimposed upon the *S*-shaped part of it. It should be emphasized that after hatching the mitotic activity of the germ is most probably very much reduced.

Thus, in the sea urchin egg as well as in the frog egg, the early cell divisions appear to be accompanied by distinct respiratory variations, the biochemical significance of which, however, remains to be elucidated. In developing anthers, Erickson[8] found the respiratory intensity to vary in rhythm with the mitoses.

Rearing of *Trombicula acuscutellaris* Walch

In a previous communication[1] some successful feeding experiments with the adults of *Trombicula acuscutellaris* Walch on the eggs, ovaries and adults of *Mansonia* (*Mansonioides*) *uniformis* (Theobald) (*Tæniorhynchus* (*M.*) *uniformis*) were described. Since then, further proof of the carnivorous habits of this species has been obtained and adults have been fed on freshly killed Collembola and psocids. They are unable, however, to trap living Collembola or psocids, and it is unlikely that in Nature such active insects would be utilized as food. But for the routine feeding of nymphs and adults in the laboratory, it has been found more convenient to use culicine eggs, and for this purpose the eggs of *Culex fatigans* Wied. have been very largely used. These eggs are eaten with great avidity, and an ovipositing adult is capable of eating fifty or more eggs in 24 hours. By way of contrast, it may be mentioned that an adult of *T. deliensis* Walch, which is less than half the size of *T. acuscutellaris*, rarely eats more than two to four eggs in 24 hours and has never been known to exceed a maximum of nine eggs in that time.

The ease with which engorged larvæ could be reared to the nymphal stage in excavated glass blocks containing damp cellulose wadding has been previously recorded[2]. It has been found just as easy to rear nymphs to the adult stage on a diet of culicine eggs using the same technique. Oviposition commences within 10–12 days of the emergence of the adults. The eggs, which vary in colour from orange to reddish-orange, are invariably hidden by the female at the time of oviposition. The cellulose wadding gives them the opportunity of doing this, and it has been found that oviposition ceases if the wadding is changed to filter paper or plaster of Paris as recommended by Michener[3].

The eggs, which hatch in 10–12 days, are picked out from the wadding in the glass blocks and placed on several thicknesses of wadding in specimen tubes measuring 2 in. × ½ in. The wadding is then soaked with water up to the eighth day, after which cotton wool is wrapped around the inside of the cork. This takes up any excess moisture and prevents the larval mites from being trapped in droplets of moisture condensing in the tube.

White mice have had to be used as hosts, although they occasionally die, possibly as a result of being attacked by the mites, particularly when the numbers found attacking them are relatively large. This species is, however, not known to transmit *R. orientalis*.

The mice are placed in a wire cage the dimensions of which are 3 in. × 1 in. × 1 in., with a ¼-in. mesh. If the cage is big enough for the mouse to move its front legs freely, wadding is packed in at the rear end so as to prevent this; otherwise the actively moving larval mites are vigorously brushed off the face and ears by the mouse. The cage is placed on a platform of wire mesh resting on a wire frame ¾ in. high, which in turn is placed in a circular glass dish 6 in. in diameter and 2 in. in depth.

The tube containing the larval mites is vigorously tapped so that all the mites are shaken to the bottom. The tube is then uncorked and the mites tapped out of the tube on to the head of the mouse. A glass cover is placed over the dish. The mouse is released from the cage about 17 hours later and placed in a fresh dish. In general, only about 20 per cent of engorged larvæ are recovered from the host. The majority of unengorged larvæ, owing to their extreme motility, are found running about the dish and glass cover on the second day and are discarded. From the second day onwards, a layer of cellulose wadding is placed in the dish and damped daily with 25 c.c. of water, the glass cover being removed after the first day. Engorged mites are found trapped in the damp wadding from the third to the seventh day, the largest number of mites being obtained on the fourth day. The mouse is fed on dry bread for the first four days and thereafter on damp bread.

Larval mites of *T. acuscutellaris* generally attach themselves to the inside of the ears, particularly the meatus, around the vibrissæ and to the upper and lower eyelids. The body of the host is only occasionally chosen as a site of attack.

This species has been reared to the fourth generation using this technique. A complete account of this investigation will be published elsewhere.

β- AND γ-RADIATION FROM U^{239} AND Np^{239}

By PROF. HILDING SLÄTIS

IN connexion with the discovery of the transuranic element $_{93}Np^{239}$, McMillan and Abelson[1] report 0·47 MeV. as the upper energy limit of the β-spectrum. The γ-radiation was found to be complex and the energy less than 0·3 MeV. Philipp, Riedhammer and Wiedemann[2,3] studied the β-spectrum of Np^{239} photographically by means of the semicircular method. They found ten internal conversion lines. Eight of them were interpreted as the *K*-, *L*- and *M*-lines of three nuclear γ-radiations of the energies 208, 226 and 276 keV., two lines as the *L*- and *M*-lines of a *K*α-radiation. The results are reproduced in the accompanying table. Later, Philipp and Riedhammer[4] reported that the β-spectrum is a single one and that the β-decay is connected also with a 500 keV. γ-radiation. Recently, Feather and Krishnan[5] investigated the radiation from U^{239} by absorption measurements. They found, in the main, a single β-spectrum and give the value 1·20 MeV. for the upper energy limit. A γ-radiation of 76 keV. energy and another of at least 300 keV. were also observed.

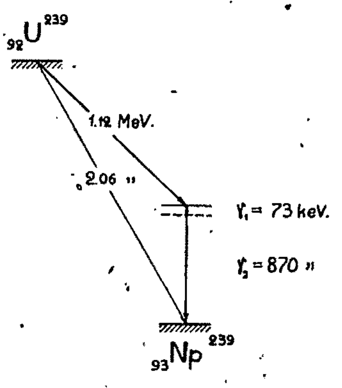

Fig. 2. NUCLEAR-LEVEL SCHEME FOR THE DISINTEGRATION OF U^{239}

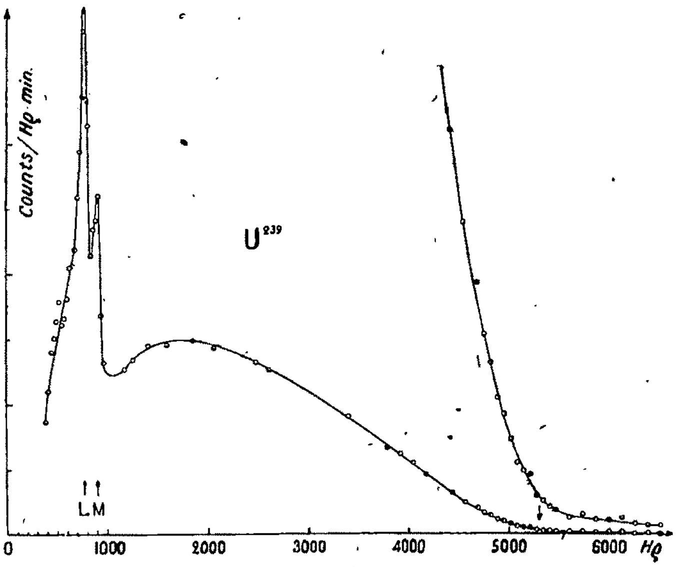

Fig. 1. β-SPECTRUM OF U^{239}

In the spring of this year I investigated the radiations from U^{239} and Np^{239}. Uranyl salicylaldehyde-*o*-phenylenediimine was irradiated with slow neutrons, and the U^{239} and Np^{239} formed were concentrated according to a technique developed by Melander[6]. Absorption measurements in lead showed that the γ-radiation from U^{239} consists of two components of energies 920 and 80 keV. Similarly, the γ-radiation from Np^{239} was found to consist of three components, 500, 200 and 51 keV.

The β-spectra were studied in a magnetic lens spectrograph constructed by K. Siegbahn[7]. The spectrum of U^{239} (Fig. 1) showed two internal conversion lines at 50·7 and 67·8 keV. They constitute *L*- and *M*-lines of a nuclear γ-radiation. The former gives the value 73·0 keV., and the latter 73·5 keV. for the energy of this γ-radiation. A Fermi analysis showed that the β-spectrum is double, with the upper energy limits 2·06 and 1·12 MeV. The difference, 0·94 MeV., corresponds to the higher value found by the absorp-

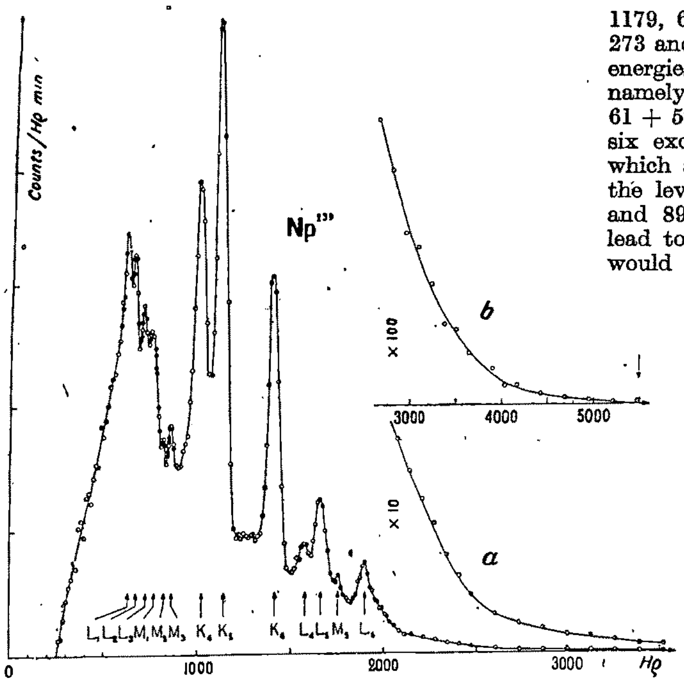

Fig. 3. β-SPECTRUM OF Np^{239}

(a) PART OF THE β-SPECTRUM, WHEN THE COUNTS ARE MULTIPLIED BY 10; (b) END OF THE β-SPECTRUM, WHEN THE COUNTS ARE MULTIPLIED BY 100

tion measurements, while the internal conversion line obviously answers to the lower one. These results lead to a disintegration scheme, in which the greatest part of the β-decay leads to an excited Np-nucleus, while a small part leads to the ground-state (Fig. 2).

In the β-spectrum of Np^{239} (Fig. 3) thirteen internal conversion lines were found. Seven of these (see table) are connected with the three nuclear γ-radiations 206, 227 and 275 keV. found by Philipp, Riedhammer and Wiedemann[3]. The six other lines are L- and M-conversion lines of three new γ-radiations of the energies 57, 61 and 67 keV. The L- and M-lines of the $K\alpha$-radiation in Pu^{239} were not found in the β-spectrum of Np^{239}, but appeared strongly in the spectrum of photo-electrons, released in a lead radiator. A Fermi analysis of the β-spectrum showed that it was fourfold with the upper energy limits 1179, 676, 403 and 288 keV. The differences, 503, 273 and 115 keV., correspond to the sum of pairs of energies computed from the internal conversion lines, namely, $503 \approx 275 + 227$, $273 = 206 + 67$, $115 \approx 61 + 57$. Therefore, the Pu^{239} nucleus seems to have six excited levels (Fig. 4), the differences between which are 275, 227, 206, 67, 61 and 57 keV. Thus the levels have the energies 275, 502, 708, 775, 836 and 893 keV. The β-decay of Np^{239} would chiefly lead to the 775 keV. level, while the other decays would lead to the levels 893, 502 keV. and the ground-state. Hence the γ-quanta would be emitted in cascade, 2, 4 and 6 in succession. An edge in the spectrum of the photo- and Compton-electrons released in lead gives evidence for a cross-over transition from the 775 keV. level to the ground-state in the Pu-nucleus.

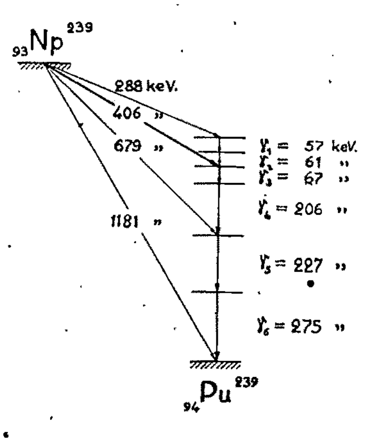

Fig. 4. NUCLEAR-LEVEL SCHEME FOR THE DISINTEGRATION OF Np^{239}

A detailed account of these investigations will be published in the near future[8].

I wish to express my thanks to the head of the Nobel Institute for Physics, Prof. Manne Siegbahn, by whose kind offices my stay in Stockholm was made possible. I am also indebted to the Nobel Foundation for fellowship grants made to me. My thanks are equally due to Dr. Lars Melander, who has carried out the chemical preparations, and to Dr. Kai Siegbahn for valuable discussions.

INFRA-RED SPECTRUM AND MOLECULAR STRUCTURE OF PHTHIOCERANE

By S. STÄLLBERG-STENHAGEN and PROF. E. STENHAGEN
Institute of Medical Chemistry, University of Uppsala
AND
N. SHEPPARD, DR. G. B. B. M. SUTHERLAND and A. WALSH
Laboratory of Colloid Science, Cambridge

THE properties of phthiocerane, the hydrocarbon derived from the wax alcohol phthiocerol[1,2] of the tubercle bacillus, for a pure specimen of which we are indebted to Prof. R. J. Anderson, Yale University, indicate a branched-chain structure[3], probably a long chain with a methyl side-chain near one end[4]. For comparison with phthiocerane, a series of hydrocarbons having a total of 34, 35 and 36 carbon atoms*, with a methyl side-chain in position 2-, 3-, 4-, or 5- from one end, have been synthesized at Uppsala, partly by the use of new synthetic methods[5]. The melting points of the synthetic hydrocarbons are plotted in Fig. 1 (the data for the n-hydrocarbons

---

* The analytical data for phthiocerol do not allow a decision between the formulæ $C_{34}H_{67}(OH)_2OCH_3$ and $C_{35}H_{69}(OH)_2OCH_3$ (cf. ref. 2). For the hydrocarbon, Stodola and Anderson favour the formula $C_{34}H_{70}$.

(1-methyl) are from Piper *et al.*[6]). The 2-methyl compounds melt at much higher temperatures than phthiocerane, and also differ in thermal behaviour and crystal structure (crystallize when pure only in tilted forms). The 3-, 4-, and 5-methyl substituted hydrocarbons, on the other hand, crystallize from acetone like phthiocerane with vertical chains, and also behave similarly on melting and solidification.

The long spacing of phthiocerane (46·3 A.) is the same as that of 4-methyltritriacontane (46·3 A.). Moreover, it is evident from Fig. 1 that the melting point of this hydrocarbon is close to that of phthiocerane. The *hk*0 reflexions observed for the synthetic hydrocarbons and phthiocerane agree closely with the corresponding strongest reflexions (that is, 110, 200, 210, 020, 310, 220) given by the vertical (*A*) form of normal chain hydrocarbons[7,8], both as regards spacings and relative intensities. The long spacing of 46·3 A. is nearly the same as that given by *n*-pentatriacontane (46·64 A., cf. ref. 8), which has two carbon atoms more in the long chain, and the main effect of the methyl side-chain in the branched-chain hydrocarbons is thus an expansion of the unit cell in the *c* direction. (The X-ray data on the synthetic hydrocarbons explain the previous interpretation of the X-ray diffraction pattern of an impure specimen of phthiocerane as being due to a normal chain[9].)

Although the data just given point to a 4-methyl substituted structure for phthiocerane, the physical properties of the hydrocarbons are such that other possibilities (mixtures) cannot be excluded on thermal and X-ray data alone (comparatively few orders of the long spacings are observed).

An infra-red investigation has therefore been carried out at Cambridge. The spectra of certain of the synthetic hydrocarbons with methyl groups in position 2-, 3-, 4- and 5- and of phthiocerane (a sample weighing about 8 mgm. was available) have been determined accurately between 700 and 1,400 cm.$^{-1}$ in solution in carbon disulphide. We find that the spectrum of phthiocerane is identical with that of 4-methyltritriacontane and 4-methyltetratriacontane, but differs markedly from those of the 2-, 3- and 5-methyl substituted compounds. The spectra are given in Fig. 2, with the exception of 2-methyltetratriacontane, which is not reproduced, since the 2-position for the methyl group is excluded on other grounds. It should be mentioned, however, that the spectrum of 2-methyltetratriacontane is quite different from any of the spectra in Fig. 2. It will be observed that the position of the methyl group has a very distinctive influence on the spectrum of these long-chain hydrocarbons, but that the spectrum is insensitive to a variation of one unit in the length of the main chain. The spectroscopic evidence for the correctness of a 4-methyl substituted structure for phthiocerane appears to be quite conclusive.

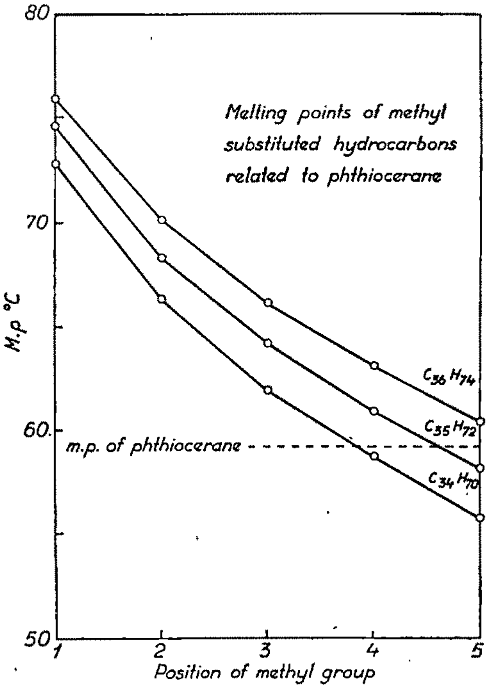

Fig. 1

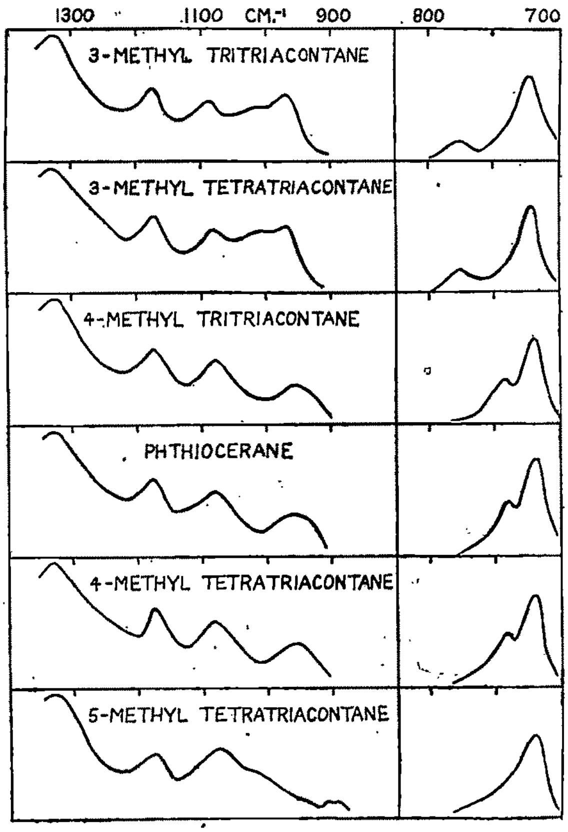

Fig. 2. INFRA-RED SPECTRA OF PHTHIOCERANE AND RELATED METHYL SUBSTITUTED HYDROCARBONS IN SOLUTION IN CARBON DISULPHIDE. 1,400–850 CM.$^{-1}$ (25 PER CENT SOLUTION); 800–700 CM.$^{-1}$ (6 PER CENT SOLUTION)

We should add, however, that apart from the empirical comparison of spectra, there is independent spectroscopic evidence that phthiocerane contains a methyl group in the 4-position. From extensive work done on hydrocarbons, at Oxford and Cambridge during the War, it is known[10] that long-chain paraffins having a methyl group in the 4-position always have a strong characteristic band at 740 cm.$^{-1}$. It will be noticed that such a band is present in phthiocerane; and the presence of this characteristic band provided strong, though not conclusive, evidence that phthiocerane has a methyl group in the 4-position. It is perhaps worth mentioning that the amount of material required for the final confirmatory run was just over 1·0 mgm. We have directed particular attention to these last points, since it seems quite probable that infra-red spectroscopy will have further interesting applications to problems of this type.

FURTHER OBSERVATIONS ON THE NUTRITIONAL REQUIREMENTS OF THE LARVA OF *AEDES ÆGYPTI* L.

By Dr. L. GOLBERG and Dr. B. De MEILLON

South African Institute for Medical Research, Johannesburg

THE mosquito larva, by virtue of its short life-cycle, as well as the ease and convenience with which its growth may be studied under aseptic conditions, lends itself to biochemical investigation. A survey of its nutritional requirements is of interest from the point of view of comparative biochemistry. The brief account which follows serves to illustrate some points of resemblance which the larva bears to the chick on one hand and to lower forms on the other.

'Folic acid.' We have previously reported[1] that Williams's 'folic acid' preparation, supplementing a medium composed of salts, vitamins and water-extracted yeast residue, can produce complete pupation and emergence of mosquito larvæ. In such media 'folic acid' may be replaced by synthetic *L. casei* liver factor (pteroylglutamic acid)[2] or by *L. casei* fermentation factor[3]. Attempts to substitute for the yeast residue a mixture of lipoids and a pure protein revealed that 'folic acid' still had some effect; but that pteroylglutamic acid was inactive, the larvæ dying in the fourth instar. There would thus appear to be some factor or factors in the yeast residue which are necessary adjuvants of pteroylglutamic acid in larval nutrition.

Of the substances tested for their ability to supplement pteroylglutamic acid in this way, the lactone of 4-pyridoxic acid proved effective and so to a lesser extent did the lactone of 5-pyridoxic acid. In general, the results bear a striking resemblance to those of Scott, Norris and Heuser[4] in the case of the chick. Even with pteroylglutamic acid and the lactone of 4-pyridoxic acid the rate of growth, as measured by the time spent in each stage of development, was still considerably slower than in the presence of yeast residue. For this reason studies on fat and protein requirements necessitated the use of yeast autolysate as a source of 'folic acid'.

Lipoid requirements. The fact that dietary lipoid is not required by the growing larva is in keeping with the mass of observations establishing the synthesis of fats by insects from dietary carbohydrate and protein[5]. In the absence of lipoids from the diet, however, most fully grown mosquito larvæ do not pupate. Of the pupæ formed, the majority fail to emerge as adults. Thus the effect of fat in the larval diet manifests itself principally during metamorphosis, and this specialized function is correlated with the need for special types of fat. The common saturated and unsaturated fatty acids and triglycerides are quite without effect. Active compounds capable of satisfying, at any rate to a considerable extent, the particular needs of the larva for pupation and emergence, include cholesterol and related sterols, but also highly purified lecithin in which sterols could not be detected. Some degree of activity is manifested by unrelated compounds such as β-carotene and kerasin. Many other similar compounds, including some sterols, steroid hormones and phospholipides show little or no activity.

In all these cases the lipoids were 'dried' on the solid (kaolin or powdered cellulose) from a suitable solvent. However, when lecithin was tested in solution in the liquid part of the medium, the lipoid effect could not be elicited. It is to be noted, too, that the best results were obtained by using a mixture of cholesterol, lecithin and cephalin (1 : 2 : 1) in the solid state.

Table 1. Steroids capable of bringing about pupation and emergence of mosquito larvæ

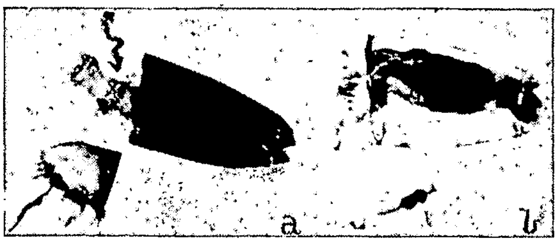
Active :	*Inactive :*
cholesterol and its esters	calciferol
sitosterol	all steroid hormones and related compounds of the pregnane, androstane, and œstrane series
Weakly active :	cholesteryl chloride
ergosterol	Δ^4-cholestenone* and its enol acetate*
stigmasterol (acetate)	α-7-hydroxy- and 7-ketocholesterols
coprosterol	$\Delta^{4,6}$-3-ketocholestadiene*
Active only in presence of yeast residue factor :	$\Delta^{3,5}$-7-ketocholestadiene*
zymosterol	3(β), 5, 6(*trans*)-trihydroxycholestane
β-cholestanol	*cis*- and *trans*-Δ^5-cholestene-3,4-diols and their diacetates
cholesterol dibromide	methyl Δ^5-3-acetoxy*bisnor*cholenate
7-dehydrocholesterol†	
Δ^4-3(β),6-dihydroxycholestene	
3(β)-hydroxy-6-ketocholestane	

* Growth-inhibitory. † Purity uncertain.

In the case of steroids it was found that apparently inert compounds could be made effective by the inclusion in the medium of a non-lipoid factor present in yeast residue but not in yeast autolysate. In the absence of this factor even the active sterols such as cholesterol do not produce optimum growth and survival of the larvæ. Bearing this fact in mind, a study may be made of the sterol derivatives capable of replacing cholesterol in the diet of the mosquito larva (Table 1). The results are to some extent in keeping with the findings of Fraenkel and Blewett[6] on other insect larvæ, and correspond remarkably closely with the observations of Cailleau[7] on the availability of sterols for *Trichomonas columbæ*. It is of interest to note that, of the cholesterol transformation products which Haslewood[8] has listed as likely to occur in normal cells during life, only two, Δ^4-3,6-dihydroxycholestene and 3-hydroxy-6-ketocholestane, are able to fulfil the larval need for lipoid. Moreover, both compounds are capable of exercising their effect only in the presence of the yeast factor to which we referred above.

Amino-acid requirements. The time taken by the first instar larva to reach the adult stage is an elastic quantity, ranging from 7·5 days to well over 30 days and depending almost entirely on the degree of adequacy of the medium. Nowhere was this elasticity more strikingly displayed than in experiments on the amino-acid requirements of the larva. With no added protein in the medium, growth does not proceed even to the second instar. Casein, particularly when in solution as sodium caseinate (1 per cent), could be used with lipoids and yeast autolysate to produce very good growth. Mixtures of nineteen and seventeen amino-acids were almost as effective as casein. The omission of dispensable amino-acids led to mixtures of from fourteen to eleven amino-acids, resulting in poor growth. Only a slight improvement could be brought about by varying the relative proportions of amino-acids present.

By omitting the amino-acids one at a time from the mixture of seventeen previously employed, the following were found to be indispensable for the growth of the larva: glycine, *l*-leucine, *dl*-*iso*leucine, *l*-histidine, *l*-arginine, *l*-lysine, *l*-tryptophane, *dl*-threonine, *dl*-phenylalanine, and *dl*-methionine. The status of *dl*-valine could not be determined while using yeast autolysate in the medium, since the autolysate was found to contain appreciable amounts of valine. 'Folic acid' could not be substituted for autolysate in amino-acid studies because no growth resulted, even when all other known growth requirements were satisfied.



SIPHON AND SADDLE OF (*a*) NORMALLY PIGMENTED FOURTH-STAGE LARVA; AND (*b*) UNPIGMENTED FOURTH-STAGE LARVA

The severity of the effect of deficiency of an essential amino-acid varied, but in the absence of each of several amino-acids no growth whatever could be observed. Perhaps the most interesting observation made in these studies was the effect of a medium deficient in phenylalanine or tyrosine. In the absence of added phenylalanine or tyrosine no growth takes place. With suboptimal amounts, the larvæ seem normal in every respect except that they appear to be wholly unpigmented. The accompanying photographs of the siphon and saddle of a normally pigmented fourth-stage larva and of the same area in an unpigmented larva serve to illustrate the ghost-like appearance of the latter. The pupæ, too, are lacking in pigment, but the adults which emerge are fully and characteristically pigmented. Two types of intermediate pigmentation were observed: in the first, black pigment begins to appear only in the fourth-instar larva; in the second, the use of substances analogous to tyrosine produced intermediate shades of pigmentation (Table 2). Both effects may be interpreted on the basis of the observation of Serra[9] that the diversity of colours of the melanins extracted from hairs of different hues results from the combination of varying proportions of melanoid pigment and protein. Lack of pigmentation does not appear to affect the rate of growth or survival.

TABLE 2. PIGMENTATION OF MOSQUITO LARVÆ IN A MEDIUM COMPOSED OF 0·5 PER CENT GELATINE, SUPPLEMENTARY AMINO-ACIDS (NO PHENYLALANINE OR TYROSINE) AND YEAST AUTOLYSATE

Compound tested	Concentration (gm. per l.)	Degree of pigmentation*
basal medium only	—	—
dl-phenylalanine	0·4	0
dl-phenylalanine	1·0	+ +
l-tyrosine	0·4	+ +
l-3-aminotyrosine	0·4	00
l-3,4-dihydroxyphenylalanine†	0·4	—
tyramine hydrochloride	0·4	0
dl-α-aminophenylacetic acid	0·4	0
p-aminophenylacetic acid	0·4	00 to +

* The significance of the symbols used is as follows:

—, white; no yellow pigment visible.
0, siphon and saddle clear yellow; no darkening.
00, siphon and saddle bright yellow; no darkening.
+, slight darkening of siphon and saddle.
+ +, siphon definitely darkened; saddle with a large clearly marked dark area dorsally.

† In this instance third-stage larvæ were examined. In all other cases fourth-stage pelts were used to assess the degree of pigmentation.

Despite the presence of large amounts of *dl*-methionine in the medium (up to 1·0 gm. per l.), the omission of the relatively small quantity of *l*-cystine customarily used (20 mgm. per l.) has an effect on the emergence of adult mosquitoes. The majority of the adults formed from the pupæ are found dead in the medium with only the upper half of the body projecting from the pupal case. Examination of the adults failed to reveal any obvious malformations. The same effect was occasionally observed in other amino-acid media, but was particularly prominent in the absence of added cystine. Cystine could be replaced by glutathione, but not by *dl*-homocystine.

The detailed findings, of which only the more salient features have been summarized above, will be published later, and full acknowledgment made to those who so kindly provided a number of the materials used in this work. Here we should like to thank Miss M. Currie and Mr. J. M. Thorp for technical assistance, and Mr. F. A. Brandt for the photographs.

BACTERIOLOGY OF WATER

DIFFERENT problems involving micro-organisms in fresh water and the importance of fundamental and co-operative research in this field were considered at a symposium on water bacteriology which was held at the University of Reading on July 10, as part of the programme of the annual general meeting of the Society for Applied Bacteriology.

Dr. F. Greenshields (Metropolitan Water Board) presented a paper concerned with water-supply biology, in which he pointed out that pollution of lowland rivers in Britain in recent decades with drainage from arable land, and with sewage and trade-waste effluents, is accelerating the biological maturation of downstream reservoirs. The production of dense crops of phytoplankton, leading to excessive clogging of the filters or to the production of objectionable tastes and odours, makes it increasingly difficult to make stored water available to the consumer at certain seasons. The application of algicides to established growths is of palliative value only, and utilization of other methods of scientific control is hampered by ignorance of fundamental knowledge of growth requirements of different organisms. The increasing spread of limnological knowledge through the medium of the Freshwater Biological Association, and the contributions of the Water Pollution Research Laboratory of the Department of Scientific and Industrial Research to the improvement in purification of sewage and trade wastes, should go far to achieve ultimate success in the effective control of algal growths.

Discussion of the paper was directed to the generally unsatisfactory procedure of chlorinating sewage effluents, which is not a feature in Great Britain, rather than endeavouring to obtain a more highly purified effluent; chlorination leaves the biochemical demand unsatisfied, and in the presence of gas works liquors may lead to production of cyanogen chloride —a substance of considerable toxicity to fish. It was considered that the construction of small-scale experimental reservoirs to follow up laboratory experiments is not so desirable as the use of reservoirs already established.

Difficulties which arise in assessing water quality from laboratory tests when coliform and pathogenic intestinal organisms develop outside their normal habitats were considered in a paper by Dr. E. Windle Taylor (Metropolitan Water Board) read by Mr. Burman. In the early days of the Second World War, it was found that efficient disinfection of water-mains after repair was sometimes difficult to achieve, and many investigations were undertaken to improve methods of repair and disinfection of mains. It was found that notwithstanding the greatest care that was taken in making a clean and hygienic repair and in the disinfection with chlorine, the raw jute yarn jointing material could itself be a source of subsequent contamination with micro-organisms. All types of coliform organisms, including *Bact. coli* type I, have been isolated, and it has been shown that some pathogenic intestinal organisms can also thrive on the yarn.

Laboratory experiments have confirmed the experience with samples collected in the distribution system that there are critical temperatures at which these coliform organisms can thrive. At the winter temperature of 4° C. and thereabouts, yarn is not a factor in the contamination of mains, but above 10° C. coliform organisms multiply actively in the yarn material. One lactose-fermenting organism having the reactions of *Bact. aerogenes,* except that it is capable of growing at 44° C., seems particularly associated with yarn and decaying wood, and on account of its frequent origin it has been christened the 'yarn' organism. Yarn in contact with water will form a breeding ground for pathogenic intestinal bacteria, and the ordinary chloramine residuals remaining in the water would have no disinfectant action. Researches have been undertaken into improving methods of chlorination of mains and into methods of sterilizing and treating joint-packing and also to find substitutes for it.

The paper led to spirited discussion on the specificity of the test involving the ability of *Bact. coli* type I to ferment lactose in MacConkey broth at 44° C., and the value of the test in view of the ability of the 'yarn' organism to carry out a similar reaction. It was suggested that if the indole test were used in conjunction with the 44° C. test it would be possible to distinguish between *coli* and *aerogenes* types growing at this temperature. In answer to a question, it was stated that jute was used as a packing material due to its cheapness and availability.

Some of the results obtained during a bacteriological survey of the Warwickshire Avon by the Water Pollution Research Laboratory in 1945–46 were given by Dr. C. L. Hannay and Irene L. Norton. In view of the fact that the bacterial flora of river water is pre-eminently Gram-negative, it was thought that interesting information might be obtained from counts in the river water of a Gram-positive organism the normal habitat of which is fæcal material. Consequently a study was made of fæcal streptococci isolated by means of a buffered glucose broth containing sodium azide. Results of the investigation, which included observations on the effect of sodium azide, showed that the proportion of streptococci isolated from river water which fermented mannitol was very similar to that found elsewhere for streptococci isolated from fæces. No streptococci with characteristics of either *Strep. lactis* or *Strep. bovis* were isolated, and it was considered that although the medium appeared to be specific for streptococci of Group *D*, ultimate specificity rests on serological grouping.

The paper evoked considerable discussion chiefly concerning the efficiency of the medium and method employed. It was considered by the authors that it is unlikely that at high dilution the streptococcal chains are disrupted, for replicate counts gave results in good agreement. Although no data had been obtained, it was considered that the survival-rates of various fæcal streptococci and coliform bacteria in river water are probably very different.

The seriousness of infection of imperfectly sealed cans of food due to contamination with cooling water of high bacterial count was discussed by Mr. T. E. Bashford (The Metal Box Co., Ltd.) in a paper entitled "Infected Cooling Water and its Effect on the Spoilage of Canned Foods". Due to methods of manufacture, it is not always possible to have cans with perfect seals, some minute channels being left unsealed. Laboratory experiments showed that the incidence of infection of the cans is greatly affected by the numbers of bacteria in the cooling water. As many canneries are situated in rural districts where the supply of water of low bacterial count is not always available, some method of sterilization should be employed, and tests had shown that chlorination is a suitable method. Dosages of chlorine to the cooling water allowing a chlorine residual of 1–2 p.p.m. and a contact time of 20–30 min., were found effective in reducing appreciably the numbers of infected cans, but subsequent contamination during distribution of faulty cans is always possible. It was suggested during discussion that more effective sealing compounds are required, and that possibly some rubber emulsion containing an antibiotic might be satisfactory in preventing contamination of the can and spoilage of the contents.

Dr. C. B. Taylor, in a paper entitled "Some Aspects of the Bacteriology of Lakes and Streams", pointed out the paradox that water bacteriology of the text-books is largely concerned with studies of organisms which have a normal habitat other than water, and that the Freshwater Biological Association is concerned primarily with fundamental studies of bacteria capable of multiplying in the waters of streams and lakes and in the deposits beneath. Preliminary work already carried out has shown that the distribution of bacteria in lake waters, estimated by plate counts, is largely dependent on water movements, which at times are extremely complex and vary rapidly with changing atmospheric conditions. In order to obtain a properly balanced consideration of 'water bacteriology' future work must involve studies of bacteria in (*a*) the water, (*b*) associated with the plankton, and (*c*) in the deposits. Work is in progress in connexion with the factors which limit growth of bacteria in lake waters, and it is hoped that the results will serve as an introduction to a more specialized study of the nutrition of water bacteria. As Algæ are the primary producers of organic matter in a large body of water, their association with bacteria in life and during decay is of considerable importance; present work, which has demonstrated that bacteria living on dying cells of the diatom *Asterionella* are unable to grow on common solid laboratory media, indicates the technical difficulties involved in such studies. Preliminary studies on lake muds has shown that in large bodies of water such autotrophic processes as involve nitrogen and sulphur oxidation are confined largely to the immediate surface layer of the deposits. In the discussion following the paper several speakers emphasized the need for developing work on the bacteriology of water along these lines.

C. B. TAYLOR

PRACTICAL TRAINING OF ELECTRICAL ENGINEERS

THE practical training of the professional electrical engineer is the subject of a report published recently by the Institution of Electrical Engineers*. The report, which is the work of a joint committee comprising representatives of the Institution, the Radio Industry Council and the British Electrical and Allied Manufacturers' Association, makes specific recommendations as to the character and duration of an ordered scheme of practical training, and reviews in some detail various considerations underlying its recommendations.

Where the young engineer has obtained his academic qualification by a full-time university course, the practical training should occupy two years and be termed a 'graduate apprenticeship'. Where, on the other hand, part-time technical education of appropriate standard is being pursued during the industrial apprenticeship, the duration of the practical training should be four years. This is termed a 'student apprenticeship'. Subdivision of the training period is made under three headings: basic mechanical training; basic electrical training; and office training. The first period, occupying roughly half the total time, deals with general manufacturing methods and workshop processes. It is in the second period that attention is directed towards the more specifically electrical aspects of the manufacture of particular types of electrical machinery or apparatus. The title "Office Training" is used to cover the acquisition of experience in the drawing office, planning and progress departments.

During the student apprenticeship it is assumed that the apprentice will be released from work on one day a week to attend a technical college course leading normally to a Higher National Certificate.

Stress is laid upon the value of the personal contacts which the apprentice makes with all classes of industrial personnel during his training period. It is largely through these contacts that he develops his sense of personal responsibility and his appreciation of the great importance of human relationships in industry. In the same connexion, mention is made of the merits of apprentice associations and similar bodies.

While the general plan developed in this report is based upon conditions obtaining in a relatively large manufacturing organisation, the special considerations affecting smaller firms and those specific to the operating side of the industry have also been given detailed attention. It is laid down as axiomatic that practical acquaintance with the basic processes employed in manufacture is needed by every engineer. For organisations such as electricity supply undertakings or telecommunication services, provision is therefore made for a considerable period of 'secondment' of the apprentice to a manufacturing organisation.

Quite apart from its specific recommendations, the report embodies a most careful analysis and appraisal of the duties and functions of the professional engineer and of the purposes towards which the various departments of his practical training should be directed. The report does not make specific reference to the important and difficult question of how best to integrate the military service requirement into the training period. It should be mentioned, however, that provision has been made by the Ministry of Labour and National Service for deferment to cover the whole of a five-year period of technical education and practical training. The details of this provision, which are set out in a leaflet, N.L.11, issued by the Ministry, are restated in the June issue of the *Journal of the Institution of Electrical Engineers* and are the subject of a further comment in the September issue of the *Journal*.

FORTHCOMING EVENTS

Monday, October 27

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "Standardization in the Electrical Industry" (to be opened by the President, Mr. P. Good).

INSTITUTION OF THE RUBBER INDUSTRY, MANCHESTER SECTION (at the Engineers' Club, Albert Square, Manchester), at 6.15 p.m.—Mr. B. Gordon Darnton: "Incidentals in Latex Treatment".

Tuesday, October 28

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Sir Edward Salisbury, F.R.S.: "The Vegetation of the Chalk", 1. "The Characteristics of the Chalk Habitat and the Chemical and Physical Factors of the Environment".

SHEFFIELD METALLURGICAL ASSOCIATION (at 198 West Street, Sheffield), at 7 p.m.—Mr. R. B. Heywood: "Photoelasticity Applied to Design Problems".

SOCIETY OF INSTRUMENT TECHNOLOGY (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. J. O. V. Vick, Mr. C. Lamond and Mr. W. Lindsay: "The Organisation of an Instrument Department in an Industrial Works".

Wednesday, October 29

INSTITUTE OF WELDING (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Mr. J. L. Adam: Presidential Address.

SOCIETY OF CHEMICAL INDUSTRY, NUTRITION PANEL OF THE FOOD GROUP (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Prof. A. Haddow and Dr. L. A. Elson: "Food and Cancer".

ROYAL INSTITUTE OF CHEMISTRY, LONDON AND SOUTH-EASTERN COUNTIES SECTION (at Woolwich Polytechnic, Woolwich, London, S.E.18), at 7 p.m.—Mr. J. G. N. Gaskin: "The Examination of Questioned Documents".

Thursday, October 30

LINNEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Rev. Prof. C. E. Raven: "Early Records of British Plants with special reference to Thomas Lawson (1630–91)"; Dr. W. S. Bristowe: "Notes on the Habits and Prey of Twenty Species of British Hunting Wasps".

---

* The Practical Training of Professional Electrical Engineers. Report of a Committee appointed by the Council of the British Electrical and Allied Manufacturers' Association, the Radio Industry Council, and the Council of the Institution of Electrical Engineers. Pp. 42. (London: Inst. Elect. Eng., 1947.) 1s.

Royal College of Surgeons of England (at Lincoln's Inn Fields, London, W.C.2), at 5 p.m.—Dr. James Craigie: "Viruses, Self-reproducing Substances and Tumours" (Imperial Cancer Research Fund Lecture).

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Dr. E. Orowan, F.R.S.: "Strength and Plasticity of Solids". (Further lectures on November 6 and 13.)

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Mr. James Bain: Third British Commonwealth and Empire Lecture.

Royal Statistical Society, Sheffield Group of the Industrial Applications Section (in Room B 1, Department of Mechanical Engineering, The University, St. George's Square, Sheffield), at 6.30 p.m.—Mr. P. Lyle: "The Application of Regression Analysis to Industrial Problems".

Royal Institute of Chemistry, Manchester and District Section (at the Engineers' Club, Albert Square, Manchester), at 7 p.m.—Mr. A. J. Curtin Cosbie: "Beer".

Pharmaceutical Society, Manchester, Salford and District Branch (joint meeting with the Guild of Public Pharmacists, in the Lecture Theatre, St. Mary's Hospital, Manchester), at 7.45 p.m.—Dr. R. Forgan: "British Contribution to Tropical Medicine".

Friday, October 31

Biochemical Society (at St. Thomas's Hospital Medical School, London, S.E.1), at 2.15 p.m.—Scientific Papers.

Physical Society (in the Physics Department, Imperial College, Imperial Institute Road, London, S.W.7), at 5 p.m.—Mr. D. G. Avery and Mr. R. Witty: "Diffusion Pumps, a Critical Discussion of Existing Theories"; Mr. J. Skrebowski: "Electron Diffraction from Anthracene, with Special Reference to the Diffuse Background".

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. T. A. Kestell: Discussion on "The Manufacture of Turbine Blades for the Whittle Engine".

North-East Coast Institution of Engineers and Shipbuilders (at the Literary and Philosophical Society, Newcastle-upon-Tyne), at 6.15 p.m.—Dr. T. W. F. Brown: "A Marine Turbine Research and Testing Station" (Andrew Laing Lecture).

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Rt. Hon. the Earl De La Warr: "Problems Facing British Agriculture".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Research Officer to take responsibility for and continuous charge of the execution of a project of research into social mobility and social class, under the direction of Mr. D. Caradog Jones—The Secretary, London School of Economics, Houghton Street, Aldwych, London, W.C.2 (October 30).

Lecturer in Biochemistry in University College, Dundee—The Secretary, The University, St. Andrews (October 31).

Assistant in the Department of Chemistry—The Secretary, The University, Aberdeen (October 31).

Teachers of (*a*) Engineering Drawing, Mathematics, Engineering Science, for Ordinary National Certificate and City and Guilds courses; (*b*) Engineering Subjects up to Higher National Certificate standard in Production Engineering; (*c*) Engineering Subjects up to Ordinary National Certificate standard in Electrical Engineering; (*d*) Chemistry, Physics, Mathematics, up to Ordinary National Certificate standard in Metallurgy—The Principal, Wandsworth Technical Institute, Wandsworth High Street, London, S.W.18 (October 31).

Lecturer to teach Physics to Intermediate and possibly B.Sc. standard, together with some Mathematics, at the Plymouth and Devonport Technical College—The Director of Education, Cobourg Street, Plymouth (November 1).

Lecturer in Biochemistry—The Secretary, Royal (Dick) Veterinary College, Summerhall, Edinburgh 9 (November 1).

Assistant Lecturer in Physics—The Registrar, University College of Wales, Aberystwyth (November 1).

Graduate Lecturer in Mathematics and Science, either Chemistry or Physics—The Principal, Dudley and Staffordshire Technical College, Dudley (November 1).

Teacher (Graduate or equivalent) of Mechanical Engineering Subjects up to the standard of Ordinary National Certificate—The Principal, Technical Institute, Killigrew Road, Falmouth (November 1).

Assistant Master (with a good degree in Science) to teach Chemistry, with Physics and Mathematics as additional subjects, at the Ashington Mining School—The Director of Education, County Hall, Newcastle-upon-Tyne 1 (November 1).

Teachers in (*a*) Mechanical Engineering, (*b*) Production Engineering, (*c*) General Science Subjects, (*d*) Automobile Engineering, at the Chance Technical College—The Chief Education Officer, 215 High Street, Smethwick (November 1).

Lecturer in Mathematics and Science in the Building Department—The Principal, Guildford County Technical College, Stoke Park, Guildford (November 1).

Assistant Lecturer in the Mining Department of the Castleford, Whitwood, Mining and Technical College—The Divisional Education Officer, 85a Carlton Street, Castleford, Yorks (November 1).

Agricultural Economists and Assistant Agricultural Economists in the Ministry of Agriculture and Fisheries and the Department of Agriculture for Scotland—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 2023 (November 6).

Teacher of Botany and Zoology for day and evening classes—The Principal, Norwood Technical Institute, Knight's Hill, London, S.E.27 (November 8).

Honours Graduate in Mathematics at the South-West Essex County Technical School, Walthamstow—The Borough Education Officer, Town Hall, Forest Road, Walthamstow, London, E.17 (November 8).

Agricultural Lecturer to the Shropshire Education Committee—The Secretary for Education, County Buildings, Shrewsbury (November 8).

Horticulturist in the Department of Agriculture, New Zealand Government—The Office of the High Commissioner for New Zealand 415 Strand, London, W.C.2 (November 10).

Lecturer in the Departments of Social Studies and Extra-Mural Studies—The Registrar, The University, Leeds 2 (November 10).

Lecturer in Moral Philosophy in the United College, St. Andrews—The Secretary, The University, St. Andrews (November 15).

Lecturer in Philosophy, and a Lecturer in Physiology, in University College, Dundee—The Secretary, The University, St Andrews (November 15).

Statistician in the General Register Office—The Secretary, Civi Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 2013 (November 15).

Chair of Sociology, and Research Posts (2), in Natal University College, Durban—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (November 24).

Assistant in Zoology for Department of National Museums, Government of Ceylon—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.N.18600 (November 24).

Lecturer in Physiology—The Registrar, University College of South Wales, Cathays Park, Cardiff (November 29).

Medical Statistician in the General Register Office—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1 quoting No. 2015 (November 29).

Professor of Psychology and Head of the Department, and a Senior Lecturer in Philosophy, at the Victoria University College Wellington, New Zealand—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (Wellington, November 30)

Senior Principal Scientific Officer to take charge of the Mathematical Section, a Principal Scientific Officer to conduct researches on problems associated with design of structures, Senior Scientific Officers (4, one for researches on reinforced concrete and the use of structural steelwork, one for mathematical research in theory of physical problems and problems of vibration and impact one physicist or physical chemist with experience in X-ray and crysta structures work, one to initiate micro-analytical work) in the Building Research Station of the Department of Scientific and Industria Research—The Secretary, Civil Service Commission, Scientific Branch 27 Grosvenor Square, London, W.1, quoting No. 2018 (December 1).

Principal Scientific Officer for Aircraft Structural Research in the Royal Aircraft Establishment, South Farnborough—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2019 (December 1).

Lecturers in (*a*) Chemistry to B.Sc. standard, and (*b*) Physics to General Degree standard—The Clerk, Northern Polytechnic Holloway, London, N.7.

Research Chemist—The Director of Research, Research Association of British Flour-Millers, Cereals Research Station, St. Albans.

Scientific Assistant (University graduate in science or agriculture)—The Director, Imperial Bureau of Animal Nutrition, Rowett Research Institute, Bucksburn, Aberdeen.

Crop Recorders—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

Assistant II in Royal Ordnance Factories—The Appointments Officer, Ministry of Labour and National Service, 1–6 Tavistock Square, London, W.C.1, quoting K.P.105.

Lecturer in Mathematics—The Registrar, The University, Reading.

Assistant III for analysis in certain Royal Ordnance Factories—The Appointments Officer, Ministry of Labour and National Service, 1–6 Tavistock Square, London, W.C.1, quoting K.P.106.

Graduate in Physics or Electronic Engineering for designing and assembly of electrical recording devices for physiological and dust measurements—The Director, Pneumokoniosis Research Unit, Llandough Hospital, near Cardiff.

Agronomist by the Directorate-General of Agriculture, Government of Iraq—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.N.18175.

Lecturer in Chemistry, a Lecturer in Mathematics, and a Lecturer in Physics, in the Science Department; a Graduate Lecturer in Mathematics, and a Graduate Lecturer in Mechanical Engineering, in the Engineering Department—The Principal, Kingston Technical College, Kingston Hall Road, Kingston-upon-Thames, Surrey.

INCENTIVES IN INDUSTRY

HOWEVER true it may have been in the past that men of science tended to disregard the intangible human element in a situation and to concentrate almost exclusively on the physical factors which they could measure, that charge could not be levelled against those who met at Dundee to take part in discussions at the British Association meeting which touched on the economic situation confronting the nation. The measures which could be adopted to increase productivity and to utilize more effectively the resources of the United Kingdom, and the contribution which science could make to that end, were never considered merely from the purely material or physical point of view. The human factor was given its full weight, and even industrial or productive efficiency was estimated not solely from the mechanical aspect but also in the light of the physiological and psychological demands which were involved in the effort required from men and women.

That was, of course, particularly true of discussions in Sections I (Physiology) and J (Psychology), but it also characterized some of the general discussions as well as various joint discussions of general interest such as those on "Man and the Machine", on selection for management and on incentives in industry. In all these there was manifest more awareness of the outlook and needs of ordinary men and women than has been apparent in some of the recent manifestations of Government policy to deal with the present situation. A striking example is to be found in Dr. R. E. Lane's fine contribution to the discussion on man and the machine, which showed a clear conception of what is involved and needed in the sphere of human relations in industry whatever form of organisation may be adopted. Nationalization alone, as the brief experience of the National Coal Board is already tending to show, is no sufficient solution, and no economic and financial system of incentives can dispense with the need for further work in this field of human relations. All possible means must be taken to eliminate the suspicions and misunderstandings which have hindered co-operation in the past, and to promote both an atmosphere and an outlook which make for co-operation and mutual confidence.

That is the first condition of increased productivity, and the symposium on incentives in industry arranged by Sections F (Economics) and J (Psychology) on September 2 demonstrated the crucial importance of such personal satisfactions. Dr. J. A. Bowie, in opening this discussion, urged that the psychological conditions are even more important than the physical ones. Incentives as commonly conceived may even offer no real contribution in the battle for output, and he thought it possible that no system of incentives would work well or permanently within the limits of the present system. What is needed is a sense of participation, which may only be secured by radical changes in factory life dispelling the present misunderstandings and distrust. A new psycho-sociological approach and further research in the field of incentives might make most important contributions in securing the satisfaction in work and sense of participation which would provide the real remedy for so much industrial unrest and low productivity.

Much the same point of view was urged by Mrs. W. Raphael, of the National Institute of Industrial Psychology, from the results of attitude surveys covering 15,000 workers of all grades in industry, conducted by the staff of the Institute in recent years. Financial incentives are not all-important, although they may be very significant if the workers do not consider their pay to be 'reasonable' or 'fair'. Satisfaction in the job itself is important among managerial and skilled workers, but less often in skilled and unskilled work, and can be increased by good vocational guidance, selection and training for the job. Participation, the sense of mattering to the organisation, and knowing about and possibly influencing its activities are important incentives which should be stimulated by such methods as joint consultation in its widest sense.

The National Institute of Industrial Psychology has obviously experience which could be of great value to the numerous joint production committees and to other bodies concerned with joint consultation as well as to management, including those organisations supporting research in the management field. That experience will no doubt be fully available to the British Institute of Management; and a body such as the National Staff Administrative College may well be expected to assist in the wider and wiser study and use of incentives throughout industry. Mr. Dennis Chapman's review of the factors that make for harmonious relations between working groups indicated other fields for research. Like Mrs. Raphael, he directed attention to the importance of environment, while Mr. C. Madge, of "Mass Observation", again emphasized that financial incentives are only one factor in a complex situation. Payment by results and bonus systems are only really successful when applied by managements who recognize this limitation. Few people work as hard as they are physically capable of doing, and restriction of output may be both conscious and unconscious, originating sometimes in the fear of unemployment through over-production. Moreover, there are demands for leisure, for less responsibility and for easier work, which can be as real and potent as the demand for material goods.

Mr. Madge urged that the principal way to increase production is by improvements in machines and in the physical organisation of the factory; but it is easy to see how, at a time when the worker finds it difficult to exchange wages or salaries for the material goods he desires, the pulling power of the demand for leisure and easier work can easily become more potent, even if we leave out of account the effect of six years of war. The balance will most certainly not be redressed by exhortation and organisation alone. As regards the building industry, which is among the least progressive and most wasteful of British industries, neglectful of research and indifferent to innovation, the scale of values of the operatives differs in important respects from that of many other industrial workers. To most of them a steady guaranteed wage is more important than higher but less regular earnings obtained either through a rise in rates or through payment by results. Most of them, too, are unwilling to accept increased payment under a system which, in their view, would inhibit or destroy other strong motives such as pride in craftsmanship and the sense of comradeship. Miss N. M. Davis's contribution dealing with this industry was of special interest.

It is clear that here as elsewhere the problem is really one of building co-operation into our whole industrial system, and in an industry such as the building industry this is the only means of achieving the immediate results that are imperative. Technical improvements resulting from research may make large contributions to increased efficiency in the long run, but for immediate results it is upon efficient management as well as a new approach to incentives, conditions of employment and welfare that we must rely.

There is, in fact, urgent need for a scientific approach to the problems of incentives and human relations, both in private and nationalized industry; and the need is the more imperative because whatever shortcomings may be urged against private industry, there is no evidence that industry directed by the State itself would be either more efficient or freer from labour disputes and unrest. The evidence so far indicates a conspicuous failure of the idea of the public interest and a concern for the welfare of the whole community to permeate the rank and file of the employees of nationalized industry. This, however, is our fundamental need, and until it is true of industry generally, whatever the form of its organisation, we are unlikely to see the full productive effort that is required.

A thoughtful paper on this point has been contributed by Dr. Ordway Teed on "Public-Mindedness through Co-operation" (*Ann. Amer. Acad. Pol. and Soc. Sci.*, Nov. 1946). Dr. Teed sees no quick and easy way to industrial peace, but he maintains firmly that collective bargaining as the beginning of responsible constitutional government in industry is the primary public interest. Equally, he insists that the pattern of joint management – labour working arrangements must be voluntary, and he develops his argument on similar lines to Colonel Urwick and Mr. C. C. Renold in Great Britain.

The conception of the common interest requires, however, the development of much more effective means of informing all parties of the reasons for decisions and policies, so as to secure their consent and support, and there is room for inquiry into the best means of achieving this. We cannot wisely assume that the production committee or works council is the only, or even the best, means of doing so. Moreover, when we have succeeded here, we may find that the whole order of importance of incentives is changed. We may, in fact, find that though the financial incentive needs to be supplemented by others, which it is the urgent duty of management to explore and apply, such as pride in the finished product and a knowledge of its value to the country, the possibilities of group leadership and competition, and the latent desire for self-expression, it may, subject to appropriate safeguards, afford the most effective and compelling motive of all.

One aspect, often forgotten, is well brought out in some of the inquiries already made; it is not for the monetary reward itself that the financial incentive is important, but for the satisfaction which that monetary reward makes possible. What needs to be remembered is that once the monetary reward is sufficient to meet elementary and basic human needs, it makes possible the satisfaction of other needs according to individual choice. It is partly because controls and shortages are preventing such satisfactions that the financial incentive has proved ineffective. But, however effective the service motive may become, no alternative to the financial incentive which offers the same opportunity and freedom of choice has yet been proposed.

Prof. H. S. Kirkcaldy's reminder to the planner, in his "Industrial Relations in Conditions of Full Employment" (Cambridge University Press, 1945), that the ultimate judge of essential liberties is the individual citizen or worker himself is equally pertinent in this matter of incentives, and in so far as the financial incentive permits the exercise of the freedom of choice it should not be discounted so severely as in the discussion at Dundee. The point is one that the Government, too, has widely disregarded. Incentives need to be tangible and easily visualized by the worker; when, as at present, Government policy has deliberately removed both the 'carrot' and the 'stick', it is not surprising that production lags.

The effort to build up co-operation effectively which, as Prof. Elton Mayo has remarked, is the fundamental problem we face to-day, must take full account of this aspect of freedom. It accentuates the importance of the question of the communication of knowledge and information; both the capacity of an individual to communicate his feelings and ideas to another, and that of groups to communicate effectively and intimately with each other. Much that was said at these discussions at the British Association's meeting at Dundee confirms the correctness of Prof. Mayo's view that social study should begin with careful observation in this very field. Here our civilization is most defective, and although we have reached some appreciation of the fact that collaboration in an industrial society cannot be left to chance, we have yet to realize that there is no simple or rapid solution. Patient, pedestrian study of the wholly neglected problem of the determinants of spontaneous participation is, as Prof. Mayo observes, the line of advance, and imperative as is the application of scientific method to the study of the social situations involved here and elsewhere in industry and in society, the scientific approach offers no promise of immediate solutions. The British Association discussions should not only lead to the more widespread study of these questions, but should also assist a more sober and realistic appreciation of what is involved and the conditions of success, and above all the importance of extending and developing both technical and also social skill and human co-operative capacities. It would be disastrous to rely entirely on the production committees and works councils without exploring this whole field of the techniques to determine the effects of action in the social field, the means of securing spontaneous co-operation alike of groups and of individuals. The problem of incentives is only one facet of the larger one of industrial relations, which in turn is, as we are now realizing, part of that of the relations between groups and individuals in the society which constitutes the whole nation. Objective inquiry there must be, and action and policy must increasingly be based on the results of such inquiry and the techniques developed thereby, at the level of Government, in the factory, the workshop and the laboratory. Ultimately it is the task of management to use that knowledge and technique to serve the common ends, and no amount of exhortation and precept can be a substitute for the effective leadership which is the mark of good management and also of good government.

NEWTON AS CIVIL SERVANT

Newton at the Mint

By Sir John Craig. Pp. viii+128+4 plates. (Cambridge: At the University Press, 1946.) 7*s*. 6*d*. net.

IN 1696, when he was fifty-three years of age, Newton was appointed warden of the Mint, and in 1699 he was promoted to the master's place, which he held to the date of his death. The last thirty-one years of his life were thus passed in a public service which, if not as a whole arduous, yet occupied much of his time and was, on occasion, vexatious and exacting. So much can be found in any biography, but hitherto there has been no detailed account of this aspect of the great man's life, nor, indeed, are the necessary sources within reach of all.

Sir John Craig, who now comes forward to fill the gap, is particularly fitted for the task, having himself long been deputy master of the Mint, where he has had access to most of Newton's writings on matters concerning coinage. He has already, with Prof. Shirras, examined Newton's monetary theories in the *Economic Journal* of June 1945, although without reference to certain papers now available to him. In the little book before us he explains the very complicated history of the coinage of Britain, in particular the recoinage round about the beginning of the eighteenth century; the structure and personnel of the Mint, including such matters as the respective duties of the warden and the master; the many technical problems of producing coin at the period in question and the fixing of the intrinsic value; and, in particular, Newton's part in it all.

The book is written from the point of view of one familiar not only with the manufacturing problems of coinage but also with the economics of metal currency and of foreign exchange, which makes it in parts tough reading for the cloistered physicist. All the more does it show that Newton was thoroughly competent in financial matters, of which he wrote with his usual incisiveness, as exemplified, for instance, by the following passage.

" 'Tis mere opinion that sets a value upon money; we value it because with it we can purchase all sorts of commodities, and the same opinion sets a like value upon paper security. . . . All the difference is that value of gold and silver is set upon their internal substance or matter and therefore is called intrinsic, and the value of paper security upon the apparent form of the writing and therefore called extrinsic, and that the value of the former is more universal than that of the latter."

He was also, it appears, a good organiser and, surprisingly enough, tactful and successful in his personal relations, but he was "averse from all novelties" and made no notable innovations. How different, in every respect, is his record as a Civil servant from his record as a man of science.

The Great Recoinage which began early in 1696 is usually represented as a national melioration, for which Newton was largely responsible. For example, Mr. George Roberts, one-time director of the United States Mint, says of it, "unquestionably it was a great reform, creditable to all who had any part in it". Alfred Marshall termed it "the necessary but drastic remedy, which the Government was applying in 1695 for the corrupt condition of the coinage". Sir John states bluntly that it was a social crime and, in any case, the principles had been determined before Newton's first appointment, so that he was only the agent for putting into practice decisions already reached. The difficulties with which he had to contend in this capacity, including the constant disputes between the garrison of the Tower, in which the Mint was situate, and the personnel of the Mint; the prosecution of coiners; and the trouble with the standards, described with many other concerns in a chapter entitled "All Kinds of Vexations", are clearly depicted. A matter of considerable general interest that occurred towards the end of Newton's life was the affair of "Wood's halfpence", still remembered from Swift's attacks in the "Drapier Letters". Apparently the coinage in question would have been better in all particulars than any issued before in Ireland, but in view of the unjustified, but violent, agitation against it, it was withdrawn. "The English Government had no inclination to do unpopular good by force." Newton's part in the whole affair was, of course, purely technical.

The student of Newton will find in this book many personal details of general interest. Typically enough, we find Newton, who was always a man of his hands, carrying out assays himself, no doubt to see how it was done, since, apparently, he made no improvements. Sir John concludes that Newton wrote at tremendous speed, which is consistent with his habit of perpetually redrafting, of which many examples are given. Anyone who has studied the catalogue of the Sotheby sale of Newton papers in 1936 will find no difficulty in accepting this conclusion. The author opines that these pains and scruples and afterthoughts in drafting may have fostered Newton's lifelong aversion from publication: perhaps we might rather say that the redrafting and the shrinking from publication were both symptoms of his horror of controversy, to which ambiguous passages might give rise. Not known to everybody is the fact, here recorded, that Newton changed the Royal Society meeting day from Wednesday to the present Thursday, because Wednesday was the Mint's day for paying out coin.

Enough has been said to make it clear that this is a book which everyone seriously interested in Newton must possess. It is embellished by many a pleasant turn of phrase, as when the author refers to Halifax's association with Catherine Barton as "a morganatic alliance without benefit of clergy", or when he says of a phrase in an Act "it must signify something, as an absurdity of Parliament was, legally, unthinkable, but each learned man favoured a different something". The general merit of the little work being fairly acknowledged, it will not, I trust, appear ungracious to point out a few minor deficiencies. The author would seem not to have consulted, or, at any rate, made full use of, either De Morgan or Edelston, and when he mentions the "famous report of 21 September 1717", which was long a weapon in the controversy between the bimetallists and the champions of the gold standard, he does not give the references where the ordinary reader can find it and other reports, namely, the "Macclesfield Correspondence" and "A Short Essay on Coin"; nor does he quote McCulloch's "Select Collection of Tracts on Money" or refer to Horton's "Silver Pound". In general, the references which the serious student needs are lacking. "Mr. Gyre's house" at Pudlicot should, according to the reprint of the letter in De Morgan, be "Mr. Ayre's house", which sounds more probable. To say of the prize of £20,000 for the longitude that "one half of this was won by John Harrison in 1726" is so manifold an error that one can only refer the reader to R. T. Gould's "The Marine Chronometer". The reference to Brewster in this matter is wrongly given. I doubt if the statement that Newton was knighted to attract voters can possibly be made good. But these are trifles, and we would wish to end on a note of thanks to Sir John for the learned labour which he has put into this informative little work. E. N. DA C. ANDRADE

GENETICS AND MAN

Genetics, Medicine and Man

By H. J. Muller, C. C. Little and Laurence H. Snyder. Pp. xi+158. (Ithaca, N.Y.: Cornell University Press; London: Oxford University Press, 1947.) 2.25 dollars.

THIS book presents the subject-matter of the Messenger Lectures delivered in 1945 at Cornell University by three geneticists, each outstanding in his own particular field. The lectures were addressed to a general audience and dealt with (*a*) the fundamental principles of genetics (H. J. Muller), (*b*) parental influence and growth of individuality (C. C. Little) and (*c*) the special genetics of man (L. H. Snyder).

As was to be expected, Prof. Muller presents a most attractive account of genetical fact and theory, simple yet meticulously accurate in statement, clothed with pretty notions and bedecked with stimulating ideas. To him the dance of the genes is a spectacle to be seen and an entertainment to be enjoyed. He has a great facility for enabling an audience to share his pleasure. To know or to hear him is to appreciate the excitement of adventure that can be encountered in the genetical field and the quiet joy that comes with an understanding of its principles.

Dr. Little is another example of the relative importance of the apostle in the attraction of interest and attention to the science which he represents. Here is the picture of a man who turned away from the glamour and power of high positions of academic and political eminence to return to the quiet aloofness of a laboratory. The account which he gives of the discoveries made by himself and his colleagues in the Roscoe B. Jackson Memorial Laboratory at Bar Harbor reveals in the clearest possible fashion that the greatest gifts that science can give to a man are intellectual honesty of the highest order, an emotional serenity and a great faith in the expanding dignity of mankind.

Prof. Snyder is a recognized leader in the field of medical genetics, to which subject he himself has made many notable contributions. There is none better qualified than he to show the place of genetics in medicine, its importance in the search for etiological factors and its limitations. In this brief narrative he easily succeeds in displaying the role of the gene in the causation of human defect and derangement.

A course of such lectures by such men could not do otherwise than demonstrate in the clearest possible fashion the important bearing that genetic fact and theory have upon a wide diversity of human and social interests and activities.

This book will claim the attention of all geneticists, since all will wish to see how these three colleagues of theirs tackle the problem of making genetics attractive to the general audience and reader. It can be strongly recommended to practitioners of medicine and to men of science other than biological; in fact, to all who seek an easy yet strictly accurate account of what genetics has become and of what it can promise in application. F. A. E. CREW

THE PROCESS OF PUBERTY

Adolescent Sterility

A Study in the Comparative Physiology of the Infecundity of the Adolescent Organism in Mammals and Man. By Assoc. Prof. M. F. Ashley-Montagu. Pp. ix+148. (Springfield, Ill.: Charles C. Thomas; Toronto: Ryerson Press, 1946.) 3.50 dollars.

IN "Adolescent Sterility" Dr. Ashley-Montagu assembles an impressive body of facts which show that puberty in the female is not a sudden assumption of the capacity to reproduce, but a slow process of development during which the ovaries and the accessory reproductive organs develop their rhythm of physiological activity. Ovulation, and especially ovulation as a fairly regular phenomenon in the sexual cycle, is not established until the end of the pubertal phase. Consequently it follows that conception is unlikely to follow mating during a mammal's first sexual cycles, and that a period of what is called "adolescent sterility" is associated with the process of puberty. Dr. Ashley-Montagu defines the term as the interval of time from the first œstrus during which, in a given population, a majority of normally developing individuals are incapable of conceiving and remain sterile, while those which do conceive either suffer a high mortality-rate or exhibit a high proportion of abortions or miscarriages. This latter effect is attributed to the fact that at the time of the first ovulations the body "as a whole" may not have reached a mature enough state to sustain the process of reproduction.

Dr. Ashley-Montagu supports these generalities with experimental observations that have been made on mice, cows, rhesus monkeys and chimpanzees, and with a number of statistical observations about human reproduction in different parts of the globe. These show that the percentage sterility and the average interval between marriage and the birth of the first child are greater in women under than over the age of twenty, and that "prior to the age of 20 years the process of childbearing constitutes a hazard to the life of both mother and child, which increases in proportion to the youthfulness of the mother and decreases to a minimum at maturity".

Dr. Ashley-Montagu has personally contributed little to the body of evidence which he reviews, for he is an anthropologist, not a physiologist. His wide reading, however, has provided him with an extensive knowledge of a field not quite his own. Unfortunately it is also reflected in a laboured treatment of the subject, in excessive quotation, and in the discussion of topics which are somewhat remote from the main theme. This is a drawback in a short book; but students will no doubt willingly put up with this fault in return for the able summary which Dr. Ashley-Montagu provides. S. ZUCKERMAN

OCEANIC BIRDS: A PICTORIAL SURVEY

British Sea Birds

Written and illustrated by C. A. Gibson-Hill. Pp. 144 (48 plates). (London: H. F. and G. Witherby, Ltd., 1947.) 18s. net.

THE author selects twenty-four of the most oceanic of the sea-birds which breed in the British Isles, and makes them the subject of a series of thirteen short essays. There is nothing original about these essays—they are the result of a photographic tour made by the author in 1946 around the principal accessible islands and coast sites, and in one brief summer of bad weather the author makes no claim to having discovered any new facts. Yet he has managed to convey to the reader something of the charm of the islands and their avian inhabitants. He has drawn, with acknowledgments, upon the original observations published by other workers, including the recently published work of American ornithologists, who made progress denied to British observers during the war years. This information is presented in a straightforward style, and in a large type that is refreshingly easy to read. Line-drawings of the heads of related species showing seasonal plumage changes are quite useful, although some are redundant because the photographs show these differences more clearly. The elementary life-history of each bird is sketched out—breeding, feeding and migration, and a note added on the derivation of the common name.

Considering the high price of this book, and the interest that is taken in Britain in sea-birds, the text is disappointingly brief. Distribution and field characters and notes on rarer species are squeezed into a concluding chapter with distribution maps, but these are not as accurate as one could wish. The photographs, taken with a miniature camera, speak of the patience and skill of the author, and although they suffer somewhat from over-enlargement and from being grouped together without relation to the text, they are most attractive. One has the impression that the author set out to make a book of photographs of sea-birds, and decided afterwards to expand the captions into brief chapters. As an advertisement or pictorial introduction to the study of British sea-birds the book is of value to the beginner. R. M. LOCKLEY

The Cult of the Superman

A Study of the Idea of Heroism in Carlyle and Nietzsche, with Notes on other Hero-Worshippers of Modern Times. By Eric Bentley. Pp. xxiii + 277. (London: Robert Hale, Ltd., 1947.) 12*s.* 6*d.* net.

THIS is a discussion of the cult of the hero considered as the shaper of human destinies; a cult started by Carlyle, developed by Nietzsche and continued by Wagner, Bernard Shaw, Spengler, Stefan George and D. H. Lawrence. The last three, though Mr. Bentley does his best to polish them up, are just dim. Shaw, who is anything but dim, is only a hero-worshipper spasmodically in his Wagnerite moods. Wagner had great influence in his day, but still is only a lightweight. Were even the first two heavyweights? Mr. Bentley thinks they were or he would not have written this witty and provocative book. They have been labelled proto-fascists; but the label, even if it is appropriate, does not make their ideas negligible. Fascism takes account of elements in human nature which liberals and rationalists have refused to see. Carlyle and Nietzsche did see that mass-production of machines and the mechanization of the human masses was not the road to any paradise, capitalist or proletarian. They did foretell more about the twentieth century than any of their contemporaries. Marx and Engels unaccountably omitted to predict Lenin and Stalin; Carlyle and Nietzsche made a very good shot at them (not to mention Hitler, Mussolini and others). But, as Mr. Bentley shows, the doctrine of the hero has always been confused and inconsistent, and always been propounded by those whose attitude to life is ambivalent. Mr. Bentley himself is ambivalent towards his subject. He thinks that this sound and fury signified something but finds it difficult to explain what. He concludes with the mild observation that democracy needs leaders, an aristocracy of talent; a conclusion that would infuriate Carlyle or Nietzsche, who did not admire the characteristic democratic leader of the American or British pattern.

A. D. R.

Précis de dermatologie

Par J. Darier, A. Civatte et A. Tzanck. Cinquième édition par A. Civatte. Pp. v + 1,152. (Paris: Masson et Cie., 1947.) 1,700 francs.

THE appearance of a fifth edition of Darier's "Précis de Dermatologie" is an event of importance. The last edition appeared in 1928 and has long been exhausted. This book has become in France, where dermatology is an art less confined to the specialist than it is in Britain, part of the library of nearly every student.

The title is misleading, as the scope is more nearly that of a text-book than a précis. It is intended as a guide to diagnosis for the practitioner and as an introduction to dermatology for the student. General principles of treatment are indicated, but detail is omitted.

The book is divided into two main parts. The first classifies the skin diseases according to morphological appearances; the second part deals specifically with diseases grouped according to causal agents.

This is a complete guide to dermatology without omission of the rarities, and it is a book which no specialist need disdain.

The new edition has been edited and brought up to date by Dr. Civatte since the death of Darier. He is to be congratulated on his work, which includes all the recent advances in the subject in diagnostic measures, treatment methods, etc. This has been achieved without altering the fundamental design set by Darier. Many good new illustrations have been added.

I do not hesitate to say that this work has no equal in the English language, and that the new edition will consolidate its high reputation in the exacting school of French dermatology. James Marshall

The Theory of Functions of Real Variables

By Prof. Lawrence M. Graves. Pp. x + 300. (New York and London: McGraw-Hill Book Co. Inc., 1946.) 20*s.*

THE exposition of a mathematical subject in its early stages of development is apt to require a bulky volume; the appearance of this concise treatise, covering so much ground, would consequently suggest that the theory of functions of real variables is now coming to maturity. Conciseness is partly achieved by the extensive use, especially in the earlier part of the book, of the symbolism of mathematical logic. In order to accustom the reader to the use of this symbolic method, many statements in the earlier chapters are given in duplicate, first in symbols and then in ordinary language.

The subjects covered in three hundred pages include the following: the real number system, sets of points, limits, the Riemann integral, uniform convergence, implicit functions, the Lebesgue integral and the Stieltjes integral. The exposition is careful and thorough, but so condensed that the beginner would find its perusal far from easy without the assistance of lectures or of a tutor: indeed, the author suggests as much in his preface.

It seems strange that, in his limit notation, the author makes use of the obsolete sign of equality, and not of the arrow-head as introduced by Leathem and Bromwich. T. M. M.

Physical Chemistry for Colleges

A Course of Instruction based upon the Fundamental Laws of Chemistry. By Prof. E. B. Millard. (International Chemical Series.) Sixth edition. Pp. ix + 682. (New York and London: McGraw-Hill Book Co., Inc., 1946.) 22*s.* 6*d.*

Fundamental Principles of Physical Chemistry

By Prof. Carl F. Prutton and Assoc. Prof. Samuel H. Maron. Pp. x + 780. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1944.) 25*s.* net.

THESE two books are excellent examples of modern American texts on physical chemistry. The continued usefulness of the former is attested by the five previous editions, while the latter is a new work. Both make a thermodynamic approach to the subject and cover a considerable amount of ground. Although stated to be for beginners and designed for a single year's work, they do not confine themselves to the elements of the subject (which are covered very agreeably); they take in their stride such complex affairs as the Debye–Hückel theory, activity coefficients, the third law of thermodynamics, rotational spectra, modern formulations of reaction kinetics, etc. Remembering his own experience as a teacher, it is something of a mystery to the writer how the American student of chemistry and chemical engineering manages to digest all this in so short a time. Both books are well provided with problems.

J. A. V. Butler

GEOLOGY AND THE FUTURE OF COAL SUPPLIES

IN the presidential address to Section C (Geology) of the British Association, delivered at Dundee on September 1, Dr. Murray Macgregor stressed the vital need for closer co-operation between the miner and the geologist for the better-planned exploitation of the coal resources of Great Britain ; his address was followed by a discussion on the future prospects of those supplies.

In opening the discussion, Prof. H. G. A. Hickling suggested the importance of attention to the various classes of coal and their most effective use, rather than the estimation of total reserves. Even with the wasteful usage of former years, the total supply is unlikely to approach exhaustion within any period for which it is reasonable to plan at this time ; but it is less certain that one can be equally optimistic regarding some of the most valuable varieties. The first-class coking-coals, the anthracites and some other classes have hitherto been obtainable only from very limited areas in Great Britain, where they have been heavily wrought and the reserves greatly reduced. It is consequently a matter of major importance whether the remaining reserves are likely to yield a greater or smaller proportion of such types. Any useful forecast must be based on a knowledge of the distribution of existing coal types and its causes.

Coals vary in their characteristics from two main causes : first, from variation in the original deposit in respect of the contributory plant material, its mode and extent of decay and the nature and quantity of associated mineral matter ; and secondly, as the result of the varying extent of subsequent alteration under geological influences. Regarding the first, the long-familiar division of coals into 'brights' and 'hards' corresponds broadly to those ('brights') which have been formed mainly from pieces of organically saturated wood and bark, in contrast with the 'hards', which consist of a far more highly disintegrated mass of the most resistant plant residues, forming a minute micro-conglomerate. Chemical examination indicates that the substance of the bright coal was originally of relatively constant composition. The duller component is extremely variable both in visible constitution and in chemical characteristics.

Most seams contain a mixture of the two principal types of material. Their varying proportions, and especially the constitution of the dull coal, give rise to the characteristics of the different seams. The extensive investigations carried out by the Fuel Survey in Great Britain during the past thirty years have shown that individual seams commonly maintain their special features over considerable areas, while all the seams in any field usually show similar changes in 'rank' as they are traced from one part of the field to another. These latter changes are most familiarly indicated by alteration of the percentage of 'volatile' yielded by the coal on heating ; this diminishing progressively from the low-rank bituminous coals through the gas-coals, coking-coals and steam-coals to the highest grade anthracites.

Whether the variation of rank in any field be great or small, it follows the same pattern in all seams. Similar changes of rank are found in the vertical sequence of seams at any given point, though this very significant fact is commonly obscured by the individual characteristics of the seams unless a long vertical series can be examined. The rank rises with increasing depth, and accumulating evidence indicates considerable regularity in the rate of change. Our growing knowledge of the causes of the differences among coals leads to the possibility of a more accurate forecast of the probable quality of our remaining resources, and to the conclusion that, while we shall be compelled to work at greater depths, there will be some compensation from the inclusion of a measurably greater proportion of the higher-rank coals.

Dr. C. A. Seyler described his recent investigations into the mode of change of the main constituent (vitrains) of normal coals, as indicated by their increase of reflecting power as the coal advances in rank. Contrary to expectation, this alteration appears to be discontinuous, the reflecting power changing abruptly through a series of nine steps in geometrical progression, and terminating with the highest member, fusinite. In any coal the bulk of the vitrain belongs to one of the lower members, with smaller quantities of the next two or three and usually a little fusinite. As the rank of the seam advances to a critical point, each component present changes its reflecting power (and presumably its composition) one step upward in the series ; except, of course, the fusinite.

Exactly similar stepwise changes of the vitrinites are observed in coals which have been subjected to progressive alteration by the thermal metamorphism of sills and dykes. This is shown with exceptional completeness in the case of a Sumatra lignite, which has been changed progressively to an anthracitic condition through a series of stages closely corresponding with normal coals. It seems to afford conclusive proof that heat (and possibly pressure) is capable of accounting for the varying stages of alteration of normal coals.

Dr. A. C. Monkhouse gave an account of the work and results of the Physical and Chemical Survey of Coal Resources during the past twenty-five years by the nine coalfield survey laboratories and the Fuel Research Station at Greenwich. This has given a knowledge of the coal resources of Great Britain more complete than that of any other country in the world. Most of the important seams in all the principal fields have been examined in detail in many places. Analysis band by band has frequently shown how the quality of the coal may be improved by excluding harmful bands, or how particular sections may be put to specially valuable uses. The regional variation of the seams has been traced in detail, and the ground securely laid for a forecast of the changes likely to be encountered as the seams are worked into new areas. Valuable evidence of the variation of coals in the vertical sequence has been obtained by the examination of the series of seams encountered in the exploratory borings for oil.

Following the nationalization of the coal reserves, a rapid survey was undertaken so that a final assessment might be based not only on the quantity but also on a carefully defined estimate of the qualities of the coals likely to be worked in the various royalties during the 'valuation period' (usually a hundred years). The coals were divided into six classes defined by volatile yield and coking properties, and the whole results finally subjected to mechanical analysis so as to reveal the total amounts of each group likely to be worked. This could be compared with the estimated reserves of each type, and led to the satisfactory conclusion that no type is likely to be exhausted during the next century.

The work of the organisation has naturally been forced to branch in many directions as ever-growing demands have been made upon it. Much work has been devoted to examination and advice related to the open-cast coal developments. Problems concerning the sizing, cleaning and breakage of coal have been investigated. Weathering and storage have been studied, and methods developed for the preservation of coal-dumps with tar cover. The selection and treatment of coals to serve producer-gas units for road-transport vehicles was undertaken during the War, as also the selection of coals to produce active carbon. The loss of the normal sources of sulphur led to an active search for pyritic waste from coal, and the production of 33,000 tons of sulphuric acid from this source. The accumulated knowledge and experience were also utilized for the solution of problems for the Service departments. For the future, the work of this organisation must be of the highest value for the proper planning of coal production and for its most economic and profitable use by the consumer.

As an indication of the need for intensive geological study and practical exploration, Dr. G. H. Mitchell submitted a contribution concerning the problem as it affects the Midland coalfields of Coalbrookdale, the Wyre Forest, South Staffordshire, Warwickshire, South Derbyshire and Leicestershire. These are parts of a natural area of related coalfields containing seams of a limited range of low- and medium-rank coals. The industry and the resultant centres of dense population within the area are founded on these coals, and especially on those of better quality. Within the life-time of the next generation there must be a steady decline in output unless new fields are discovered. Even sooner, the deterioration in average quality as a result of the exhaustion of the better seams will become a serious problem. The matter is therefore urgent.

The geological sequence within each of the fields is fairly completely known. Evidence for the estimation of their mutual relations is available in the marine beds and mussel bands which have been traced from field to field. The actual position, extent and depth of such extensions of these fields as may still lie concealed below the younger rocks of the intervening areas may be doubtfully inferred as the result of intensive geological study. Exhaustive investigation of the evidence of Carboniferous and post-Carboniferous earth-movements, and of the consequent sedimentation and periods of erosion, must form the basis of a forecast. But results can be no more than probabilities and are inadequate for practical development. They can, however, suggest where borings may be located so as to yield the most valuable information. A programme of intensive work, in which boring and geological study proceed hand in hand, is likely to produce practical results at a cost quite infinitesimal in relation to the national importance of the matters involved. Since, however, the complexity of the problems we have now to face in the search for new areas of coal is greater than those hitherto encountered, the boring and exploration programme must needs be far more extensive than any previously undertaken.

Dr. G. M. Lees delivered a communication prepared in conjunction with L. N. Falcon on the relation of the search for oil to the discovery of new coalfields. One considerable buried field has already been proved in central Lincolnshire. Although too deep for present-day exploitation, there is good prospect that it may be at a lesser depth near the Wash. Farther south-eastward, extension of the Nottinghamshire coalfield has also been proved, with the possibility that it may link up with the Wash area. It is a remarkable fact that the Kent coalfield should be the sole example of a buried field hitherto located in Great Britain.

The search for oil has to commence from speculative geological deduction based on the limited surface evidence. Since the rocks and structures concerned are for the most part buried under unconformable cover, the most widespread indications, gathered from the Continent of Europe as well as from Britain, must be brought under review. Selected areas of sufficient promise are then subjected to gravity and magnetic survey to gain a broad generalized picture of the underground structure. From this background the most likely areas are more closely examined by seismic survey, and finally, where indications seem favourable, proved by boring.

The Midlands and south-central England have been generally studied. Of the areas selected within that region, one around Market Drayton and between there and Burton-on-Trent has been subjected to seismic survey. Boring will shortly be commenced. In three other areas, gravity and magnetic survey have been in progress for some twenty months, and results are now being analysed. These are: (1) an area in Wiltshire, where an eastward extension of the Somerset coalfield, or possibly an independent field, may be proved; (2) the Cotswold country in Gloucestershire, and perhaps southern Worcestershire; and (3) certain areas in Oxfordshire, possibly between Oxford and Reading. In addition to these, eastern Essex has been indicated for further study, while numerous other areas exist outside the present programme of investigation where extensions of existing fields or new fields may be found.

Dr. Lees concluded with special emphasis on the need for national effort in this matter. The present programme of private boring can only be subsidiary to the search for oil and at any time may have to be abandoned. Such a possibility is scarcely to be dispassionately contemplated.

The last contribution, from Dr. R. Holroyd, was on coal as a chemical raw material. Chemical industry is largely dependent on the availability of coking-coals; first, for the phenol, cresol, naphthalene and anthracene extracted from the two million tons of coal tar produced annually by coal carbonization, as well as benzene, toluene, xylene, etc.; and secondly, for the production of water-gas or hydrogen for chemical synthesis from about one million tons of coke with high melting-point ash.

The yield of aromatic raw materials is only about 1·5 per cent of the weight of the coal. In the past, this output of by-product by the carbonization industry has sufficed for chemical needs. Now, the anticipated demand greatly exceeds the supply, and investigation has therefore been directed to other sources. Considerable progress has been made in the development of petroleum-cracking plants, and it is probable that the chemical industry in future will be far less dependent on carbonization by-products, though it will continue to provide an outlet for them in so far as they can be produced economically.

The demand for 'synthetic gas' (carbon monoxide and hydrogen or hydrogen alone) is likely to increase considerably. The present high cost has compelled close examination of the efficiency of existing methods for its production and the investigation of new methods. A provisional scheme for a continuous process based on the 'fluid-solid' technique was described as offering considerable promise. German methods using oxygen may also be developed. While increased efficiency and lower costs must be the primary objective, it is likely that an even more important outcome may be the possibility of using a wider range of coals.

Thus it would appear that the chemical industry in future may be less exacting in its demands regarding types of coal and may obtain a large proportion of its raw materials from other sources. At the same time, it must remain a major consumer of coal as fuel, and its prosperity will depend on ample supplies.

George Hickling

BRITISH NON-FERROUS METALS RESEARCH ASSOCIATION

After the annual general meeting of the British Non-Ferrous Metals Research Association on July 10, members and a small number of visitors were shown the laboratory buildings and facilities which the Association now possesses.

In 1930 the first of the Association's laboratories was established by conversion of a small factory near Euston Station, London, and just prior to the War additional laboratories were built on an adjacent site. During the War the original laboratory block was destroyed by enemy action, although the new building was fortunately undamaged. In preparation for post-war expansion, adjacent premises were afterwards purchased; their conversion is now almost completed, and application has been made for a licence to rebuild the war-damaged property. Completion of the present plans will provide a series of laboratories with a total of about 32,000 sq. ft. of floor space in an accessible position in central London. The extension of the laboratories and the corresponding increase in scientific staff, which together will enable a wider range of metallurgical work to be undertaken, have been made possible by the steady and continuing increase in the financial support which the Association receives from industry.

Expansion of the laboratory facilities was particularly required in the Physics, Mechanical Testing and Corrosion Sections, and new accommodation was needed for the recently formed Metal Finishing Section and to house metal-working equipment. Such metal-working equipment will be installed as is needed to prepare experimental alloys in wrought form for test purposes, but it is not intended for fundamental research on the working behaviour of metals and alloys, as it is hoped that such work will be done co-operatively with the British Iron and Steel Research Association in the latter's projected Flow of Metals Research Laboratory.

In accordance with the Association's policy of developing and using modern physical methods for the examination of metals, a Metropolitan-Vickers electron microscope has recently been installed in the physics laboratory and a study is being made of existing replica techniques. Attention will also be paid to the possibility of developing new replica techniques and alternative methods of examining metals in this instrument. Its full potentialities in metallurgical research have not yet been assessed, as its successful use depends so much on the development of satisfactory techniques, but a critical experimental survey is being made of its possible field of use so that members can be suitably advised. The high-tension source of the electron microscope will also be used for electron diffraction work, apparatus for which is being built in the Association's workshops. The Association's pioneering work of many years ago in the application of the spectrograph to the quantitative analysis of non-ferrous metals and alloys is being continued by a systematic study of the use of multiplier photocells in recording spectra and for investigation of excitation conditions.

The expansion of the Mechanical Testing Laboratory is largely to enable more work on creep and fatigue testing to be carried out, including fatigue testing at elevated temperatures, while the extension of the Corrosion Laboratories is called for by the great demands which are made on the Association to-day for further work in the field of corrosion, including stress corrosion.

Simultaneously with the re-planning and extension of its laboratories, the Association has recently reconsidered thoroughly its field of work and the organisation of its activities in relation to the needs of the industry it represents.

The non-ferrous metals industry is a varied group of industries comprising producers, manufacturers and users of the main industrial metals other than iron and steel. It includes a large number of firms with well-equipped and staffed research laboratories, and a number of small firms with little or no research facilities or technical staff of their own. The needs of the members, therefore, vary widely, and the Association's policy is first to carry out long-term researches designed to provide a basic understanding of the factors involved in the fabrication or service life of the materials in question, and secondly to help members, particularly the smaller ones, in the utilization of existing metallurgical knowledge in dealing with their immediate difficulties and in raising the technical efficiency of the industry.

The long-term research programme requires primarily a first-class scientific staff with all the equipment and facilities necessary for their work, but equally important is an adequate knowledge of the technology of the industry. The Association's staff is not by itself in a position to conceive and formulate the long-term projects which should be investigated, and for this purpose several industry research committees have been established consisting of the most highly qualified men of science available in the different sections of the industry. These committees are responsible, in co-operation with the staff, for the formulation of the research programme and for the appointment of sub-committees of industrial technicians, intimately acquainted with each particular problem, for the guidance and advice of the Association's staff in carrying out the work. These committees, of course, do not direct the research work in detail, which responsibility lies with the Director and senior staff, but serve to keep the staff fully informed on the industrial experience which is helpful during the course of the investigation.

At the other extreme, the problems of the small firm, which frequently needs information more than research, are dealt with by the Liaison Department with the backing of a comprehensive Library and Information Service. The Association's liaison staff maintains contact with the industry and with the research work in progress in the Association and elsewhere, and offers confidential service which is greatly appreciated by the small member in dealing with certain *ad hoc* problems which can be solved in the light of existing knowledge or which require only a small amount of work for their solution. If a problem entails a considerable amount of investigation, this can only be done either by including it in the general research programme or by putting in hand a special research at the cost of the member, the results of which must be made available to all members.

In general, therefore, in the research field the Association's programme of objective fundamental work is intermediate between the purely fundamental work unrelated to specific industrial problems which is proper to the universities, and the more *ad hoc* researches on manufacturing problems which are carried out in the research departments of the larger industrial concerns.

FOURTH INTERNATIONAL CONGRESS FOR MICROBIOLOGY

UNDER the presidency of Dr. Thorvald Madsen the Fourth International Congress for Microbiology was held in Copenhagen during July 20–26. It was attended by more than 1,100 delegates from some thirty-five countries, including a strong representation of more than two hundred persons from the British Isles.

The scientific work of the Congress was divided into nine sections which were concerned with: general microbiology, presidents, Sir Alexander Fleming (Great Britain) and Dr. J. Trefouël (France); medical and veterinary bacteriology, president, Dr. G. Ramon (France); viruses and virus diseases, president, Dr. Carl Kling (Sweden); serology and immunity, president, Prof. Th. Thjøtta (Norway); variation and mutation in micro-organisms, president, Dr. A. F. Blakeslee (United States); plant pathology and mycology, president, Prof. Johanna Westerdijk (Holland); soil and water microbiology, president, Dr. S. A. Waksman (United States); dairy and food microbiology, president, Dr. R. Burri (Switzerland); and industrial microbiology, president, Prof. A. J. Kluyver (Holland). There were, in addition, the four following: general sessions dealing with assimilation of carbon dioxide, Dr. C. H. Werkman (United States); viruses in general, Mr. F. C. Bawden (Great Britain); yeast in modern genetics, Prof. Ø. Winge (Denmark); and antibiotics and life, Dr. S. A. Waksman (United States).

More than three hundred papers were presented at the various sections, interest concentrating principally on the discussions concerning antibiotics—with particular reference to penicillin and streptomycin—diphtheria, pertussis, pathogenic streptococci, tuberculosis, brucellosis, poliomyelitis and influenza, the mechanism of infection and immunity, the physical and chemical investigation of antigens and antibodies, bacteriophage, induced mutation, virus diseases of plants and phytopathogenic fungi, soil ecology, micropopulation and nitrogen fixation, food poisoning, bacteriology of dairy products, brewing and fodder yeast production.

In connexion with antibiotics, Dr. P. M. D'Arcy Hart described the bacteriostatic action of licheniformin, derived from a strain of *Bacillus licheniformis*, against a number of Gram-positive bacteria including *M. tuberculosis*, and directed attention to the fertile field for exploration among the aerobic spore-formers. The classification of this group has now been reduced from its former chaotic state by the taxonomic studies of Nathan R. Smith, Ruth E. Gordon and F. E. Clark in the United States and of T. Gibson in Great Britain, which have placed nomenclature on a sure foundation. Dr. C. H. Andrewes and Dr. Forrest Fulton reported the setting up of a unit for the study of common colds in the buildings of the Haward Hospital, Salisbury, which has been planned for a long-term research project. Attempts are being made to cultivate the exciting factor, which is tentatively presumed to be a virus, or to reproduce the disease in some convenient animal. The development of these researches will be awaited with much interest.

Dr. A. Felix contributed a paper on the nature of bacteriophage. Although the view is held by most bacteriologists that bacteriophages are bacterial viruses, he thought that the facts could be explained with less strain on the imagination if we assume that bacteriophages are not separate biological entities and that their nature is determined by the specific antigenic substances from which they are derived. In the same section (III) Dr. W. I. B. Beveridge directed attention to the similarity of the viruses of mumps and influenza with regard to their hæmagglutination activity, growth in chick embryo and size of virus particles; while in Section IV Dr. F. Kauffmann described a diagnostic schema for the *coli* group based on antigenic features. He expressed the view that the taxonomy of the Enterobacteriaceæ should start with type-diagnosis based on serological features and that the old classification within the *coli* group, based on fermentation reactions, differentiating *B. coli commune*, *B. coli communior*, *B. acidi lactici*, etc., was obsolete.

With so much material for notice and for comment it is difficult to make selection of a few salient papers, but those on phage typing of *Shigella sonnei* (E. Hammarström), "Les Hyphomycètes prédateurs des larves de Nématodes parasites des plants et des mammifères" (R. Deschiens and L. Lamy), Dr. C. E. ZoBell's paper with reference to the depth at which bacteria are active in marine bottom deposits and the series of papers dealing with the production of fodder yeast are perhaps deserving of especial mention, which applies also to the technical excellence of Dr. R. W. G. Wyckoff's photographs illustrating his paper on electron microscopic study of the antigen-antibody reaction and to Dr. J. Comandon and Dr. P. de Fonbrune's film illustrating "Champignons prédateurs de Nématodes du sol".

While plant pathology and mycology were well catered for, one would have wished to see a sub-section of the Congress devoted to medical and veterinary mycology, a subject of growing importance and to which notable contributions have recently been made by the employment of new techniques and methods of research; in this connexion the names of N. F. Conant and C. W. Emmons in the United States and of J. T. Duncan in Great Britain come readily to mind. One may hope that at the next International Congress for Microbiology this important branch of mycology, and also the field of protozoology, will receive due recognition.

Apart from the general programme of the scientific work of the Congress a number of committees carried out duties of considerable importance. The Permanent International Commission for the Organisation of Congresses drafted new statutes for the International Association of Microbiologists (I.A.M.B.) which had become necessary on account of the relationship that the Association bears to the International Union of Biological Sciences (I.U.B.S.), of which it is now a microbiological section and is thus in organic association with the International Council of Scientific Unions (I.C.S.U.) and with the Division of Natural Sciences of the United Nations Educational, Scientific and Cultural Organisation (U.N.E.S.C.O.). Meetings of the Permanent International Committee on Bacteriological Nomenclature and of the Judicial Commission on Bacteriological Nomenclature were also held at which the "Proposed Bacteriological Code of Nomenclature" edited by R. E. Buchanan and R. St. John-Brooks was presented for approval and for subsequent publication in the *Proceedings* of the Congress.

Action was also taken by the Nomenclature Committee and the Permanent Commission in welcoming the proposal that the Centre de Collection de Type Microbiens, Lausanne, Switzerland, under the direction of Prof. Paul Hauduroy, should be associated with the International Association of Microbiologists, both with regard to the preparation of a "World Catalogue of Strains of Micro-organisms" and also in the formation of an International Federation of Culture Collections of Micro-organisms. These matters had already received the support and approval of U.N.E.S.C.O., and a small *ad hoc* Commission of the Nomenclature Committee of the Association was formed under the chairmanship of Prof. A. J. Kluyver for overall advice and the administration of any grants-in-aid that might in future be allocated.

A meeting of the *Salmonella* Sub-committee also took place under the chairmanship of Dr. F. Kauffmann. A new and revised report of the work of the *Salmonella* Sub-committee was presented for publication in the Congress *Proceedings*, and the sub-committee was reconstituted under the name of the "Enterobacteriaceæ Sub-committee" so as to include the consideration of problems dealing with *Shigella* and the *coli* group. New sub-committees of the Nomenclature Committee were also constituted dealing with the immediate study of the taxonomy and nomenclature of *Streptococcus*, *Clostridium* and *Mycobacterium*, and for the general outline classification of Schizomycetes to be considered at the next Congress. A meeting of a committee for Phage Typing, to which representatives from fourteen countries had been invited, was held under the chairmanship of Dr. A. Felix.

It was, perhaps, inevitable that the subject of biological warfare should obtrude itself at a congress of this nature, and the matter being raised at the meeting of the International Commission the following resolution was drafted for presentation at the plenary session of the Congress, where it was afterwards passed by acclamation:

"The Fourth International Congress for Microbiology joins the International Society of Cellbiology in condemning in the strongest possible terms all forms of biological warfare. The Congress considers such barbaric methods as absolutely unworthy of any civilized community and trusts that all Microbiologists throughout the world will do everything in their power to prevent their exploitation."

An invitation from the Brazilian Government to hold the Fifth International Congress for Microbiology in Rio de Janeiro in the latter part of 1950 was presented at the meeting of the Permanent Commission by the chief of the Brazilian delegation to the Congress—Dr. H. C. de Souza Araujo. This invitation was accepted by the members present with applause and was afterwards ratified at the plenary meeting of the Congress.

Apart from the exchange of scientific knowledge and the exploration of the ever-widening horizons of research, one of the most important functions of international congresses of this kind is the formation of fresh personal contacts and the renewal of old associations and friendships. This was peculiarly applicable to the present occasion when, owing to the brutal intervention of global war, nearly eight years had passed since a similar concourse had gathered in New York City under the shadow of a world catastrophe. The social side of the Congress's activities, which included much public and private entertainment, was an unqualified success, and it speaks much for the Danish Organising Committee, its general secretary, Dr. M. Björneboe, and the many friends of the Congress that their efforts were so completely vindicated. At the end of the week the delegates returned to their scattered homes with happy recollections of good fellowship, of high endeavour and of successful achievement.

RALPH ST. JOHN-BROOKS

OBITUARIES

Dr. H. T. Calvert, M.B.E.

WITH the death from heart failure of Harry Thornton Calvert in his seventieth year on September 23, there has passed away a leading authority on the science and technology of water supplies, sanitation, and the prevention of pollution of rivers and underground water resources. He was born in Leeds, Yorkshire, on May 3, 1878. Following his early education he proceeded to the Yorkshire College (now the University of Leeds), to study in the honours school of chemistry. Calvert was soon recognized as a student of more than average ability. On graduation in 1898, he was at once awarded an 1851 Exhibition and went to Leipzig, where he remained until 1901 and took the Ph.D. degree.

On return from Germany, Calvert served for a short time as a demonstrator under the late Prof. Arthur Smithells at the University of Leeds, before taking up an appointment as chemist to Messrs. Reckitt and Sons, of Hull, with which firm he gained valuable experience in chemistry applied to industrial problems. In 1903, he moved to become chemist to the West Riding of Yorkshire Rivers Board, a joint committee of local authorities which had been set up to administer the Rivers Pollution Prevention Acts. This change in his scientific activities marked the beginning of his interest in the problems of water supply and sanitation generally, a subject which remained his chief interest throughout the rest of his career.

At that time Dr. Maclean Wilson was chief inspector of the Rivers Board. Calvert and he were ideal partners in guiding this important work. They were not inspectors in the narrow sense of the word; but studied in detail the problems of treatment and disposal of sewage and the manufacturing processes in the West Riding which gave rise to the discharge of polluted waste waters. As a result they fully recognized the difficulties to be overcome, and devoted their energies largely to guiding and assisting managers of sewage disposal works and manufacturers in solving their problems. In consequence, the work of the Rivers Board reached a high standard and set an example to the rest of the world. Wilson and Calvert collaborated in writing the book "Trade

Waste Waters: Their Nature and Disposal", which has long been the authoritative work on this subject. It was while he was with the Rivers Board that Calvert was awarded in 1915 the D.Sc. degree of Leeds.

In 1920 Calvert moved to London to take up a new appointment as chemical inspector of the Ministry of Health, a post which gave him wide scope and in which he was eminently successful. When in 1927 the Department of Scientific and Industrial Research set up a water pollution research organisation, Calvert was the obvious choice as director of research, and he undertook this responsibility in addition to continuing his work for the Ministry of Health. He did not believe in rapidly developed schemes of a grandiose character, but in steadily building up on a sure foundation. This policy he followed in guiding the work of the Water Pollution Research Board in excellent partnership with every member of the Board, which was under the chairmanship of Sir Robert Robertson. By 1939, the research organisation had several outstanding achievements to its credit, including a comprehensive survey of the River Tees, an investigation into the effects of discharges of sewage into the River Mersey in relation to problems of navigation, improvements in methods of treatment of sewage, and the development of practicable methods of dealing with the problems of reducing pollution by such trade waste waters as those from beet sugar factories, milk depots, cheese and butter factories, to mention only a few items.

Calvert was recognized as an authority in his field not only in Great Britain, but also throughout the world; and he had close friendship with many professional colleagues on the Continent and in the United States. In addition to his many papers and addresses in Great Britain, including a Chadwick Public Lecture in 1926, he accepted an invitation in 1939 to give the Sedgwick Lecture in the following year at the Massachusetts Institute of Technology, but unfortunately was prevented by the outbreak of war from delivering the lecture. In 1944 he received the Kenneth Allen Award of the American Federation of Sewage Works Associations.

He took a keen interest in the work of the Institute of Sewage Purification, of which he was president in 1927, 1928 and 1939, and was a member of the Council of the Institute for many years. Calvert was also a prominent fellow of the Royal Sanitary Institute, and the Institution of Sanitary Engineers, a professional associate of the Institution of Water Engineers, a member of the Society of Chemical Industry, and a fellow of the Royal Institute of Chemistry and of the Chemical Society.

During the First World War, from 1916 until 1919, he was with the Department of Explosives Supply of the Ministry of Munitions, and his work was recognized by the award of the M.B.E. On the outbreak of war in 1939 he was seconded to the Ministry of Supply as deputy controller of sulphuric acid, which post he retained until his retirement early in 1947.

Calvert was a man of kind heart and generous disposition, with a marked ability in quietly getting boards, committees and staff working together amicably and efficiently, and all who worked with him came to know him as a close friend. He was devoted to his family. The death of his wife in 1937 was a severe blow to him. All three of his sons have had distinguished university careers, one in physics, a second in chemistry and engineering, and a third in arts and law. A. PARKER

Surgeon Rear-Admiral C. M. Beadnell, C.B., K.H.P.

SURGEON REAR-ADMIRAL CHARLES MARSH BEADNELL, who died at Petersfield, Hampshire, on September 27, was president of the Rationalist Press Association, Ltd., and the author of several scientific books. Born at Rawalpindi in 1872, he was educated at Cheltenham College; and after studying medicine at Guy's Hospital he joined the Navy as a surgeon in 1896. He came to intellectual maturity while the great evolution controversy was still raging, and fell under the spell of Huxley. He became an ardent rationalist, and although service conditions somewhat restricted the propagation of his views, he frequently contrived to give lectures on evolution to the 'lower deck'. On one occasion the commander-in-chief attended, and instead of administering the expected rebuke, he merely remarked that he had enjoyed the lecture very much; but, he added: "On second thoughts, Adam and Eve are good enough for me".

Beadnell's enthusiasm for science led him to buy, out of his own earnings, an X-ray apparatus, the first to be used in the Royal Navy. In the American-Filipino War he collected specimens of bullet injuries to skulls, when he found that the Filipinos did not bury their dead. During the Boer War, when pronounced medically unfit for front-line service he broke away from a hospital train and tramped all night to take part in the fighting at Graspan. The *Titanic* disaster stimulated him to invent an air-distensible waistcoat.

In 1922 Beadnell represented the Navy and Army Medical Departments at the International Congress of Surgeons at Washington. On his return he became head of Chatham Hospital, retiring at his own request four years later. Retirement brought him the opportunity to devote much of his time, and his gift for simple exposition, to general science and the cause of rationalism. The fire kindled in the great days of Huxley never died; but perhaps the strongest influence was that of W. K. Clifford. His intellectual integrity was as unquestionable as his physical courage, but he was no fanatic. In a revealing letter, written the day before he died, he declared that Clifford had brought him from "the respectable sphere of Agnosticism to that of Atheism; not of the blatant type, but of a convinced, quiet kind in which I would not argue in public on religious questions, if other officers I knew to be religiously persuaded happened to be present". He became a director of the Rationalist Press Association and succeeded Lord Snell as president in 1940. Among his publications were: "Evolution of Speech", "Picture Book of Evolution (after Dennis Hird)", "Origin of the Kiss", "Dictionary of Scientific Terms" and "An Encyclopædic Dictionary of Science and War".

Prof. Paul Guthnick

PROF. PAUL GUTHNICK was born at Hitdorf am Rhein on January 12, 1879. After studying under Küstner at Bonn, he became an assistant at the Berlin Observatory in 1901. After three years at the Bothkamp Observatory, he returned to Berlin in 1906 and moved steadily up in the scale of Observatory and University posts until 1921, when he succeeded Hermann Struve as professor of astronomy in the University of Berlin and director of the University Observatory at Berlin-Babelsberg. In 1927 he was elected an associate of the Royal Astronomical Society.

Guthnick's chief work lay in stellar photometry, and he was particularly successful in developing photo-electric methods, carrying out many pioneer investigations. He worked largely with stars of very small and irregular variations, but he also studied Mars and the satellites of Jupiter and Saturn. He applied photo-electric methods to measure the colour indices of stars, notably Nova Aquilæ 1918. His original and somewhat unorthodox outlook was reflected in theories that he put forward for several classes of variable stars.

He died in hospital in Berlin on September 6.

WE regret to announce the following deaths:

Prof. A. T. Cameron, professor of biochemistry in the University of Manitoba, author of well-known text-books on biochemical studies, on September 25, aged sixty-five.

Prof. J. Masson Gulland, F.R.S., Sir Jesse Boot professor of chemistry in University College, Nottingham, on October 26, aged forty-nine.

Prof. F. E. Lloyd, emeritus professor of botany in McGill University, Montreal, aged seventy-nine.

NEWS and VIEWS

Nobel Prize for Physiology and Medicine, 1947: Prof. Bernardo A. Houssay, For.Mem.R.S.

ONE part of the Nobel Prize for Physiology and Medicine for 1947 has been awarded to Prof. Bernardo A. Houssay, recently professor of physiology in the University of Buenos Aires (see *Nature*, November 23, 1946, p. 739). Before Houssay took up his investigations on the influence of the pituitary gland on carbohydrate metabolism, it was confidently believed that the posterior part of the gland was thus concerned. More than twenty years ago, Houssay and his collaborators showed without question that the anterior portion of the gland is of importance in this connexion, and their demonstration that the dog from which both the pituitary gland and the pancreas were removed survived much longer than the animal from which the pancreas alone was removed was of outstanding importance in demonstrating that carbohydrate oxidation can occur in the complete absence of insulin. It thus became clear that insulin enhanced glucose utilization in the body, while anterior pituitary secretions inhibited it; and in keeping with this, Houssay and others were later able to show that extracts of the anterior lobe exert a diabetogenic action in the normal dog.

Prof. Carl F. Cori and Mrs. Cori

THE other part of the Nobel Prize has gone to Prof. Carl F. Cori and Dr. Gerty T. Cori, of the Washington University School of Medicine. Prof. and Mrs. Cori have pursued a line of investigation which has now to some extent merged with that of Houssay and his colleagues. The Coris have investigated for the past twenty years or so the changes undergone by the glucose molecule, and the enzymes responsible for the changes, in the processes of glycogen formation and breakdown in the animal body. In 1939 they were able to prepare for the first time an enzyme which catalysed the synthesis *in vitro* of a polysaccharide resembling starch and glycogen. More recently they have examined the action of the enzyme hexokinase, responsible for the phosphorylation in the body of glucose to glucose-6-phosphate at the expense of the conversion of adenosine triphosphate to adenosine diphosphate. The Coris have been able to show that anterior pituitary extract and insulin exert antagonistic actions on this enzyme system *in vitro*, anterior pituitary extracts depressing hexokinase activity, and insulin neutralizing this depression. This observation goes a long way to explain in terms of enzyme systems the action of some of the hormones the physiological investigation of which has been the pursuit of Houssay and his collaborators.

Physiology at St. Bartholomew's Hospital Medical College: Prof. K. J. Franklin

BY the appointment of Dr. K. J. Franklin, acting director of the Nuffield Institute for Medical Research, Oxford, to the professorship of physiology in the University of London tenable at St. Bartholomew's Hospital Medical College, Oxford loses a scholar who has served the University for many years, and 'Bart's' reclaims a former student. After serving in the R.F.A. in the First World War, Franklin went as a classical scholar to Hertford College, Oxford. He turned to biology and medicine, gaining the Welsh Memorial Prize for anatomical drawing in 1920, and first-class honours in animal physiology the following year. After a period as lecturer in Oxford and in London, he returned to Oxford in 1924 as fellow of Oriel and demonstrator in the Department of Pharmacology, but a year later was off again as a Radcliffe Travelling Fellow, which appointment he combined with an assistant professorship of physiology in the University of Michigan. He shared the Radcliffe Prize for research in 1933, and was dean of the Oxford Medical School from 1934 until 1938, and acting dean during the Second World War.

Apart from teaching, of which Franklin has done a great deal in Oxford (his pupils number more than a hundred), he divided most of his time between the experimental study of the circulation in general and veins in particular, and the history of medicine with particular reference to the circulation. In the latter studies Franklin's early classical training served him in good stead. When the Nuffield Institute of Medical Research was established in 1935, Franklin accompanied Prof. J. A. Gunn from the Department of Pharmacology as the Institute's assistant director. Here he turned his attention to the study of the circulation by cine-radiography, a technique which he studied under Janker in Bonn. In this work he collaborated with Dr. A. E. Barclay and the late Sir Joseph Barcroft; their studies of the fœtal circulation have already been published. More recently Dr. Trueta joined the team, and their study of the renal circulation has just been published by Basil Blackwell of Oxford. This work has provided a very useful technique that will no doubt be applied to other organs, and has also given important physiological information regarding the mechanism of the circulation. Since Prof. Gunn's retirement, Franklin has been acting director of the Institute. No doubt Franklin will continue similar studies in London when he is able to gather together the elaborate equipment needed. In the interval of doing this, we look forward to a continuation of his publications on the history of physiology.

Botany at McGill University: Prof. Nicholas Polunin

THE recent appointment of Dr. Nicholas Polunin to the Macdonald professorship of botany in McGill University, Montreal, was an especially suitable one in that arctic botany has long been one of Dr. Polunin's chief interests and he has devoted special attention to the flora and ecology of north-eastern Canada. Since 1930 he has made several expeditions inside the Arctic Circle, ranging from Lapland and Spitsbergen in the east through Greenland to the territories covered by the Canadian Eastern Arctic Patrol. The Canadian Department of Mines and Resources has sponsored his work on "The Botany of the Canadian Eastern Arctic" to be published in four parts, three of which have already appeared.

Dr. Polunin went to Christ Church, Oxford, with an open scholarship in natural science in 1927. He graduated in the Final Honours School of Natural Science in 1932 and was awarded a Goldsmith's Senior Studentship. Later he received the degrees of D.Phil. and D.Sc. In 1933 he was awarded a Henry Research Fellowship at Yale University, of which he holds the degree of M.S. (1934). Returning to Oxford he was elected to a senior research scholarship at New College, during the tenure of which he was also research associate at Harvard (1936–37). Since 1938 he has been curator of the Fielding Herbarium, Department of Botany, Oxford, and in 1939 was elected University demonstrator. In 1946 he was elected to a research fellowship at New College. With the cessation of hostilities, fieldwork again became possible, and in 1946 Polunin was granted leave of absence from Oxford in order to allow him to accept a visiting professorship at McGill and take part in further expeditions to the north-east of Canada, which he has done during the summers of 1946 and 1947.

Brigadier D. P. J. Kelly

BRIGADIER D. P. J. KELLY has recently retired from the post of controller of the Royal Army Educational Corps. Born in London in 1887 and educated at the University of Cambridge, he was commissioned into the Connaught Rangers in 1915 and was gazetted as a captain in the Army Educational Corps in 1920. Following eleven years of service in India, he returned home in 1940 and was appointed command education officer in Scottish Command. In this post he was responsible for the introduction of the war-time scheme of education, and the friendly relations which continue to exist between the Army and the Scottish universities, the Scottish Education Department and the voluntary bodies engaged in educational work in Scotland, owe much to his ability and personality. Selected as controller in 1944, at a time when the educational scheme for the release period was being planned, he worked in the closest co-operation with Sir Philip Morris. More recently, he has been actively engaged under Major-General Cyril Lloyd in planning the future organisation of the Royal Army Educational Corps.

Scientific Development in China

THE members of the Chinese Association for the Advancement of Science, the Natural Science Society of China, the Chinese Astronomical Society, the Chinese Meteorological Society, the Chinese Geographical Society, the Chinese Zoological Society and the Chinese Anatomical Society, gathered at their joint annual conference in Shanghai during August 30–September 1, passed resolutions, the substance of which is printed below, on the control of atomic energy and on the development of scientific research in China.

(1) Atomic research. Chinese scientific workers feel that the probing into the mysteries of atomic energy, like scientific research work in all other fields, should have as its objective the promotion of human welfare. The energy of the atomic nucleus was successfully released at a time when the democracies were locked in a life-and-death struggle with the totalitarian States; and quite naturally it was taken advantage of in the making of weapons of war. This is unfortunate for atomic energy and also for scientific research. Now that the War has been concluded and the democracies are endeavouring to bring about world co-operation, atomic research should be freed from its close-guarded secrecy, to be directed towards the advancement of the application of other achievements in atomic research.

(2) Scientific research in China. The Chinese as a race are still facing starvation and other acute shortages in this atomic age, backwardness in the development of science being one of the causes. The significance of such development is in its power to raise proportionately the standard of living. Sufficient emphasis has not hitherto been given to the fundamental sciences; and a mature status in scientific work will not be acquired suddenly by the importation of a few instruments for atomic studies. Foundations must be laid first by the strengthening of the physical equipment for science education and by extending adequate facilities and stable living conditions to teaching and research personnel in China. What is more important, China should adopt a definite and long-range plan for the development of scientific undertakings, with the necessary budgets to carry it out to the fullest extent. If science is to serve as an important contributing factor in the reconstruction of China, it must be made to stand on firmer ground; scientific development cannot be bought ready-made.

Chinese Association for the Advancement of Science

THE Chinese Association for the Advancement of Science (formerly the Science Society of China) held its twenty-fifth annual meeting during August 30–September 1 at the Academia Sinica and National Medical College of Shanghai, Shanghai, with the Natural Science, Astronomical, Meteorological, Geographical, Zoological and Anatomical Societies of China. Mr. H. C. Zen presided over the meeting; Dr. W. H. Wong discussed secrecy in scientific research and its effects, and Dr. K. C. Chu emphasized the utilization of scientific knowledge for peace. Besides the presentation of papers in different sections, there were discourses on "Atomic Energy and Peace", "Improvement of Scientific Education in China", and other public lectures.

Home and Factory Power Exhibition

A SMALL exhibition entitled "Home and Factory Power" was opened in the main hall of the Science Museum by Lord Citrine, chairman of the British Electricity Authority, on October 21. The exhibition will remain open until the end of January and is intended to show visitors that it is their personal responsibility to avoid the overloading of power stations and gas plants during the peak hours. In his opening remarks, Lord Citrine anticipated a five-year shortage of electrical plant in spite of the fact that the manufacturers are attempting to double their 1938 output. Consequently, with electric power demands already 60 per cent above the 1938 level, and the effects of the war-time lag in extensions and maintenance still to be caught up, there are bound to be power cuts in this and succeeding winters unless the domestic consumer is much more careful. In the exhibition this point is brought home by a series of working models. Thus, by pressing a button the visitor brings on an electric fire but at the same time stops the operation of a model workshop. The workers sit down to wait until the fire is switched off again. An illuminated label at the same time stresses the need to avoid the peak load hours of 8–10 a.m. and 4–6 p.m. The loads taken by various domestic gas and electric appliances are shown by a colourful series of panels, which also suggest how to make reasonable savings without undue austerity.

American Institute of Physics

MR. CLEVELAND NORCROSS, formerly executive secretary of the Office of Scientific Research and Development, the official organisation which co-ordinated American scientific work during the War, has been appointed to the newly created post of assistant director of the American Institute of Physics; Dr. H. A. Barton continues as director of the Institute. The administrative change has been necessitated by the enormous increase in the administrative burdens of the Institute, largely due to the continued increase in the number of physicists (the number has trebled in the past ten years, but which is by no means sufficient yet to meet the demands of industry, government research and teaching establishments), and to the growing recognition by the general public of the part that physics does and should play in industrial and national progress. The director will continue to be responsible to the governing board for the general supervision of the Institute, but will be primarily responsible for matters of policy and relations between physical organisations and allied bodies. Advertisement, appointments, public relations, and attention to matters affecting the member societies of the Institute will be the main concern of the assistant director.

International Scientific Film Association

AT a congress in Paris during October 2–9, arranged jointly by the Institut de Cinématographie Scientifique and the Scientific Film Association, it was decided to form an International Scientific Film Association. A provisional constitution was agreed by the delegates from twenty-two countries, under which the Association will have a main meeting each year, but between these main meetings the affairs of the Association will be managed by a council comprising five officers and seven other members. The Council for the present year is: *President*, M. Korngold (Poland); *Vice-Presidents*. J. Maddison (Great Britain) and Prof. Pinto (Brazil); *Hon. Secretary*, M. Jean Painlévé (France); *Hon. Treasurer*, M. Sallaz (Switzerland); and one delegate each from Australia, Austria, Belgium, Canada, Czechoslovakia, Malaya and Mexico. The Association will be concerned with all aspects of scientific film matters. The exchange of information through the office of the Association (which will be established in Paris at an early date) will begin at once on scientific and technical films that are already available for exchange, on methods of appraisal, and on customs regulations on the exchange of films. Concurrently with each annual meeting of the Association, which will be held in different countries by invitation, there will be an examination of new scientific and technical films. The 1948 Congress is to be held in Great Britain in October; arrangements are being put in hand by the Scientific Film Association of Great Britain, 34 Soho Square, London, W.1.

Archæological Work in Greece

DURING the war years little archæological excavation was possible in Greece; but here and there minor discoveries were made, and these are summarized in the annual report of the Committee of the British School of Archæology at Athens. It appears in the *Journal of Hellenic Studies*, 64 (1944), and carries the story down to 1945. There are some illustrations, including a portion of a tholos tomb discovered near Knossos.

University of London: Appointments

THE following appointments in the University of London have been announced: Prof. Henry Barcroft, since 1935 Dunville professor of physiology in the Queen's University of Belfast, to the University chair of physiology tenable at St. Thomas's Hospital Medical School as from January 1, 1948; Dr. T. D. Day, to the University readership in pathology tenable at St. Thomas's Hospital Medical School; Dr. Russell Fraser, to the University readership in medicine tenable at the British Postgraduate Medical School; Dr. C. J. O. R. Morris, to the University readership in chemical pathology tenable at the London Hospital Medical College.

The title of professor emeritus of mining geology in the University has been conferred on Prof. W. R. Jones on his retirement from the chair of mining geology at the Imperial College of Science and Technology.

The degree of D.Sc. has been conferred on the following: Mr. Sachindranath Dasgupta (Imperial College of Science and Technology); Mr. Norman Davy; Mr. R. L. Knight (Wye College); Mr. W. S. Martin (Imperial College of Science and Technology); Prof. Claude Rimington (University professor of chemical pathology, University College Hospital Medical School); Mr. Yung Chow Wong (King's College).

Announcements

A JOINT conference of the Midland Branch and the X-ray Analysis Group of the Institute of Physics to discuss "The Structure and Physical Properties of Metals" will be held at Birmingham during November 20–21. Further particulars of the meeting, which is open free of charge to all who are interested, can be obtained from J. N. Kellar, honorary secretary of the X-ray Analysis Group, Crystallographic Laboratory, Cavendish Laboratory, Cambridge.

THE annual conference of the Agricultural Section of the Association of Scientific Workers will be held during November 8 and 9 at Gas Industry House, Hyde Park Corner, London. Sir John Fryer, secretary of the Agricultural Research Council, will address the first session at 3 p.m., which is open to all agricultural scientific workers.

DR. WILLIAM A. HAMOR, of the Mellon Institute, Pittsburgh, has been appointed editor of the Chemical Monographs of the American Chemical Society. This series of reference volumes now numbers 105.

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications

A New Adsorption Apparatus and the Separation of Aspartic and Glutamic Acid

THE need has been felt in this laboratory for a simple apparatus capable of recording eluate concentrations by chemical means. The main features of an apparatus made for this purpose are: a syringe to force the solution through the adsorption column, from which a flexible canula and a capillary-drop tip convey the eluate to a rotating metal drum, on which a filter paper is fastened. The drop tip is pushed along the lowest generatrice of the cylinder and at regular intervals lifted up to the paper, where a drop of the eluate is deposited. The device for this lifting (not shown in Fig. 1) is operated from a cog-wheel on the left end of the drum. Syringe, drum and drop tip are driven synchronously by an electric motor through a system of cog-wheels and threadworms.

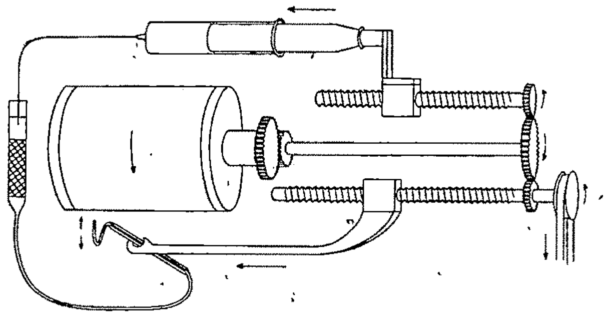

Fig. 1. SCHEMATIC DRAWING

The paper can be either used directly, when dyes are analysed; or prepared in advance with some reagent which, during the run or after some special treatment, gives a colour with the eluted substances; or afterwards sprayed with a suitable reagent solution. After development, if this is needed, the colour intensities of the spots are compared subjectively with each other and with spots obtained from solutions of known concentration.

The model apparatus is built in a compact manner on a metal plate, 140 mm. × 310 mm. The drum is 120 mm. long and 75 mm. in diameter. Twenty spots are obtained for each revolution of the drum, to which corresponds a 10 mm. displacement of the drop tip. About ten revolutions can be run, which means a total of about 200 spots, that is, with a 20 ml. syringe one obtains one analysis for each 0·1 ml. As the quantity deposited on the paper is about 3 μl., it is seen that the major part of the eluate will flow down from the drop tip, and if the liquid is collected here, a correction can be made for the substance lost in the spots. As the next step I intend to construct a synchronous eluate collector, which can change the eluate tubes for, say, each fourth spot. (A similar apparatus has been described by Moore and Stein[1].)

The apparatus is simple and relatively inexpensive, it is very convenient and omits much work with continuous interferometer readings or excessive eluate fractionating and analysing[2,3]; but one must know some good spot test reaction for the substances investigated. A great advantage over physicochemical methods is that this apparatus works independently of the solvent, which can be changed during the run without affecting the spot reactions. Likewise, other substances can be present without harm, provided they do not give a colour reaction. Sometimes the chemical method will make it possible to observe simultaneously the individual concentrations of two or more substances.

In order to test the apparatus, I studied the behaviour of the two dicarboxylic amino-acids on a column of the ion exchange resin 'Amberlite IR—4'. It was found that, after adsorption from an aqueous solution, both of them were eluted with N hydrochloric acid at a high rate, obviously by being displaced by the strong acid front. With smaller concentrations the aspartic acid was overtaken by the hydrochloric acid front, while the glutamic acid was still more or less displaced. The best results were obtained with about $N/100$ hydrochloric acid, but even here the separation was not complete. Better results were obtained with acetic acid, which in a concentration of 0·05 per cent gave a fairly good separation. Two control runs were made to test the separation:

(1) About 3 mgm. each of the two amino-acids were adsorbed in a glass filter on 630 mm.^{3} of 'Amberlite IR—4B', pretreated with N hydrochloric acid and water[4]. The elution was performed from a 10 ml. syringe, which gives 1·4 ml. for each revolution of the drum, that is, one spot for each 0·07 ml. First, 11 ml. of 0·05 per cent acetic acid were forced through to elute the glutamic acid, and afterwards, with a new paper on the drum, 4 ml. N hydrochloric acid to elute the aspartic acid, which comes out too slowly when the dilute acetic acid is used. After the two runs, which lasted for 70 min. and 30 min. respectively with a 10 min. interval between, the papers were sprayed with a ninhydrin solution and heated. During the runs, eluates corresponding to each revolution of the drum had been fractionately collected, and after the development they were poured together in four fractions (see Fig. 2). These were analysed by the micro-Kjeldahl procedure, which gave the following results. (The somewhat high value for aspartic acid nitrogen in this preliminary analysis can be due to a contribution from the resin, when this is eluted with N hydrochloric acid[4].)

RESULTS OF THE MICRO-KJELDAHL DETERMINATION

Fraction	I	II	III	IV
μ gm. nitrogen found	10	302	4	319
Corrected for substance in the spots	10	315	4	332
μ gm. nitrogen calculated	(0)	325	(0)	311

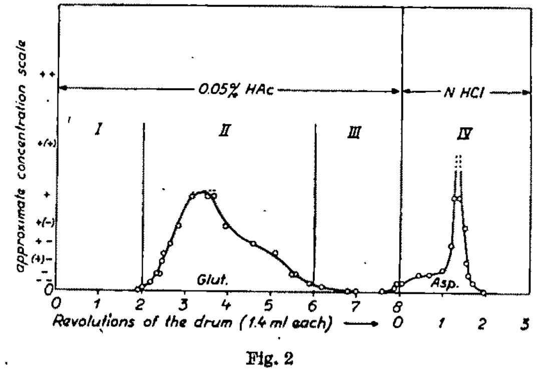

Fig. 2

(2) In another experiment the eluate was divided into two fractions, which were examined by one-dimensional paper chromatography with phenol–0·1 per cent ammonia–coal gas[5]. Also in this manner the effectiveness of the separation was entirely confirmed.

While several methods have been described, using the column procedure with inorganic adsorbents or the batch procedure with 'Amberlite IR-4' for the separation of the two dicarboxylic amino-acids, this method is the first to use an ion exchange resin in flowing chromatography for this purpose.

Note added in proof. While this letter was in the press, I was told that Consden *et al.* are about to publish a similar method.

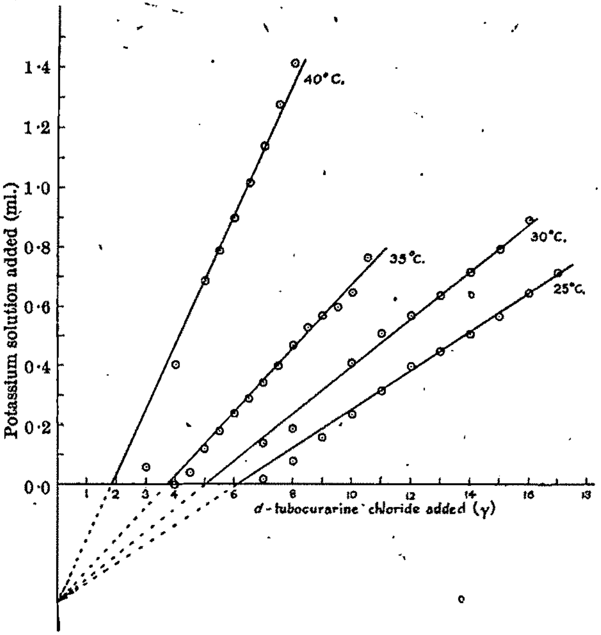
Antagonism Between Curare and the Potassium Ion

IT has been known for some time that a fall of temperature can reverse the motor end-plate blocking action of curare[1]. There seems to be two possible explanations of this strange phenomenon. The simplest hypothesis is to regard the reaction between curare and the receptor as a reversible dissociation which increases with decreasing temperature, a most unusual assumption. Alternatively, we might assume that the curare was being antagonized by some naturally occurring substance (cf. Ing and Wright[2] in this connexion), and that as the temperature was lowered the competition went against the curare. Since Wilson and Wright[3] have shown that potassium antagonizes curare, we investigated this competition quantitatively in order to determine the influence of temperature on the antagonism between added curare and the naturally occurring potassium ions.

Enough curare (*d*-tubocurarine chloride) was added to a slip of rat diaphragm to paralyse to a steady value of 50 per cent. More curare and Tyrode containing 100 times the normal amount of potassium chloride were then very carefully added in such a way as to keep the block steady at 50 per cent. In this way, it was found possible to back-titrate curare with the K^+ ion. The results (see graph) show that at constant temperature curare and potassium are in direct linear antagonism, and that within the limits of experimental error the graphs on extrapolation pass through the vertical axis at a point corresponding to zero potassium concentration in the fluid surrounding the muscle. The point at which each line crosses the horizontal axis is a measure of the dose of curare which causes a 50 per cent block in the presence of the amount of potassium normally present in the bath.

It is clear, therefore, that as the temperature falls, the dose of curare required to cause a 50 per cent block is increased to such an extent by the potassium normally present in the preparation that about three times more curare is required at 25° C. than at 40° C. to give the same effect. We therefore consider that the reversal of the action of curare with a fall of temperature is quantitatively explained by the second hypothesis mentioned above, namely, that curare is competing with naturally occurring potassium ions and that as the temperature is lowered the competition favours the potassium ion. Moreover, it provides an experimental basis for the understanding of the charge-density theory of the relationship between structure and action in drugs with curariform actions[4].



RELATIONSHIP BETWEEN *d*-TUBOCURARINE CHLORIDE ADDED TO A 40-ML. BATH AND THE AMOUNT OF TYRODE SOLUTION CONTAINING 100 TIMES THE NORMAL AMOUNT OF POTASSIUM CHLORIDE REQUIRED TO MAINTAIN THE NEURO-MUSCULAR CONDUCTION IN THE PREPARATION IN A STATE OF 50 PER CENT BLOCK

It is difficult to avoid the conclusion that, before it can block, curare must displace potassium, and that voluntary muscle possesses a powerful positive charge-seeking mechanism.

Hippuric Acid Formation from Glycine and Dibenzoylphosphate

MONOBENZOYLPHOSPHATE and dibenzoylphosphate were synthesized by letting benzoylchloride react with a mixture of silver phosphate and orthophosphoric acid in a way similar to that described by Lipmann[1] in his fundamental work on monoacetylphosphate.

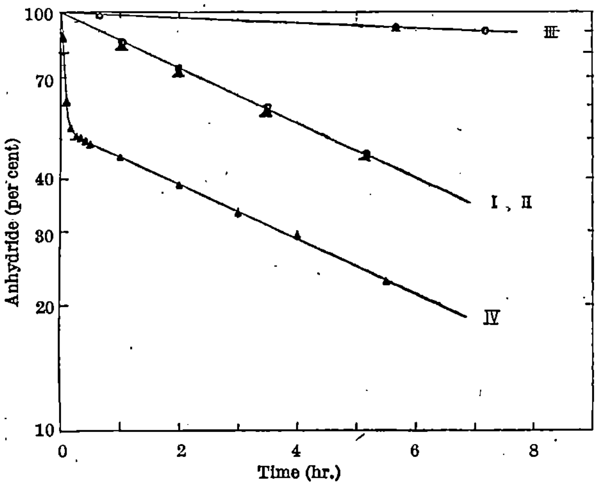
Monobenzoylphosphate has been isolated as the disilver salt, $(C_6H_5CO)\,PO_4Ag_2$; dibenzoylphosphate as the crystalline sodium salt $(C_6H_5CO)_2PO_4Na$. Both compounds undergo spontaneous hydrolysis in neutral aqueous solution. At 37° in $M/30$ phosphate buffer, pH 7·4, sodium monobenzoylphosphate has a half-life time of about 4½ hours. Sodium dibenzoylphosphate is much more stable: half-life about 45 hours under the same conditions. Both react with concentrated hydroxylamine (1 molar) at pH 7·4 to form one molecule of benzhydroxamic acid per anhydride group. The benzhydroxamic acid formed can be detected and determined in the form of its red complex ferric salt (max. absorption 525 mμ) (cf. Lipmann and Tuttle[2]).

At 37°, pH 7·4 monobenzoylphosphate does not react with glycine; however, one of the anhydride groups of dibenzoylphosphate reacts very rapidly with glycine, as can be seen from the following experiment.

The following mixtures were incubated at 37° C.:

(I) 5 ml. $M/15$ phosphate buffer, pH 7·4 + 5 ml. $M/50$ monobenzoylphosphate.
(II) 5 ml. $M/5$ glycine in $M/15$ phosphate buffer + 5 ml. $M/50$ monobenzoylphosphate.
(III) 5 ml. $M/15$ phosphate buffer, pH 7·4 + 5 ml. $M/100$ dibenzoylphosphate.
(IV) 5 ml. $M/5$ glycine in $M/15$ phosphate buffer + 5 ml. $M/100$ dibenzoylphosphate.

Samples were taken from time to time and the anhydride groups determined by the hydroxylamine method. In the accompanying graph, the results for I–IV have been plotted on a logarithmic scale against the time. It is evident that, under the experimental conditions, glycine has no influence on the breakdown of monobenzoylphosphate. The situation is, however, very different for dibenzoylphosphate. In the presence of glycine, half its anhydride groups disappear within a few minutes, and the residual groups break down at the same rate as monobenzoylphosphate.



Acetone-titration showed that NH_2-groups disappear during the reaction; hippuric acid formation has been qualitatively demonstrated by the partition chromatography method[3] using ethyl acetate and water as the two liquid phases.

The reaction can thus be written

$$(C_6H_5CO)_2\,PO_4^- + {}^+NH_3CH_2COO^- = C_6H_5CONHCH_2COO^- + C_6H_5COPO_4^{=} + 2H^+.$$

The corresponding reaction has been observed with ornithine and lysine too.

The present results serve to demonstrate that a peptide linkage can easily be formed by spontaneous non-enzymic reaction, from an amino-acid and a diacylphosphate, under physiological conditions (pH and temperature). It is suggested as a working hypothesis that diacylphosphates or substituted acylphosphates rather than mono-acylphosphates[4,5] could be the intermediary activated state of the carboxyl groups in the peptid-bond synthesis. It can easily be imagined that carboxyl groups of amino-acids, or their precursors, could be activated by phosphate groups bound to other cell constituents; special attention should be given to nucleic acids in view of the idea that they are involved in the protein synthesis[6,7].

It should also be pointed out that Lipmann[8] was unable to find any influence of monoacetylphosphate on the acetylation of sulphonamides, although the role of phosphorylation in the process strongly pointed to an intermediary formation of acetylphosphate. In the light of the results reported above, the failure of added monoacetylphosphate to act as acetylating agent could possibly be explained by assuming that the real phosphorylated agent is a substituted acetylphosphate.

Methionine in Urine

In 1944 Albanese, Frankston and Irby[1] published their hydrogen peroxide – perchloric acid oxidation method for the estimation of methionine in protein hydrolysates and human urine. They stated: ". . . the applicability of the procedure to the urine was established by means of a study which demonstrated that the normal urinary constituents failed to react as methionine. This practice was further justified by the observations that the ingestion of *dl*-methionine by normal individuals resulted in a prompt elevation of the methionine level in the urine, as determined by our method. From a limited series of observations, it has been found that the normal adult (male) on a normal diet excretes 247 to 494 mgm. of methionine daily."

According to Cantarow and Trumper[2], the daily amount of amino-acid nitrogen in the urine ranges from 0·1 to 0·2 gm. Thus a daily output of 35 mgm. of amino-acid nitrogen (equivalent to 370 mgm. of methionine, average value) represents 23 per cent of the total amino-acid nitrogen (equivalent to 150 mgm., average value).

Under the direction of Dr. T. F. Dixon, many attempts were made in these laboratories to isolate the methionine from specimens of both human and pregnant mares' urine. The urines were titrated according to the method of Albanese, when methionine excretion values in the case of human urine came within the stated range. The horse urine averaged

440 mgm. of methionine per litre of urine. All attempts to isolate the methionine were fruitless, and the experiments were abandoned. Interest was revived, however, when Dent[3] showed that the filter-paper chromatography technique could be applied to human urine. He demonstrated the presence of at least two amino-acids of R_F values 0·37 and 0·57 (glycine and alanine ?). No mention was made of methionine, and presumably it was not revealed.

Experiments were then conducted in these laboratories in a further attempt to establish the presence of the amino-acid in normal urine. A pooled sample was divided into two equal parts, and to one was added solid *dl*-methionine, at a concentration of 0·25 mgm./ml. The two specimens were chromatographed side by side and finally treated with ninhydrin. If the claim made by Albanese *et al.*[1] had been correct then the colour intensity of the methionine spot in the sample of urine with added methionine should have been approximately twice that given by the original sample. The two papers were compared, when they were seen to differ by one intensely coloured spot, present in the sample containing added methionine. Nothing whatever could be observed in the corresponding position on the other paper.

It thus appears that methionine does not occur as such in normal urine. Presumably the titratable 'methionine' of Albanese *et al.*[1] is a conjugated form or derivative, the reducing properties of which correspond to those of methionine itself.

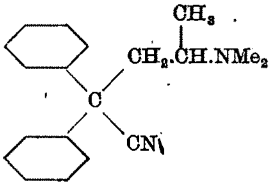
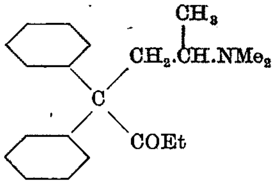
Optical Isomers of Amidone, with a Note on *iso*Amidone

l-AMIDONE has been briefly reported[1] to be an outstanding analgesic with about twice the activity of morphine, and this has recently been confirmed by us[2]. As no further chemical or pharmacological details appear to have been published, we give below a summary of our work in this field.

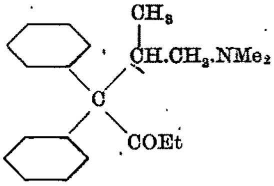
Attempts to resolve *dl*-amidone (II) using a number of optically active acids were unsuccessful. With *d*-tartaric acid it formed a diastereo compound, *dl*-amidone *d*-bitartrate, m.p. 128–133°, which crystallized unchanged from acetone and with alkali gave *dl*-amidone. The penultimate 1 : 1-diphenyl-3-dimethylaminovaleronitrile (I), on the other hand, was readily resolved by means of *d*-tartaric acid in wet acetone, from which the *l*-nitrile *d*-bitartrate (IV) crystallized in needles, m.p. 109–112°, $[\alpha]^{20}_D = +16°$ ($c = 1·44$ in water). The corresponding *d*-nitrile *d*-bitartrate (V), m.p. 66–70°, $[\alpha]^{20}_D = +5°$ ($c = 1·62$ in water), was obtained from the acetone mother-liquors by recrystallizing the crude product from wet acetone-ether. The *l*- and *d*-nitriles from (IV) and (V) were readily converted into *l*- and *d*-amidone respectively by means of ethyl magnesium bromide. Comparative data for these bases and their salts are given in Table 1. It will be seen that the salts of the optically active nitriles have anomalous rotations in water.



I



II



III

In view of the recently published work on the chemistry[3] and clinical trials[4] of *iso*amidone (III), it may be added that we have also prepared and examined this compound in the form of its nitrate.

The pharmacological properties of *d*- and *l*-amidone have been compared and are briefly reported in Table 2, together with some preliminary observations on *iso*amidone. These results are more accurate than our earlier observations[2], since the same methods were used with two dose-levels for each compound and a larger number of animals at each treatment.

The two experiments on analgesic activity referred to in the table were cross-over tests on rats arranged so that each rat had each treatment of drug and dose once over a period of several days. The first experiment was made on a total of eighty rats, and in the second forty rats were used. Morphine was used as the standard of comparison in each case.

It will be seen that the lævo-isomer is the pharmacologically active form. (Although an increase in pain threshold was observed after large doses of *d*-amidone, there was no well-established dose : response relationship, and hence this is not regarded as evidence of true analgesia. The reason for the toxic property of *d*-amidone is not yet known.)

The respiratory depressant activity was determined on 9–12 rabbits for each compound at two dose-

	1·5	—	16			

* See text note, p. 605.
† The two analgesic experiments are comparable with one another, since morphine was used as a standard of comparison in each case.

levels, but no effect was produced by *d*-amidone with doses comparable with those of the lævo-form. With a dose of 30 mgm./kgm. of *d*-amidone, approximately 30 per cent depression of respiration was seen.

Comparative experiments have been made with these compounds upon human volunteers, and the analgesic results in general resemble those given above for *d*-, *l*- and *dl*-amidone or morphine. The respiratory depressant action of *l*-amidone appears to be more than twice as great as that of *dl*-amidone, but *d*-amidone is almost without effect.

The toxic doses of the optical isomers of amidone upon intravenous injection in mice all lie between 15 and 18 mgm./kgm. for the L.D. 50 value, whereas the L.D. 50 for *iso*amidone nitrate is approximately 40 mgm./kgm.

In experiments upon the respiration of rat brain homogenate carried out by Dr. G. E. Glock, it was found that at concentrations of 0·005 *M*, *d*-, *l*- and *dl*-amidone produced similar degrees of inhibition of oxygen uptake of approximately 70 per cent. These results confirm those of Elliott[5] for amidone; but it should be pointed out that this concentration of drug is far greater than can be reached in the body after analgesic doses of these substances, and hence is of little practical significance.

Acquired Resistance (Twofold) to Quinine in *Plasmodium gallinaceum*

AFTER the introduction of the newer synthetic antimalarials, the possibility of acquired resistance of plasmodium strains to these drugs became important, analytically and clinically.

Experiments to examine this question were started in April 1946. Naturally the communications by Bishop and Birkett[1] and by Williamson, Bertram and Lourie[2] were very interesting to me. In my series of experiments I started with quinine; then I tried to produce resistance to 'Paludrine', and I can confirm the possibility of resistance. Among the strains in my laboratory there is one (*Plasmodium gallinaceum*) which by administering seven times 4 mgm./kgm. 'Paludrine' weekly had acquired after some fifteen weeks a high degree of resistance to 'Paludrine'. In contrast with Williamson, Bertram and Lourie, I was able to produce in *Plasmodium gallinaceum* a moderate, nevertheless clearly demonstrable, resistance to quinine. My method was as follows: on Monday, blood inoculation (50 million parasites) in a 7-day-old chick. Oral administration of a minimum active dose of quinine once on Monday, twice on Tuesday, Wednesday and Thursday, totalling seven doses. On Friday the results were checked. On the following Monday, blood inoculation of the drugged strain, as on the previous Monday, etc.

To produce 40–50 per cent reduction of the percentage of infected erythrocytes, as compared to untreated control animals, a dose of 10 mgm./kgm. quinine-base (administered as hydrochloride) was found to be necessary; 20 mgm./kgm. (also administered seven times) caused nearly total reduction. These results agree with those of P. B. Marshall[3].

Originally 10 mgm./kgm. quinine was administered; after 12 weeks this dose failed to cause reduction. After 16 weeks the dose was increased to 20 mgm./kgm. Against this dose, too, there arose gradually (after a further sixteen weekly treatments) a resistance, so that it caused no reduction at all (see Table 1).

TABLE 1

Normal strain		Q 37	
Controls (undrugged)	Quinine, 20 mgm./kgm.	Controls	Quinine, 20 mgm./kgm.
81% (4) infected erythrocytes	0·9% (5)	78·7% (5)	75·2% (5)

Q 37 stands for 37 treatments with quinine, of 7 doses each.
The number of birds in each experiment is given in brackets.

These results were repeated several times.

The quantitative estimation of this resistance was very important. Extensive experiments showed the resistance to be twofold: in the quinine-resistant strain, 40 mgm./kgm. quinine produced about the same action as 20 mgm./kgm. in a normal strain (see Table 2).

The increase of quinine resistance (twofold) is rather small as compared to 'Paludrine' resistance (40-fold);

TABLE 2

Normal strain			Q 51		
Controls	Quinine, 20 mgm./kgm.;	40 mgm./kgm.	Controls	Quinine, 20 mgm./kgm.;	40 mgm./kgm.
87% (12)	0·3% (10)	0·2% (9)	79% (10)	78% (10)	0·4% (10)
				Q 53	
		30 mgm./kgm.		20 mgm./kgm.;	30 mgm./kgm.
77 % (8)		0·1% (10)	63% (9)	56% (6)	18% (10)

experiments have been begun to ascertain if quinine resistance might be increased.

The essential difference between my experiments and those of Williamson, Bertram and Lourie is the fact that they used very large doses (150 mgm./kgm. daily in 516 out of 870 days) as compared to my doses of 20, later 40 mgm./kgm. daily, with three drugless days every week. How this difference bears on experiments with mepacrine, sulphadiazine and 3349 (I.C.I.) remains to be examined.

A further series of experiments served to examine if resistance is maintained after passage through the mosquito (*Aedes ægypti*) (see Table 3).

TABLE 3

Normal strain		Q 55 (through mosquito)	
Controls	Quinine, 20 mgm./kgm.	Controls	Quinine, 20 mgm./kgm.
87% (5)	0·2% (10)	43% (9)	8% (10)

Repetition of these experiments had the same results. So after one passage through the mosquito, acquired resistance to quinine is partially lost, in contrast with the persistence of acquired 'Paludrine' resistance. As regards quinine, this result agrees with those of Kritschewski and Halperin[4] (*Plasmodium relictum*), if one interprets their tables correctly.

The quinine-resistant strain appeared to be non-resistant to mepacrine, 'Paludrine' and chloroquine, because minimal active doses were as effective in the quinine-resistant strain as in a normal strain.

At present I am experimenting on the reaction of the secondary cinchona alkaloids and other anti-malarials. Also series of related experiments (inoculation of *EE* forms, loss of resistance, etc.) are in progress.

A detailed account of my results will be published later. I am indebted to the Imperial Chemical (Pharmaceuticals), Ltd., for the gift of 'Paludrine', and to the Nederlandsche Kininefabriek for the specially purified cinchona alkaloids. I am also grateful to Dr. F. Hawking (National Institute of Medical Research) for introducing me to the modern technique with *Plasmodium gallinaceum* and for putting a strain at my disposal; also to Dr. D. G. Davey, who demonstrated his laboratory technique. The experiments were carried out with the technical assistance of Miss Ella Pauw.

Freezing as an Aid in the Drying and Purification of Humus and Allied Materials

It is well known in colloid chemistry that the freezing of gels may cause coagulation, which is in some cases irreversible. We have found little evidence, however, that this phenomenon has been used to any great extent as a laboratory technique to simplify the bulk preparation of materials of a colloidal character.

In our work on soil organic matter, it is necessary to filter, reprecipitate and refilter frequently acid-precipitated flocculæ of humic acids (that is, materials allied to 'alkali-lignin' which constitute the bulk of soil organic matter). These materials, because of their large bulk, colloidal character and water-retaining capacity (greater than ten times their dry weight), are extremely difficult to filter and dry.

It has been found that, if the precipitates are frozen solid to a temperature of at least − 3° C. and then allowed to thaw, the colloidal properties are destroyed and the solid and aqueous phases separate. Moreover, the solid is in a condensed form, as irregular microscopic flakes, which are very readily filtered by standard methods.

The moisture content of a humus preparation has been reduced to one thirtieth of the original by a single freezing and thawing.

The colloidal character of the materials having been destroyed, they not only lose their water-holding capacity but also their general adsorptive power. Therefore, by washing with water, soluble contaminants are readily removed and a considerable degree of purification attained.

The presence of electrolytes is necessary for the freezing effect to take place, since in their absence the material reverts to its colloidal form on thawing.

The condensed humus can be regenerated in normal form by solution in alkali and precipitation with acid. The raw materials (soil, peat, or decomposed vegetable matter) are extracted with dilute (2 per cent) caustic soda and the alkaline extract acidified with sulphuric acid to a *p*H of approximately 3. The precipitated humus is allowed to settle, and after the supernatant liquor has been siphoned off, is frozen to − 3° C. It is then allowed to thaw, filtered, washed, and because of its small bulk and non-adsorptive powers is readily completely dried by standard methods.

The method is applicable to materials of similar properties such as 'alkali-lignin' precipitated from the waste liquors in the soda process, and may indeed have wide application in simplifying the preparation of plant structural substances in a readily handled form.

Effect of Oxygen on the Frequency of Chromosome Aberrations Produced by X-Rays

MOTTRAM[1] demonstrated that the effect of gamma- and X-radiations in inhibiting the growth of *Vicia faba* root tips was materially reduced if the exposure was made under anaerobic conditions, and that the change in radiosensitivity could not be correlated with a change in the proportion of cells in division at the time of irradiation. Crabtree and Cramer[2] had previously shown a similar effect of anaerobiosis on the radiosensitivity of tumour cells.

We have confirmed Mottram's result by irradiating with X-rays (H.V.L. 1 mm. Cu) groups of beans with their roots in a 'Perspex' cell of water through which nitrogen was bubbled. The cell was placed in a cardboard box with small holes for the egress of the nitrogen to minimize back diffusion of air. The nitrogen was bubbled for ten minutes, the radiation was given in the next ten minutes, and the bubbling of the nitrogen, which had continued during the irradiation, was kept on for five more minutes. The beans were then returned to the culture tank, where they were always in darkness to avoid a daily mitotic rhythm. Doses of 320 r., 255 r., and 175 r. were given to three groups, while three other groups were treated identically, but air was bubbled instead of nitrogen. In no case did the temperature of the water drop by more than 2° C. from the 19° C. of the culture tank. The growth curves of the nine beans in a group have been averaged and are plotted in Fig. 1, which illustrates the striking effect of the anaerobiosis on the radiosensitivity.

Experiments are in progress here to test Gray's[3] hypothesis that the lethal effect of ionizing radiations on the growing tip of the *Vicia faba* root is due to the genetic abnormalities which result from the division of cells containing aberrant chromosomes. The results so far have been in agreement with this view, and it was therefore believed that the decrease in radiosensitivity of the root tips in nitrogen should be accompanied by a parallel decrease in the proportion of cells having chromosome aberrations. Groups of beans have therefore been irradiated, as described above, except that the exposure time was reduced to 4 min. to match earlier experiments. The dose was 143 r. In the case of half the groups nitrogen was bubbled, and for the other half oxygen (not air). Again the temperature did not drop by more than 2° C. Tips were fixed at intervals up to 72 hours after the exposure; Fig. 2 shows the percentage of anaphases in which there were visible bridges or fragments. All but two of the points are based on 100 anaphases studied in each of two root tips. The yield of chromosome aberrations is also strikingly less when the irradiation is done in an atmosphere of nitrogen. As a similar reduction of radiosensitivity, as measured by growth subsequent to irradiation, was observed when nitrous oxide, carbon dioxide, and hydrogen were substituted for nitrogen, it seems clear that the availability of oxygen is a very important factor in the production of chromosome aberrations. It is possible that the effect of temperature observed by Sax and Enzmann[4], and Catcheside *et al.*[5], and the effect of pH observed by Marshak[6] may, at least in part, be due to differences in the availability of oxygen. That the radiosensitivity of tumours is affected by oxygen supply has long been suspected. It now seems likely that this influence does act through the effect on the production of chromosome aberrations.

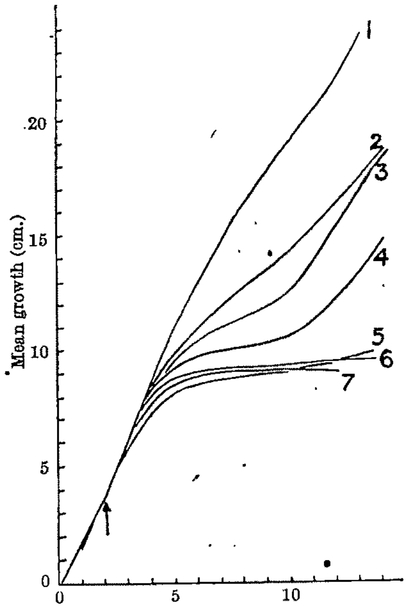

Fig. 1. EACH CURVE IS THE AVERAGE OF THE GROWTH CURVES OF A GROUP OF NINE ROOTS OF THE BROAD BEAN (*Vicia faba*) TREATED AS FOLLOWS ON THE SECOND DAY:

(1) 175 r. in nitrogen; (2) 255 r. in nitrogen; (3) 320 r. in nitrogen; (4) 175 r. in air; (5) 175 r. in oxygen; (6) 255 r. in air; (7) 320 r. in air

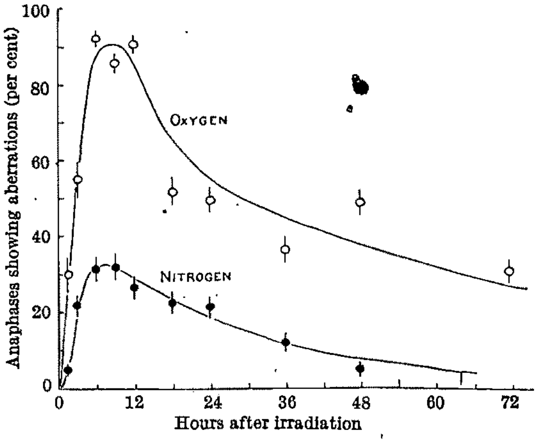

Fig. 2.

Upper curve—143 r. in oxygen; lower curve—143 r. in nitrogen

The details of these experiments and a full discussion will be published later. This preliminary report is given to direct the attention of those studying the production of chromosome aberrations by radiations to the importance of controlling the oxygen supply.

Initial Parenchyma Cells in Dicotyledonous Woods

STUDIES on living trees have shown that the concentric bands of parenchyma cells found in the diffuse-porous wood of *Terminalia tomentosa* W. and A.[1,2] are initial, that is, they are formed as the first tissues of a growth season. Some similarity between these parenchyma cells and those that occur in the early wood of ring-porous timbers was recognized, and in one specimen of *Terminalia tomentosa* W. and A.[2] a tendency to form semi-ring-porous structure was noticed, but nothing more than this was known at that time. Recently I have, however, come across some wood specimens of *Gmelina arborea* Roxb. which show not only both diffuse-porous and ring-porous structure but also some intermediate stages between these two extremes.

When *Gmelina arborea* Roxb. has a true diffuse-porous wood, the initial parenchyma cells may be altogether absent, although the growth rings may be visible due to the difference in the thickness of the fibre wall of early wood and that of the late wood of the previous year (Fig. *a*). In the first stage towards ring-porosity, the timber remains a diffuse-porous wood, but in between the early fibres and the late fibres of the previous year, a thin layer of initial parenchyma cells is usually present (Fig. *b*). This is exactly what was originally found in *Terminalia tomentosa* W. and A.[1]. At this stage, there may not be any appreciable difference between the size of the vessels within a growth ring, and the early vessel may not come in contact with the initial parenchyma cells. In the next stage, the timber has a semi-ring-porous structure. The somewhat large and scattered early vessels are partially embedded in the initial parenchyma cells. Finally, the timber shows a true ring-porous structure, where a clear row of large vessels are partially or wholly embedded in the initial parenchyma (Fig. *c*). Thus the part played by the initial parenchyma cells in the transformation of diffuse-porous wood to ring-porous wood is quite evident.

In tracing the development of initial parenchyma cells, it seems possible to detect some physiological cause for their formation. Forsaith[3] and Huber[4] have shown that rigour of growth condition is responsible for the formation of ring-porous timbers. It is therefore possible that *Gmelina arborea* Roxb. produces true diffuse-porous timbers when the growth conditions are mild, and semi-ring-porous to true ring-porous timbers when the conditions of growth are slightly to greatly severe. The capacity to vary its anatomical structure to suit the growth conditions would appear to be of a great help in maintaining its wide distribution.

Since the discovery of initial parenchyma cells in the wood of *Terminalia tomentosa* W. and A.[1], researches carried out at the Forest Research Institute, Dehra Dun, and elsewhere have shown that there are many diffuse-porous woods which have initial parenchyma cells; for example, *Dalbergia sissoo* Roxb.[5], *Swietenia macrophylla* King[6], *Salix matsudana* Koidz[7], and *Entandrophragma macrophyllum* A. Chev.[8]. On the other hand, some American workers[9] have questioned the validity of my original observations on *Terminalia tomentosa* W. and A. Based on some incomplete material collected from a few members of the Juglandaceæ, they were not able to decide whether to call these parenchyma cells terminal or initial. However, researches carried out in this laboratory have shown that the initial parenchyma cells are often a generic character and may in some cases be even a family character. Details of this investigation will be published elsewhere.

Willow as Host-Plant of *Crioceris merdigera*

A SHORT note by Mr. Saulnier in *Miscellanea Entomologica*, **43**, July 1947, p. 43, is headed "L'osier est-il une nouvelle plante hôte de *Crioceris merdigera* Linné ? (Chrysomelidæ, Coleoptera)". On two occasions he has found this chrysomelid beetle on osier-willow (*Salix viminalis* L. Salicaceæ), once on July 6, 1943, at La Booz, near Bretoncelles, Orne, and again on April 28, 1946, at Berdhuis, Orne. At first he thought it was accidental, but having found it a second time a note asking the above question seemed justifiable.

In order to understand the relationships between the insect and its host-plants, it is necessary to consider the group as a whole ; the host-plants of a single species of beetle constitute a datum which cannot by itself suggest relationships. According to the tables in my book (not yet published) the largest number of the Criocerinæ occurs on species of Gramineæ and Liliaceæ. Criocerine beetles have also been found on plants of families Commelinaceæ, Dioscoreaceæ, Orchidaceæ, Salicaceæ, Solanaceæ, Cucurbitaceæ, Compositæ and nine others.

There is one record of a criocerine beetle (*Lema lichenis* Voet = *Lema cyanella* Suffr. = *Crioceris cyanella* L.) attacking willows (see Fowler, "Coleoptera of the British Islands", p. 282 ; 1890). Mr. Saulnier's find is further evidence in support of the principle that when one species of a group of insects has been found to occur on a plant, others of the group may also be expected to occur on it.

Although the particular species which Mr. Saulnier has found on a willow has not been reported from that host before, the occurrence is thus not altogether unexpected.

Preparation and Properties of 3-Ethyl-5:5-dimethyloxazolidine-2:4-dione

It is stated by Spielman[1] that 3 : 5 : 5-trimethyloxazolidine-2 : 4-dione can be prepared by methylating 5 : 5-dimethyloxazolidine-2 : 4-dione in aqueous alkaline solution with dimethyl sulphate. Spielman failed to obtain the 3-ethyl analogue by this method using diethyl sulphate. A product, m.p. 61–62°, which was regarded as the 3-ethyl analogue, was, however, obtained by the action of ethyl iodide on the silver salt of 5 : 5-dimethyl-oxazolidine-2 : 4-dione.

It is now found that by treating the sodium salt of the dimethyloxazolidinedione in alcoholic solution with diethyl sulphate or with ethyl iodide, the 3-ethyl derivative is readily obtained. It melts at 76–77° and is not identical with the product obtained by the silver salt method. Thus the product, m.p. 76–77°, is stable to aqueous hydrochloric acid and with aqueous sodium hydroxide yields the sodium salt of N-ethyl-N-α-hydroxyisobutyrylcarbamic acid ; whereas the product, m.p. 61–62°, is unstable to hydrochloric acid, yielding the original 5 : 5-dimethyloxazolidine-2 : 4-dione and also to aqueous sodium hydroxide, yielding the sodium salt of the 5 : 5-dimethyloxazolidinedione.

The product m.p. 76–77° is regarded as being the true 3-(or N-)ethyl derivative, and that of m.p. 61–62° as an O-ethyl derivative of an enolic form of 5 : 5-dimethyloxazolidine-2 : 4-dione.

Further support for this view is found in the facts that the O-ethyl compound is readily converted to the N-ethyl compound by the action of heat and to the N-methyl, N-ethyl and N-*benzyl* derivatives when heated with methyl iodide, ethyl iodide and benzyl bromide, respectively.

Pharmacological tests carried out in these laboratories indicate that the 3-ethyl derivative is an anti-convulsant having an activity of the same order as that of the 3-methyl derivative.

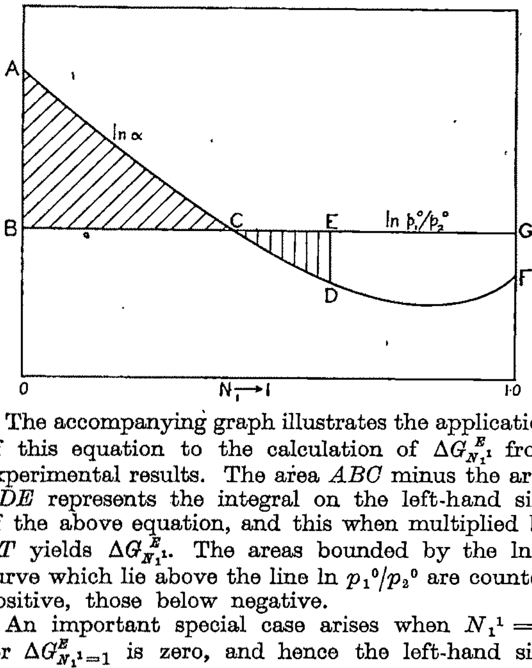
A Thermodynamic Test for the Internal Consistency of Experimental Data on Volatility Ratios

An important measurable parameter in the study of vapour-liquid equilibria in two-phase binary mixtures is the volatility ratio (α) defined by $N_1^g.N_2/N_1.N_2^g$, where N_1^g is the mol fraction of component 1 in the vapour and N_2^g that of component 2, while N_1 and N_2 are the corresponding quantities for the liquid. In view of the difficulties inherent in the determination of α, the need for a thermodynamic test of the reliability of experimental data has been expressed[1]. In this note such a test will be described and also a method given for deriving ΔG^E from the curve of α plotted against N_1, where ΔG^E is the excess free energy of formation of the mixture over an ideal mixture of the same composition. A study of this quantity (ΔG^E) is fundamental to the investigation of the structure of liquid mixtures.

The considerations will be restricted to the case where the vapours may be treated as ideal gases and where the molar volumes of the liquids may be neglected in comparison with that of the vapours. The expression can readily be modified to remove these restrictions, but when they are applicable it can be shown that equation (1) holds for isothermal conditions.

$$RT\int_0^{N_1^1}(\ln \alpha - \ln p_1^0/p_2^0)\,dN_1 = \Delta G^E_{N_1^1}, \qquad (1)$$

In this equation p_1^0 and p_2^0 are the vapour pressures of the pure components at T° absolute and $\Delta G^E_{N_1^1}$ is the excess free energy of formation of the mixture containing N_1^1 mols of component 1.



The accompanying graph illustrates the application of this equation to the calculation of $\Delta G^E_{N_1^1}$ from experimental results. The area *ABC* minus the area *CDE* represents the integral on the left-hand side of the above equation, and this when multiplied by *RT* yields $\Delta G^E_{N_1^1}$. The areas bounded by the ln α curve which lie above the line ln p_1^0/p_2^0 are counted positive, those below negative.

An important special case arises when $N_1^1 = 1$ for $\Delta G^E_{N_1^1=1}$ is zero, and hence the left-hand side of equation (1) is also zero, that is, the algebraic area bounded by $N_1 = 0$ and $N_1 = 1$ and the curves ln α and ln p_1^0/p_2^0 is zero when the above convention as to sign is employed. Thus, in order that the data shown in the graph should be thermodynamically consistent (subject to the above restrictions) it is necessary that area *ABC* should equal area *CDFGE*.

In practice, the ln α against N_1 curve has to be extrapolated to $N_1 = 0$ and $N_1 = 1$, which can usually be done with little error. The areas may be found either with the aid of a planimeter or by quadrature.

This test for the internal consistency of data refers strictly only to values found under isothermal conditions, but may be usefully applied in a semi-quantitative manner to isobaric data if the components are a close-boiling pair. Here the values of ln p_1^0/p_2^0 appropriate to the boiling point of the mixtures are plotted against N_1. The equation applicable to isobaric data when the components differ considerably in boiling point is rather more complex.

The derivation of equation (1) and examples of its use in the investigation of the systems thiophene – benzene and ethylene dichloride – benzene will be published elsewhere.

I am indebted to Dr. R. P. Linstead, director of the Chemical Research Laboratory, for permission to publish this note.

Hydrodynamics of Non-Newtonian Fluids

If the assumption is made that a fluid is incompressible, then the most general possible relations between the stress components ($t_{xx}, t_{yy}, \ldots$) and the strain-velocity components ($a, b, \ldots$) can be obtained as

$$t_{xx} = 2\Theta . a + 2\Psi . A' + p \ldots,$$
$$\text{and} \quad t_{yz} = \Theta . f + \Psi . F' \ldots \quad (1)$$

($a, \ldots f, \ldots$) are given, as in classical hydrodynamics, by

$$a = \partial u/\partial x \ldots \text{ and } f = \partial v/\partial z + \partial w/\partial y \ldots,$$

where (u,v,w) are the components of velocity at a point (x, y, z). ($A_1', \ldots F_1', \ldots$) are given, in terms of ($a, \ldots f, \ldots$), by the relations

$$A' = a^2 + \tfrac{1}{4}(g^2 + h^2) \ldots$$
$$\text{and} \quad F' = \tfrac{1}{2}gh + (b + c)f \ldots \quad (2)$$

p is a hydrostatic pressure. Θ and Ψ are arbitrary functions of the strain-velocity invariants K_2 and K_3, where

$$K_2 = ab + bc + ca - \tfrac{1}{4}f^2 - \tfrac{1}{4}g^2 - \tfrac{1}{4}h^2$$
$$\text{and } K_3 = abc + \tfrac{1}{4}fgh - \tfrac{1}{4}af^2 - \tfrac{1}{4}bg^2 - \tfrac{1}{4}ch^2.$$

The invariant $K_1 (= a + b + c)$ is zero, since the fluid is incompressible.

The stress *vs.* strain-velocity relations (1) are somewhat similar to those obtained by Reiner[1] for a compressible fluid.

For a Newtonian fluid, $\Psi = 0$ and Θ is a constant—the viscosity of the fluid. For a non-Newtonian fluid, Θ depends on the strain-velocity invariants K_2 and K_3. It appears, from (1), that for a general, incompressible fluid, there is a second physical parameter Ψ which must be specified in order to define completely the flow properties of the fluid. This, again, may be a constant, or may depend on the strain-velocity invariants K_2 and K_3.

Equations (1) have been applied to calculate the forces which must be exerted on the boundary surfaces of a general, incompressible fluid in the following two cases.

(i) A cylindrical mass of fluid is subjected to a single torsional motion, in which each point of the fluid moves in a circular path about the axis of the cylinder, in a plane at right-angles to it, its angular velocity ψz being proportional to its distance z from one end of the cylinder.

(ii) A mass of fluid is contained between two coaxial cylinders, which are rotated with respect to each other about their common axis, and each point of the fluid moves in a circular path about this axis, in a plane at right-angles to it, with an angular velocity Ω, which depends only on the distance from the axis.

In case (i), it is found that in order to produce the specified motion of the fluid, both azimuthal and normal surface tractions must be exerted on the plane ends of the cylinder. If Ψ is constant, then the normal surface traction Z which must be exerted at a point at a distance r from the cylinder axis is given by

$$Z = \tfrac{1}{4}\Psi\psi^2 (3r^2 - a^2), \quad (3)$$

where a is the radius of the cylindrical mass of fluid.

In case (ii), it is found that in order to produce the specified motion of the fluid, azimuthal surface tractions must be exerted on the cylindrical surfaces of the fluid, and normal surface tractions Z must be exerted on the plane-free surfaces. If Ψ is constant, the value of Z at a distance r from the common axis of the cylinders is given by

$$Z = -2\Psi(\Omega_1 - \Omega_2)^2 \left(\frac{a_1^2 a_2^2}{a_1^2 - a_2^2}\right)^2 \frac{1}{r^4}; \quad (4)$$

a_1 and a_2 are the radii of the inner and outer confining cylinders and Ω_1 and Ω_2 are their angular velocities.

In the calculations of both cases (i) and (ii) it is assumed that centrifugal and gravitational effects can be neglected. It is seen, from (3) and (4), that if $\Psi = 0$, $Z = 0$ for both systems. The effects which arise from the non-vanishing of Ψ are similar to those obtained by Weissenberg[2] with a variety of fluids. It does not appear, however, that his explanation of these effects can be a valid one, since it depends on the presence of an elastic component in the stress *vs.* strain relations for the fluid, which could not make itself evident in any experiment on steady-state flow. From the point of view of phenomenological theory, such effects can arise in a material which is not visco-elastic. Whether or not materials which show this effect are, in practice, visco-elastic is a matter which must be decided either on experimental grounds or by studying the dependence of Ψ and of rigidity on the constitution of the fluid.

This work was carried out as part of a programme of fundamental research undertaken by the board of the British Rubber Producers' Research Association, while I was a guest worker at the National Bureau of Standards, Washington, D.C. It is hoped to publish a fuller account elsewhere.

A Long-Term Plan for the Nile Basin

In an article on "The Nile Basin", vol. 7, in *Nature* of August 16, p. 215, Dr. C. E. P. Brooks directs attention to the fact that the theory underlying what we have called 'century storage' is not given in the book. This was omitted because it was thought better not to make a book dealing with Nile projects more difficult by including in it complicated theoretical investigations. It is the intention to publish a full account of these separately; but it may be opportune to give here a very short summary of what has been done, and also to clear up a point raised by Dr. Brooks as to the correctness of the formula: $R = 1{\cdot}65\,\sigma\sqrt{N}$, on which our scheme of projects depends. This relates to a set of N observations the frequency distribution of which is approximately Gaussian when no account is taken of their order, σ being the standard deviation and R the maximum accumulated excess or deficit of departures from the mean. In the case of a river discharge, R is the amount of storage required to meet accumulated deficits over a period N. The equation gives the mean value of R obtained from 71 sets of observations of river discharges, river levels, rainfall, temperature and pressure covering periods of from thirty to two hundred years, with two or three cases outside this range, and a mean period of 97 years.

The form of the equation was obtained by considering the case of tossing a set of coins N times when the result is equal numbers of heads and tails. The frequency distribution is approximately Gaussian for a set of ten or more coins. If there fall n heads and n tails, the number of orders in which this can occur is $2nCn$. Among these orders there are $2nCn+h$, in which at some point heads exceed tails by h or more (Whitworth, "Choice and Chance"). By giving h all values from 0 to n, a mean value for the maximum excess of heads over tails can be found. Using Stirling's approximation for $n\,!$ we find:

$$R = \sqrt{n\pi} = \sigma\sqrt{\tfrac{1}{2}N\pi} = 1{\cdot}25\,\sigma\sqrt{N}.$$

This is a first approximation and was verified practically by tossing 10 sixpences 1,000 times, with the following results:

N	Number of sets	Mean value of $R/\sigma\sqrt{N}$
100	10	1·11
500	2	1·26
1,000	1	1·19

It is to be noted that owing to approximations the above result does not hold for small values of N.

The investigation relates to sequences of chance events where there is no relation between one member and another. Meteorological elements, however, often show periods when, on the whole, values are high, and others when they are low. The tendency of this grouping is to give higher values for R than those found for purely chance distributions, and is the explanation of the difference between the mean values of 1·25 and 1·65 for $R/\sigma\sqrt{N}$ found for chance events and natural phenomena.

The variation of R with N for natural phenomena was examined, but the lack of records covering long periods made it impossible to distinguish practically between $R \propto N$ and $R \propto \sqrt{N}$, so the form arrived at for chance events was naturally adopted. Dr. Brooks agrees that the difference between the two formulæ is not serious from a practical point of view, and actually it is much less than he has calculated from the incomplete data on the diagram in the book.

Some discussions with Dr. W. Lawrence Balls had directed attention to a fundamental theoretical question arising out of the investigation; that is, what are the statistical properties of natural phenomena such as river discharges, rainfall, etc., having regard to their order of occurrence? Dr. Brooks' remarks lead also to this question. So far as the practical affair of water storage, which led to the investigation, is concerned, we have given a satisfactory solution which covers periods up to one or two centuries. It is this solution which has enabled us to draw up for the first time a detailed scheme of irrigation projects for the full development of Egypt and the Sudan. The scarcity of records covering several centuries and the mathematical difficulties have, however, so far prevented us from giving a complete theoretical solution, though work is continuing on this. Dr. Brooks has kindly supplied us with a series for 4,000 years of the thickness of annual mud deposits in Lake Saki, and the examination of these and of the Carnegie Institution data about tree rings may lead to interesting results. References to other long series of observations would be valuable to us.

The Missing Factor in Science

PROF. H. DINGLE, in his inaugural lecture at University College, London[1], has done me the honour of coupling my name with that of the late Sir Arthur Eddington as horrible examples of distinguished thinkers "making statements of the greatest import which even an intelligent child can see to be directly contradicted by the facts".

Unfortunately the statement ascribed to me that science is "the means of obtaining practical mastery over nature through understanding it" represents such a gross distortion of my expressed attitude towards the question that I cannot let it pass without protest. As any reader of my book[2] can see for himself, I have held that this view only represents one aspect of science which has to be taken account of in assessing the total significance of science. Though it is impossible to condense adequately the significance of such a complex activity as science in a few sentences, the following quotation from my final chapter does expose the superficiality of Prof. Dingle's judgment:

"We have seen science as an integral part both of the material and economic life of our times and of the ideas which guide and inspire it. Science puts into our hands the means of satisfying our material needs. It gives us also the ideas which will enable us to understand, to coordinate, and to satisfy our needs in the social sphere. Beyond this science has something as important though less definite to offer: a reasonable hope in the unexplored possibilities of the future, an inspiration which is slowly but surely becoming the dominant driving force of modern thought and action."

If I had said—which I have not—that science was *nothing but* "the means of obtaining practical mastery over nature", Prof. Dingle might justly reproach me with omitting many other weighty aspects. Curiously enough, this is not what he tries to do. Instead, he sets himself the impossible task of proving that science is not concerned with such mastery. It is therefore not surprising to find that of the four simple tests which he uses to disprove my alleged definition, the first and last are false, the second irrelevant and the third unscientific.

It is clearly not the acceptance criterion of scientific papers that can be expected to show the purpose of science, but their content and the aim revealed in each investigation. In the very copy of *Nature* in which this article appears there are nineteen communications of original research; of these no less than ten are directly concerned with the mastery of man over nature, as for example a letter on "Disease of Pyrethrum in Kenya", and all the remainder, with the possible exceptions of "Feeding Mechanisms of Water Bugs" and the "Individual Activities of Ants", are examples of "understanding of nature" only one remove from practical requirements. Lest this should be thought a reflexion on the purity of *Nature*, an examination of the last two numbers (1020 and 1021) of that most austere of scientific publications, the *Proceedings of the Royal Society* (A), shows an even greater proportion—11 : 8—of papers directly devoted to the mastery of nature. The criterion of acceptance of these papers is that they should be, as far as may be judged by competent men, significant and accurate, for these are necessary though not sufficient conditions for the effectiveness of action based on them.

Equally unreliable is Prof. Dingle's last criterion of the achievements of the recipients of prizes and medals. It is only necessary to look at the citations to see how often the value of the new knowledge to humanity is stressed.

As to Prof. Dingle's second criterion, the questions in the examination papers, it has nothing to do with the argument. However much we may deplore it, examinations to-day are designed to test competence and knowledge, not purpose.

It is the third criterion that is most surprising, particularly coming from Prof. Dingle, for it is neither more nor less than his old bugbear—the appeal to the authority; and not even to that of the fathers of the Church, of the founders of the Royal Society—but to the literary authors of the New English Dictionary. Neither they nor the authorities from which they collected their readings had any object beyond the fixing of commonly accepted meanings. When the compilation is done again, undoubtedly the new definition of science as "mastery over nature" will be cited, though I hope it will be attributed to Prof. Dingle and not to me.

Now it would not have been worth writing this letter if it was not for the fact that the very disagreement between Prof. Dingle and myself over definitions and proofs is the strongest argument for the need to provide for the undertaking of criticism of science which Prof. Dingle urges in the latter part of his address. I may find his arguments as feeble and wrongheaded as he finds mine childish and tragic, but we both agree that the question is important and that we must train, pay and honour those who devote themselves to an attempt to answer it.

We need a recognition of a science of science, of which the study of the history of science will provide the initial descriptive base, but which itself is pursued like other sciences by research and experiment. The motives, incentives, methods and organisation of science all need study by research teams. The sooner we realize that such investigation is as good science as any other, the sooner we shall cease to waste our time in muddle and controversy and get on with the job of science, whatever it may be found to be.

J. D. BERNAL

Birkbeck College
(University of London),
London, E.C.4.

---

[1] *Nature*, 160, 108 (July 26, 1947).

[2] "The Social Function of Science", by J. D. Bernal (Routledge, 1939).

I AM very glad indeed to know that Prof. Bernal supports my plea for criticism in science, and only slightly less so to learn that he disowns the view of science I ascribed to him. My article would have been worth writing for these results alone.

He implies, however, that I have distorted his previous writings; but re-reading confirms the first impression, which is not modified by the passage now quoted. Science is there described as an integral part of economic life and as offering a vague hope for the future, and this hope is presumably what he now emphasizes. But I was speaking of what science *is*, not of the many things it may be held to 'offer'. Unfortunately, lack of space demanded severe abridgment of my lecture, and I would ask those who feel that certain passages need qualification to read the full text just published by Messrs. H. K. Lewis and Co. It shows my awareness that science *can be used* for material ends, and Prof. Bernal's statement that I try to prove that science is "not concerned" with mastery over nature is, therefore, misleading. Our difference is perhaps best revealed by his statement that the criterion of acceptance of papers is significance and accuracy, "for these are necessary . . . conditions for the effectiveness of action based on them". I hold that the criterion is "significance and accuracy" irrespective of whether action can be based on them or not.

I cannot accept Prof. Bernal's criticism of my tests for the nature of science. I still maintain that the "acceptance criterion" and not "content and aim revealed" (in so far as these are separable from the acceptance criterion) is the proper clue to the meaning of science; indeed, it seems to me obvious. *Nature* is not the kind of journal I mentioned. I do not agree with Prof. Bernal's analysis of the last two numbers of the *Proceedings of the Royal Society* (A), but I am astonished that, after declaring that "the history of science will provide the initial descriptive base" of the study of science, he should base his own arguments on the last two numbers of the *Proceedings of the Royal Society*, and the next edition of the New English Dictionary. I did not expect to find him so "deceived by the momentary appearance of a movement which after taking 2,000 years to prepare itself, has been gathering momentum for the last 300 years". It would surely not be surprising if, after several years in which all scientific effort was perverted to a particular end and kept secret, the early succeeding papers should show an abnormal possibility of practical application, though I maintain again that that would not be why they would be accepted for publication and, therefore, would not be the clue to the 'science' in them.

Finally, I am puzzled to know why Prof. Bernal, while acknowledging that the New English Dictionary merely gives "commonly accepted meanings", should charge me with "appealing to authority" by referring to it. I turned to it for "commonly accepted meanings", assuming that, if Prof. Bernal's book was to be trusted, the "mastery over nature" view should be there. His book states (p. 6) that that view (now described as "new" and attributable to me) was present in classical times, appears explicitly in Roger Bacon and at the Renaissance, and is fully expressed in its "modern" form by Francis Bacon. "This," he adds, "remained the predominant view of science for at least two hundred years." Why is it not mentioned in the Dictionary, and why will it "undoubtedly" appear next time ?

VALVE WITH TROCHOIDAL ELECTRONIC MOTION

By Prof. H. ALFVÉN and H. ROMANUS

Kungl. Tekniska Högskolan, Stockholm

IN a homogeneous magnetic field an electron with a velocity perpendicular to the field moves in a circle. If an electric field is applied perpendicularly to the magnetic field, the circle 'drifts' with a velocity which to a first approximation (electric field not too strong) is

$$\mathbf{v} = -\frac{c}{H^2}\mathbf{H} \times \mathbf{E}.$$

The combined motion is a cycloid or trochoid. As the drift is perpendicular to the electric field, the circle in which the electron moves is displaced along *an equipotential line.*

If a beam of electrons moving in cycloids or trochoids is produced, this beam follows that equipotential line on which it started. As in a valve an equipotential line is easily changed and can be given almost any desired shape, a trochoidal beam possesses a high flexibility and can be used for many technical purposes, for example, the construction of electronic switches and counters.

During recent years research on valves with cycloidal or trochoidal electronic motion has been carried out at this laboratory. The development of the valves, which are called 'trochotrons', has been carried out by G. Hambraeus and, especially, T. Wallmark. Different circuits for the valves have been worked out by Lindberg, Lundquist, Warring and Åström.

The type of valve mostly used at present is shown diagrammatically in Fig. 1.

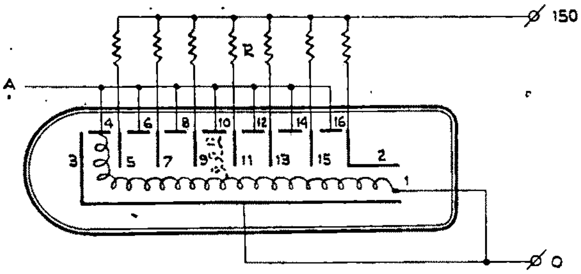

Fig. 1

A homogeneous magnetic field (100–200 gauss) is applied perpendicular to the plane of the paper. The filament 1 emits electrons which are attracted by the anode 2. Due to the magnetic field, however, they never reach the anode. Instead, a trochoidal beam is formed travelling along an equipotential line of the electric field formed between the electrode 3, which is held at zero or negative potential, and the electrodes 4–15, normally given positive potentials of 100–200 volts. The whole current emitted (about 1 mA.) is thereby received by the 'plate' 4.

If the potential of one of the electrodes 5, 7, 9, 11, or 13 (the 'guides'), for example, that of 9 is decreased to about 20 volts or lower, the equipotential line followed by the beam enters the box between 9 and 11. The current goes to plate 10, and in part also to guide 9. If this is connected to the voltage supply through a resistance R, the voltage drop in R will maintain the low potential on the guide. Consequently, if once *the beam is brought into a certain box it remains locked up there.* In other words, the electron beam of the valve has the peculiar quality that it is attracted to an electrode having a certain voltage, but diverted from the same when the voltage is decreased or *increased.* This implies a negative slope in one part of the voltage-current characteristic of all the electrodes in the valve, that is, every electrode may under certain voltage conditions act as a negative resistance. The characteristic of an electrode is shown in Fig. 2, where AB represents a series resistance, giving the locking position C.

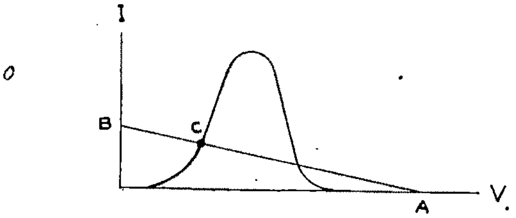

Fig. 2

The great flexibility of the trochoidal electron beam also makes it possible to use 'two-dimensional' electrode systems as in Fig. 3. If all electrodes except 0 are held at a high positive potential, the current goes to the plate 00. It may be switched, for example, to the plate 21 by putting the vertical guide 2 and the set of horizontal guides 1′ under zero voltage.

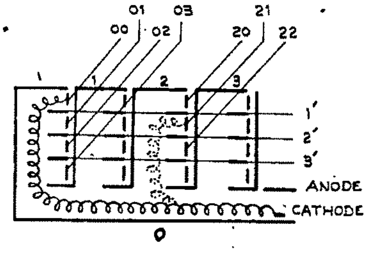

Fig. 3

A 10-box valve (see Fig. 1) is preferably used as an electrical counter ('scale-of-ten'). The pulses to be counted should be negative. They are applied to A, which is normally held at about 100 volts. Suppose that the beam at the beginning is landing on plate 4 in the first box. A decrease of the potential of this plate will displace the beam towards guide 5. Due to the resistance R in series with this electrode, the potential of 5 will immediately drop, so that the beam is brought into the second box. The next pulse will displace the beam from plate 6 to guide 7, which through a potential drop transfers the beam to the third box and so on. Finally, on arriving at guide 15, the beam is transferred to anode 2, and the anode potential will drop in the same way due to a series resistance, with the result that the emission from the cathode is cut off for a moment. Hence the initial conditions are restored so that the beam again goes to plate 4. Thus the valve may be operated as a cyclic switch. From the anode or one of the guides, every tenth of the input pulses may be tapped to another scale-of-ten unit or to a mechanical counter. Neon lamps in series with the plates may be used to indicate the actual position of the beam.

In this way the trochotron is used in electric counters and chronoscopes. It seems also to be a useful unit in calculating machines. A system for pulse-time modulated multiplex telephony has also been worked out, in which the valve is used as a cyclic switch and modulator or demodulator simultaneously.

Detailed reports of the investigations are in preparation.

INDEXING PRACTICE: TRENDS IN GERMAN, AMERICAN AND BRITISH CHEMICAL SOCIETIES' PRACTICE

By R. BRIGHTMAN

Imperial Chemical Industries, Ltd., Manchester

MOST organic chemists have found in literature searches that the tracing of entries relating to particular compounds may be difficult because of inconsistencies in indexing practice. For example, although in the introduction to the Collective Index 1923–32 to *British Chemical Abstracts* there is given a list of substituents such as amino-, chloro-, nitro-, etc., which in the Index are placed immediately after the remainder of the name, whether or not the substituent group is preceded by di-, tri-, etc., and although the name of the individual compound commences with that substituent, previous practice had varied. In earlier volumes "Nitrotoluene", for example, may be found under "Toluene, nitro-", "Nitrotoluene" or "Paranitrotoluene", with or without appropriate cross-references. Again, in one volume, "Nitrochloronaphthalene" appears as well as "Naphthalene-, nitrochloro", but "Tetranitronaphthol, α-", is given only under "T", whereas "Trichloroacetic acid" appears under "Acetic acid, trichlor-". Disregarding variations in spelling, "paranitroaniline" is indexed under "P" (Paranitroaniline), under "A" (Aniline, p-nitro-) and under "N" (Nitroaniline, p-), and the nitrotoluidines under "Aminotoluene, nitro", under "Nitro-toluidines", under "Toluene, nitroamino" and under "Toluidines, -nitro".

It is not surprising that consistency in indexing should grow slowly; and the present time may even be one of maximum confusion, due to the continual increase of potential morasses through the expansion of technical chemistry, as a comparison of college text-books of organic chemistry of the last thirty to forty years will illustrate. None the less, the present inconsistencies imply that, to be sure of finding all references to a chemical compound from the Indexes to the abstracts issued by the Chemical Society or the Society of Chemical Industry, one would require to scan the Indexes not only under the name of the present compound but also under all the possible variations in arrangement of parts of the name, and this without systematic guidance from the Index itself.

Such circumstances have induced a preliminary study of indexing practice of *British Chemical Abstracts*, the *Chemische Zentralblatt*, and *Chemical Abstracts*. In this study, the results of which are here presented, the comprehensiveness with which the literature is covered, questions of cost or other points of economics, interval between the appearance of the original paper and the abstract, and the qualifications of indexing staff, have not been considered. The prime purpose has been a comparison of the three systems in practice in regard to the indexing of chemical compounds, and, as a sample, the indexing of some typical compounds, namely, butadiene, the butylene glycols and ethylene glycol over the last fifty years was examined.

Ethylene Glycol

Chemische Zentralblatt. In the Index to the 1897 volume this compound is entered under "Glykol". "Äthylen Glykol" appears in the Collective Index for 1897–1901, but there is no cross-reference to or from "Glykol". A similar remark applies to the 1899 Index. In the 1900 Index, "Glykol" is used as a generic term. Separate entries appear under both names in the 1901 Index, while from 1905 onwards entries under "Glykol" are differentiated by formulæ. In 1906 and subsequent Indexes there is a cross-reference from "Glykol" to "Äthylen Glykol", but the Collective Indexes 1897–1921 contain entries under "Äthylenglykol" with a cross-reference "Glykol see Äthylenglykol". In the 1922–24 Collective Index this practice is reversed. Entries are placed under "Glykol (Äthylenglykol)" with an entry "Äthylenglykol—See Glykol", and in the 1925–29 Index the entries under "Glykol" are classified in the usual manner under "preparation, physical properties, chemical properties". Thereafter entries are consistently placed under "Glykol" with cross-reference "Äthylenglykol—See Glykol".

British Chemical Abstracts. The Indexes to the Chemical Society's *Abstracts* for 1897 and 1898 contain the entry "Ethylenic Glycol", and in 1899 there is the cross-reference "Glycol, see Ethylenic Glycol". During 1900–13 this becomes "Glycol. See Ethylene Glycol", and entries are placed under "Ethylene glycol". The latter term is the sole entry in the Indexes for 1915–17 and 1920–26, but in 1918 and 1919 the cross-reference "Glycol. See Ethylene glycol" is again given, and also in the Collective Indexes, 1903–12, 1913–22, 1923–32 and 1933–37 and the Annual Indexes to *British Chemical Abstracts* from 1927 onwards, with the exception of those for the years 1934–36 and 1943–44, when the cross-reference from "Glycol" is dropped although the entries are still placed under "Ethylene glycol".

Chemical Abstracts. In the Indexes to the 1907–9 volumes there are entries under "Ethylene glycol" and "Glycol" with no cross-reference. In 1910 there are entries under "1 : 2-Glycol" but none under "Ethylene glycol". In 1911 "Glycol" only is entered, and in the following year both "Ethylene glycol" and "Glycol" appear without cross-reference: the entries under "Glycol" in this year (1912) relate to derivatives. Entries in 1913 and 1914 are similar, but in 1915 under "Glycol" there is entered "See also Ethylene Glycol". In 1918 under "Glycol" is entered the note: "Individual glycols not having a common name, e.g., glycol, are indexed under the Geneva name, e.g., Propanediol". This note is repeated in 1919 and afterwards. The same volumes contain the entry "Ethylene glycol. See Glycol. For derivatives see 1 : 2-Ethanediol, 1 : 2-Propanediol, etc.", and this is repeated at intervals down to 1944.

Butylene Glycol

The indexing of butylene glycol in the period 1901–44 presents a similar picture. In the *Chemische Zentralblatt*, entries are made both under "Butylen glykol" and "Butandiol", and only in 1919 is there a cross-reference "See Butylen glykol" under "Butandiol". But from 1922 onwards entries under

"Butandiols" and "Butylen glykols" are transferred to the Formula Index.

In *British Chemical Abstracts* and *Chemical Abstracts*, entries are made both under "Butylene glycol" and "Butane diol", frequently without cross-reference; and although the tendency in *Chemical Abstracts* from 1918 onwards is to enter under "Butane diol" in accordance with the note already quoted under "Ethylene glycol"—"Individual glycols not having a common name, e.g., glycol, are indexed under the Geneva name, e.g., Propanediol"—the Index to the volume for 1920 contains the entry "Butane diol. See Butylene glycol".

Butadiene

Chemische Zentralblatt. "Butadiene" first appears under that name in the 1897–1901 Collective Index. The Index to the volume for 1903 contains an entry under "Erythren" but nothing under "Butadiene". In the 1902–6 Collective Index all three names, "Butadiene", "Erythren" and "Divinyl", are entered, but there are no cross-references. There is a reference under "Erythren. See Divinyl" in the 1911 Index, but "Butadiene" is entered separately with no cross-reference. In the index to the second volume for the same year, "Butadiene" and "Erythren" are entered separately with no cross-reference or to "Divinyl". In 1912 there is an entry under "Erythren" and a cross-reference "Butadiene. See Erythren". In 1913 "Divinyl" and "Erythren" are entered separately for the first half-year, and in the second half-year there are entries "Butadiene" and "Erythren" but with no entry for "Divinyl". The Indexes for 1914 and 1915 contain entries for "Butadiene" and "Erythren" but no cross-reference; and in 1916 there are entries under "Divinyl" and "Erythren" but not under "Butadiene", and there are no cross-references. Similarly, the entries in 1918 under "Divinyl" and "Butadiene" are without cross-references; and also in 1919 under "Butadiene" and "Erythren" and in 1921 under "Butadiene". The 1912–15 Collective Index refers from "Butadiene" to "Erythren" and *vice versa*, but there is no reference from either to "Divinyl", which is entered without a cross-reference. In the 1917–21 Collective Index, "Divinyl" and "Erythren" are both entered without cross-reference and there is no entry under "Butadiene". In the following Collective Index (1922–24) there are entries "Erythren. See C_4H_6", "Butadiene. See C_4H_6", but there is no entry under "Divinyl". In the next Collective Index (1925–29) all three names are referred to the Formula Index.

British Chemical Abstracts. Much the same variations are found in the *Abstracts* of the Chemical Society and in *British Chemical Abstracts*. In 1899 the entry "Divinyl. See Butinene" occurs, while "Butinene (Divinyl)" is also entered. In 1901 the following entries are made:

> "Butinene (Ethylacetylene),
> Butinene (Crotonylene, dimethylacetylene)";

but there is none under "Butadiene", "Divinyl" or "Erythrene". "Butadiene" appears in 1904, and in 1905 in addition to "Butadiene" and "Erythrene" there is the entry "Butinene. See Erythrene". "Butadiene" alone is entered in 1906, "$\Delta^{\alpha\gamma}$-Butadiene" in 1907, "n-Butinene" in 1909, and "Butadiene" and "Erythrene" in 1912. In 1913 there are the following entries: "Erythrene", "$\Delta^{\alpha\gamma}$-Butadiene", "Δ^{α}-Butinene", "Δ^{β}-Butinene. See Crotonylene". In 1914 there are entries for "Butadienes", "$\Delta^{\alpha\gamma}$-Butadiene", "Δ^{α}-Butinene" and "Erythrene" but no cross-references; in 1915 "Butadiene"; in 1916 "Divinyl" and "Erythrene" (without cross-reference); in 1917 "Divinyl"; and in 1923 "Butadienes" only. In 1924 "Butadiene", and "Δ^{γ}-Butinene $CH_2 : CH.CH : CH_2$" are entered, while the Collective Index 1923–32 gives "Butadiene", "$\Delta^{\alpha\beta}$-Butadiene", "$\Delta^{\alpha\gamma}$-Butadiene", "Butadienes", "Erythrene (See also Hydrocarbons, erythrene)", "Divinyl"; but without other cross-references. The Collective Indexes, 1903–12 and 1913–22, similarly give all three terms without cross-references. Similar inconsistencies persist in the annual indexes down to 1940. Some years one term is used and in others another, with no cross-reference in either volume. For example, in 1926, both "Butadiene" and "Erythrene" appear; in 1930 "Butadiene" and "Divinyl"; while in 1934 all three are entered. "Divinyl" appears again in 1937 and 1938, but not afterwards. "Erythrene" is only entered again in 1939 and thereafter entries are under "Butadiene" or "$\Delta^{\alpha\gamma}$-Butadiene", but without cross-references.

Chemical Abstracts. "Butadiene" first appears in the Index to *Chemical Abstracts* in 1911, and in 1912 "Butadiene", "Divinyl" and "Erythrene" are all entered. In 1913 "Butadiene" and "Erythrene" are entered; all three appear in 1914 and 1915; but not until 1916 are there cross-references, when "Divinyl" is made the main entry and "Erythrene" and "Butadiene" are entered with the note "See Divinyl".

This practice, however, was not adhered to rigorously, for in 1918 there are entries under "Butadiene" but not under "Erythrene" or "Divinyl", and the entry "Bivinyl" and the cross-reference "Butadiene. See Bivinyl" do not appear until 1921. In 1922 "Butadiene" and "Divinyl" are entered, but not "Bivinyl" or "Erythrene". In 1923 "Butadiene. See Bivinyl" is again entered, but the only entry under "Erythrene" is "Erythrene, αα-dimethyl—See 1 : 3-Pentadiene, 4-methyl-". In 1925 there is the entry: "Bivinyl (erythrene) (for derivatives, see under 1 : 3-butadiene, etc.)" and also "Erythrene, see Bivinyl", both of which are repeated in 1926. The entry "Divinyl, see Bivinyl" is not repeated in 1926, although this volume includes the entry "1 : 3-Butadiene, see Bivinyl".

The indexing appears to become more systematic from 1927 onwards, though the editors appear to be unable to make up their minds which name to adopt as the main entry. Thus in 1927 we find "1 : 3, Butadiene, see Bivinyl"; "Erythrene, see Bivinyl"; "Bivinyl (Erythrene). For derivatives see under 1 : 3-Butadiene, etc.", and in 1928 "Divinyl, see Bivinyl". In 1931, however, there are no entries under "Divinyl" and "Erythrene", and under "Bivinyl" is entered "see 1 : 3-Butadiene". There are no cross-references from "Butadiene". Again, although in 1934 and 1935 "Bivinyl" is entered "see Butadiene", and "Butadiene (bivinyl)", there are no entries or cross-references for "Divinyl" and "Erythrene". In 1937 there is entered "Bivinyl (Erythrene), see also Butadiene"; "1 : 3-Butadiene, see also Bivinyl"; "Divinyl, see Bivinyl"; "Erythrene, see Bivinyl". In 1938 "Bivinyl" is entered "see 1 : 3-Butadiene"; but although bivinyl is given in brackets after "Butadiene", there are no entries under erythrene or divinyl. In 1941 "Butadiene" is entered "See also Di- under Olefins" and "Olefins, di-", "See also Rubber substitute and synthetic". In 1942–44 butadiene is entered "Butadiene (Bivinyl).

See also "Rubber substitute and synthetic" and in "Di-" under "Olefins".

These examples indicate that while cross-referencing in the indexes to *Chemical Abstracts* is no more systematic than in *British Chemical Abstracts*, it is somewhat more complete. What is more impressive, however, when the indexes are compared, is the extent to which the editors of *Chemical Abstracts* have from the start attempted to define precisely the indexing policy followed and to modify this from time to time to incorporate any practice on which some general international agreement has been reached. For example, in 1938–40 the nomenclature and indexing for inorganic compounds was modified in accordance with the recommendations of the report of the German Commission (*Helv. Chim. Acta*, **20**, 159; 1937) and the rules of the Commission on the Reform of the Nomenclature of Inorganic Compounds (*Ber.*, **73A**, 53; 1940; *J. Chem. Soc.*, 1404; 1940); while in 1935 Crane's modified Broughton system was brought into use for deuterium compounds (*Ind. Eng. Chem., News Ed.*, **13**, 200; 1935). In the 1938 Index the practice used in botanical and zoological nomenclature is also defined, and the authorities used for insects, for bacteria, and for alloys are specified.

The practice followed in indexing organic compounds is described in detail in prefaces to the indexes to successive volumes, notably in those for 1917, 1927, 1937 and 1945, and the Collective Indexes for 1907–16 and 1917–26. The basis of this has been the system of organic chemical nomenclature described by A. M. Patterson and C. E. Curran (*J. Amer. Chem. Soc.*, **19**, 1623; 1917), and the most striking change in the indexing methods is the inversion of all names containing substituent prefixes, "Chloroacetic acid", for example, being now placed under "Acetic acid, chloro-". This is in keeping with the principle laid down in the preface to the 1918 volume that subjects, not words, are indexed; but the idea of arranging alphabetically on the basis of the parent compound was taken from the *Journal of the Chemical Society*, although it was not until the 1923–32 Collective Index that the practice was systematically adopted in *British Chemical Abstracts*. Afterwards, in 1937, some changes were made towards the adoption of the Rules given in the Definitive Report of the International Committee on Organic Nomenclature (*J. Chem. Soc.*, 1607; 1931; *J. Amer. Chem. Soc.*, **55**, 3905; 1933; cf. also C. Smith, *J. Chem. Soc.*, 1067; 1936). Although there is nothing to indicate the fact in prefaces to *Chemical Abstracts* or *British Chemical Abstracts*, according to a paper by E. J. Crane (*J. Chem. Educ.*, **8**, 1335; 1931) in 1923 the Nomenclature Committee of the Chemical Society, London, and that of the American Chemical Society, agreed on the rules covering some of the more commonly disputed points, including some of significance for classification.

In contrast to this it is difficult to trace definite evidence that any of these reports on organic or inorganic nomenclature or on the nomenclature of deuterium compounds have been adopted in British practice. Apart from a brief preface to the Collective Indexes for 1883 and 1892, according to which the index is in the main alphabetical, but wherever practicable substances are arranged alphabetically and under such well-defined main groups as alkaloids, carbohydrates, glucosides, etc., there is no further preface or explanatory note until the Collective Index for 1923–32, when the practice already noted of placing certain substituent groups after the remainder of the name is adopted. Some indication as to indexing practice may be found in the "Instructions to Abstractors" which are sometimes to be found bound with the *Abstracts*, although I have not been able to trace an issue earlier than 1918. Much of this, and indeed the use as standard of reference of the Collective Indexes of the Chemical Society, 1913–22 and 1923–32, involves the translation of names used in American and other chemical periodicals, to fit rather a set of rules than a defined system or set of principles.

From this preliminary survey certain tentative conclusions can be drawn.

(1) *Chemical Abstracts* represents the most persistent attempt to provide adequate alphabetical indexing of chemical compounds by name; but even in current practice, room for considerable improvement can be seen.

(2) Both in *Chemical Abstracts* and in *Chemische Zentralblatt* there can be seen a distinct trend towards a formula index for indexing definite organic chemical compounds, in view of variations in chemical nomenclature and to allow for compounds not named by their originators.

(3) There is some evidence of a trend towards agreement on nomenclature between the British and American Chemical Societies, but progress in this direction is unlikely to be rapid and the general adoption of an international system by all chemists is a remote probability, even disregarding the fundamental difference of mother tongues.

(4) Independently of the question of coverage and of the economic aspects of abstracting, on the basis of circulation and resources, it is now improbable that *British Chemical Abstracts* could ever hope to compete with *Chemical Abstracts*; nor has this survey revealed any reason for making the attempt.

(5) The law of scattering deduced by the late Mr. E. Lancaster-Jones in an investigation instigated by Dr. S. C. Bradford (cf. *Engineering*, **137**, 85; 1934; also *Rep. Proc. 14th Conf. Assoc. Spec. Lib. and Inform. Bur.*, 1937, pp. 59–71; and *F.I.D. Comm.*, **13**, 61–65; 1946) suggests that the best means of securing complete cover is not by rival abstracting organisations, but by functional co-operation and laying out the field by sciences on some such basis as the Universal Decimal Classification.

The most important development to be desired appears to be the standardization of indexing practice, probably on the basis of formulæ rather than names, and the establishment of some central body with adequate resources to provide comprehensive annual and decennial, or other periodic indexes, as may be most convenient, for English-speaking chemists. Since reports from Germany (cf. *Ind. Eng. Chem., News Ed.*, **24**, 790; 1946) suggest that the future of the *Chemische Zentralblatt* is highly uncertain, this appears to be the most urgent need and much more essential than the question of abstracting. If any financial resources can be set free for the purpose by elimination of redundant abstracting, that might strengthen the case for Government assistance if required. Since, however, the provision of such comprehensive indexes would be of great assistance to industrial research in particular, it should not be difficult to make out a strong case in the first instance for support by industry as well as by the State.

ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION

THE ninety-second annual exhibition of the Royal Photographic Society has this year, for the first time, been held in two sections on view at different times. It will be recalled that last year the whole exhibition was displayed in a gallery at the Science Museum, London, at the same time as the special exhibition commemorating the centenary of photography. This year the exhibition has returned to the Society's House at 16 Prince's Gate, London, S.W.7, and the experiment has been tried of division in time to permit both sections more space. Part 1, which was pictorial in outlook, was shown first, and was followed by Part 2, which had a scientific outlook. The lantern slides, colour transparencies and stereoscopic exhibits, most of which belonged to Part 1, were shown for the whole period of the exhibition.

The scientific section was as usual dominated by the natural history exhibits, which are well up to standard in quality as well as quantity. By far the majority of exhibits are photographs of birds in their natural surroundings, and we can but admire the ingenuity and patience that enables the photographer to approach such timid creatures sufficiently closely to produce such fine photographs. Two exhibitors received the Society's Medal for their entry. High-speed flash photography has been used to produce some remarkably interesting records of birds in flight. A redstart is photographed in various attitudes when approaching to alight on a twig and illustrates well the use of the wings as a brake. Perhaps the most remarkable high-speed photograph is that of a tawny owl flying towards the camera with a mouse in its beak. The movement has been arrested and the bird is in perfect focus, though it can be seen from the ground that the depth of field is relatively small. One wonders whether this was secured by perfect timing or whether some tripping device was used. Of all the exhibits, which in addition to birds included insects and flowers, it may be said that most of them, as well as providing a record, have artistic merit of their own and can be enjoyed by the physicist and chemist as well as by the ornithologist and botanist.

The next largest entry was in the so-called Record Press and Commercial Section. This always seems a little out of place among the scientific and technical exhibits, consisting, as it invariably does, mainly of photographs of carvings in churches, abbeys and other ancient buildings. However, recent experience during the years of destruction should have taught us the great value of records of the kind shown, and if such recording could be placed on a firmer scientific foundation, the results would be of even greater value.

The Scientific Section was quite well represented, but one cannot help comparing it unfavourably with the display at the Science Museum last year. There were forty-four exhibits, mainly photomicrographs. Of special merit was the exhibit awarded the Rodman Medal, illustrating in a series of six photomicrographs the development of the brittle starfish (*Ophiothrix fragilis*). The following is an extract from the catalogue: "It is believed that this is the first time that the development of a brittle-star has been illustrated by photography of the living larvæ. The various stages were obtained from the plankton, transferred to filtered sea water and photographed, without narcotization, under dark-ground illumination, a variety of objectives and eyepieces being used. Exposures were generally about one-fifth of a second."

There was an interesting series of photographs of triangular markings on the natural surface of a diamond crystal. These markings are often deep with steep sides, and the series consists of photomicrographs illustrating the patterns produced with the crystal surface in contact with an optical flat. The depth and contour of the sides of the hollow can be better interpreted by the use of unfiltered mercury light than by monochromatic light. The high-speed exhibit, which has for years introduced something new and interesting, was disappointing, though it contained one of the most remarkable pictures in the whole exhibition. It is entitled "Milk Bar" and was photographed during a milking operation when a fine jet of milk was directed horizontally. This jet of milk was incident normally on the end of a cat's nose, the cat having reared up on its haunches in order to reach the stream. The expression on the cat's face defies description. This photograph was submitted in this section on the somewhat ingenuous excuse that it illustrates the fact that the jet of milk is divided into droplets. Whatever we may say on the subject of suitability of subject-matter, no human selection committee could possibly have rejected this photograph.

Finally, in order of number of exhibits, came the Medical Section. This contained sixteen exhibits including the 'before and after' type illustrating the results of plastic surgery, photographs of surgical specimens, and clinical photographs.

STANDARDIZATION IN INDUSTRY

"THE History and Philosophy of Standardization" might serve as a descriptive title for the main theme of the presidential address of Mr. Percy Good delivered before the Institution of Electrical Engineers on October 9.

From the simple beginnings with weight, length and volume standards already recognized in antiquity as necessary concomitants of trade in and between civilized communities we have erected, in modern times, a vast and complex structure of standards and codes of practice to meet our present-day needs. "Just as it became necessary", said Mr. Good, "from the earliest trading days to have standards for comparing or measuring quantity so, to-day, when in a very large number of cases weight, area or volume have no significance in determining the suitability or value of a product, standards are required to enable the properties which are significant to be assessed in comparable terms." The industrial standards employed to-day comprise the following classes: standards of quality, fitness for purpose or performance; dimensional standards; standard methods of sampling, and certification marking; terms, definitions and symbols (nomenclature).

Referring to dimensional standards, which have as a primary purpose the securing of interchangeability and the establishing of a range of types, experience during the War provided instances in which requirements could be met by types numbering perhaps dozens where hundreds or even thousands of types had previously been manufactured. Each industry should investigate the economics of dimensional standardization from the points of view of interchangeability and the elimination of unnecessary types and sizes. Commenting upon the refusal of the English-speaking countries to abandon completely the traditional and instinctive methods of subdivision in favour of the metric system, Mr. Good remarked : "This characteristic compromise is due partly to an intuitive recognition that there is much reason behind tradition and partly to an intuitive selection from alternatives of the one which most facilitates thinking processes. It perhaps also illustrates an unconscious resistance to the view that the scientist is always right and should have the last word."

Assessment of the quality of a commodity in bulk by the process of sampling is an inheritance from early trading practice which only in recent years has been developed and applied in manufacturing industry on a sound scientific basis. This development has rendered practicable the use of certification marks on goods where testing must, for one reason or another, be carried out on samples. A notable example of the successful use of a certification mark, in association with a manufacturer's mark, is the hall-marking of gold and silver articles, a practice introduced in Britain more than six hundred years ago.

The standardization and the co-ordination of the technical terms employed in science and in industry are not inconsiderable factors in the conduct of trade with efficiency and probity. The possibility of international as well as national co-operation in the introduction and definition of new technical and scientific terms is, in Mr. Good's opinion, a matter meriting the attention of the Institution of Electrical Engineers.

In the development of electrical standards, the work of the British Association in 1861 on the fundamental units was followed by the setting up in 1885 of a committee of the Institution of Electrical Engineers to prepare standards for electrical materials and appliances. This Committee was, shortly after the turn of the century, to merge its activities with those of the standardizing committees of the other professional engineering institutions in Britain to form the organisation now known as the British Standards Institution. From its inception as a body concerned with engineering standards, this body has developed into an organisation embracing within its scope practically every form of industrial activity and enabling all sections of industry to co-operate in the preparation of standards. The ideal standard should include requirements in terms of the mechanical, physical and chemical properties which can be assessed objectively ; but many of our present standards necessarily include estimations of a subjective character. The progressive elimination of such indefinite measures of quality or performance is one of the important branches of research in relation to standardization.

Reviewing the position of the electrical industry as a whole, Mr. Good remarked that he had watched its growth first from the inside and later from an external position in which he had been able to compare progress with that of other industries. "As a result", he said, "I am convinced of the truth of S. Z. de Ferranti's statement, made in 1910 and referred to in last year's presidential address, that wherever coal or gas is used for the production of heat or power, everything for which it is used would be better done were electricity the medium of application." That there will be an enormous increase in the use of electricity is certain. The electrical industry in Britain is, however, in common with others, faced with the need for planning for its future development. "This year", he went on, "has seen an Act of far-reaching importance come into being. In my opinion there is no substantial case against some form of public control of the generating and distribution side of the electrical industry, nor indeed against national control of any public service where competition is unwarrantable. This section of the industry should, however, be confined to generating and distribution and should not be permitted to manufacture the machinery or equipment it uses. A very different type of mind is required for the generating and distribution side than is required for the manufacturing side, for those responsible for running machinery and equipment have to be satisfied with it for many years, whereas the maker should be temperamentally desirous of improving his product. Moreover, a great deal of technical progress is made as a result of what might be called the 'competition' that goes on in the designer's mind in his desire to make progress."

"We are", said Mr. Good, in concluding this section of his address, "inheritors of the result of the thinking of our predecessors, and we must see to it that when our successors look back they do not detect any flagging in our efforts to give humanity the benefits that electricity alone can bring."

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, November 3

Royal Society of Medicine, Epidemiology and State Medicine Section (at 1 Wimpole Street, London, W.1), at 4.30 p.m.—Dr. E. Ashworth Underwood : "History of Cholera in Great Britain" ; Major-General Sir John Taylor : "Current Problems in Cholera Control" ; Mr. P. Bruce-White : "Bacteriological and Immunological Aspects of Cholera".

Manchester Literary and Philosophical Society (in the Reynolds Hall, College of Technology, Manchester), at 5.30 p.m.—Symposium on "Intelligence Testing in School and Work".*

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. R. C. Smart : "Industrial Organisation as a Factor in Production Efficiency".

Textile Institute (at 16 St. Mary's Parsonage, Manchester), at 6 p.m.—Mr. A. Walton : "The Artist in Relation to Textiles".

Tuesday, November 4

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5 p.m.—Hon. Camilla Wedgwood : "Trading and the Exchange of Goods on Manam Island".

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Sir Edward Salisbury, F.R.S. : "The Vegetation of the Chalk", 2. "The Biological Features of the Chalk Down Flora and their relation to the Physical and Biotic Factors".

Chemical Engineering Group (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. L. Rotherham : "The Selection of Stainless Steels for the Chemical Engineering Industries".

Institute of Physics, Electronics Group (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. J. H. Pratt : "Infra-Red Image Converters".

Institution of Civil Engineers (at Great George Street, London, S.W.1), at 5.30 p.m.—Sir Roger Hetherington : Presidential Address.

Institution of Mechanical Engineers, Automobile Division (at Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—M. A. Jullien : "Independent Suspension Systems".

Sheffield Metallurgical Association (joint meeting with the Iron and Steel Institute, at 198 West Street, Sheffield), at 7 p.m.—Mr. C. Sykes, F.R.S., Mr. H. H. Burton and Mr. C. C. Gegg : "Hydrogen in Steel Manufacture" ; Prof. J. H. Andrew, Mr. H. Lee, Mr. H. K. Lloyd and Mr. N. Stephenson : "Hydrogen and Transformation Characteristics in Steel".

Wednesday, November 5

Institute of Fuel (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 2.30 p.m.—Mr. Donald Hicks : "The Coal Resources of the Country".*

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Sir Harry Lindsay : "Cultural Relations within the British Commonwealth".

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Dr. G. D. Reynolds : "Tests for the Selection of Components for Broadcast Receivers".

Society of Public Analysts and other Analytical Chemists (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Scientific Papers.

Manchester Metallurgical Society (at the Engineers' Club Albert Square, Manchester), at 6.30 p.m.—Mr. E. Jones: "Electrical Strain Gauges".

Royal Statistical Society, Birmingham Group of the Industrial Applications Section (in the Chamber of Commerce, 95 New Street, Birmingham), at 6.30 p.m.—Mr. L. T. Wilkins: "Methods of Forecasting and Preventing Accidents".

Institute of Welding, Manchester and District Branch (in the Reynolds Hall, College of Technology, Manchester), at 7 p.m.—Mr. H. E. Lardge: "Welding in the Development of Jet Propulsion Engines".

Society of Instrument Technology (joint meeting with the Society of Glass Technology, in the Lecture Theatre, Science Museum, South Kensington, London, S.W.7), at 7 p.m.—Discussion on "The Instrumentation of Glass Tank Furnaces" (to be opened by Mr. H. L. Crooks and Mr. C. H. Stone).

Thursday, November 6

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Special General Meeting to consider a proposal by Council for the alteration of Statute 23; Dr. H. R. Ricardo, F.R.S.: "Some Problems in connexion with the Development of a High-speed Diesel Engine" (Bakerian Lecture).

Mineralogical Society (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. C. N. Cock: "Electric Traction on the Southern Railway".

Chemical Society (in the Chemistry Lecture Theatre, University College, Nottingham), at 6 p.m.—Prof. F. S. Spring: "Some Contributions of the Organic Chemist to Biological Science".

Illuminating Engineering Society, Manchester Centre (joint meeting with the North-Western Branch of the Institution of Electronics, in the Reynolds Hall, College of Technology, Manchester), at 6.30 p.m.—Dr. J. N. Aldington: "The Evolution of an Electric Lamp".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Scientific Papers.

Royal Institute of Chemistry, London and South-Eastern Counties Section (at the South-West Essex Technical College, Forest Road, Walthamstow, London, E.17), at 7.30 p.m.—Scientific Film Display.

Chemical Society (in the Chemical Department, The University, Woodland Road, Bristol).—Prof. R. D. Haworth, F.R.S.: "The Oxidation of Phenols".

Friday, November 7

Association of Applied Biologists (in the Botany Lecture Theatre, Imperial College of Science, South Kensington, London, S.W.7), at 2.15 p.m.—Dr. A. C. Evans: "The Biology of Earthworms and their Effects on the Soil".*

Bedson Club (in the Chemistry Lecture Theatre, King's College, Newcastle-upon-Tyne), at 5.30 p.m.—Prof. H. Bassett: "Pages from the Chemistry of Aluminium" (Sixty-seventh Bedson Lecture).

Institution of Electrical Engineers, Measurements Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "Telephone Cable Measurements" (to be opened by Mr. S. Hanford).

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Discussion on "The Measurement of the Temperature of Sliding Surfaces, with particular reference to Railway Brake Blocks" (to be opened by Dr. R. C. Parker and Dr. P. R. Marshall).

Royal Statistical Society, London Group of the Industrial Applications Section (joint meeting with the Institution of Engineering Inspection, at the E.L.M.A. Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 6 p.m.—Mr. D. Newman: "Acceptance Inspection with special reference to Sequential Methods".

Geologists' Association (at the Geological Museum, Exhibition Road, London, S.W.7), at 6.30 p.m.—Annual Re-Union.

Oil and Colour Chemists' Association, Manchester Section (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Discussion on "Surface Activity".

Society of Chemical Industry, Manchester Section (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Prof. E. C. Dodds, F.R.S.: "Academic Research and the Chemical Industry".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. E. K. Rideal, F.R.S.: "Foam".

Chemical Society (joint meeting with Cambridge University, in the University Chemical Laboratory, Cambridge).—Prof. C. N. Hinshelwood, F.R.S.: "A Problem in Chemical Kinetics".

Saturday, November 8

Physical Society (in the Physics Department, University College, Nottingham), at 10 a.m.—Scientific Papers.

Institution of Chemical Engineers, North-Western Branch (in the Reynolds Hall, College of Technology, Manchester), at 3 p.m.—Mr. A. L. Curtis: "Modern Tar Distillation Plant".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Laboratory Steward to take charge of the maintenance of the teaching and research laboratories of the Chemistry Department—The Bursar, The University, Sheffield (November 8).

Lecturer in Chemistry (Ref. F.886/47A), and a Lecturer in Physics (Ref. A.391/47A), at the Royal Aircraft Establishment Technical College, Farnborough—The Ministry of Labour and National Service, Technical and Scientific Register, Room 669, York House, Kingsway, London, W.C.2, quoting the appropriate Ref. No. (November 8).

Principal of the Luton Technical College—The Director of Education, Shire Hall, Bedford (November 8).

Lecturer in Mechanical Engineering—The Principal, Brighton Technical College, Brighton 7 (November 8).

Teacher in Biology at Canterbury Technical College and County Technical School for Boys—The Education Officer, 78 London Road, Canterbury (November 8).

School Psychologist—The Director of Education, Education Department, Pontmorlais, Merthyr Tydfil (November 8).

Lecturer in Mathematics, and a Lecturer in Chemistry, at the North Gloucestershire Technical College—The Clerk to the Governors, The Lypiatts, Lansdown Road, Cheltenham (November 8).

Senior Research Officers (2) with the Social Survey Division of the Central Office of Information—The Ministry of Labour and National Service, Appointments Department, Technical and Scientific Register, Room 669, York House, Kingsway, London, W.C.2, quoting G.471/47A (November 10).

Principal of the Technical College to be established in Chippenham—The Director of Education, County Hall, Trowbridge, Wilts, endorsed 'Chippenham Technical College' (November 10).

Agricultural Economist, and Assistant Agricultural Economists (2, Grade B), to work under the direction of the Provincial Agricultural Economist at Newton Abbot—The Registrar, The University, Bristol 8 (November 10).

Research Chemist for work on soils, with headquarters at Auchincruive—The Secretary, West of Scotland Agricultural College, Blythswood Square, Glasgow C.2 (November 14).

Assistant Lecturers in the Department of Physiology (one will be mainly concerned with Histology)—The Registrar, The University, Liverpool (November 15).

Research Fellow to work in the field of intermetallic friction under conditions of plastic deformation in metal-working processes—The Professor of Industrial Metallurgy, The University, Edgbaston, Birmingham 15 (November 15).

Research Officers (2) in the Division of Electrotechnology, Sydney—The Secretary, Australian Scientific Research Liaison Office, Australia House, Strand, London, W.C.2, quoting No. 1402 (November 22).

Principal Scientific Officer or Engineer I at the National Gas Turbine Establishment under the Ministry of Supply—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2027 (November 28).

Lecturer or Assistant Lecturer in Zoology (preferably with special knowledge or qualifications in Vertebrate Zoology)—The Registrar, University College, Southampton (November 30).

Principal Scientific Officer in the Armament Design Department (Unguided Rocket Design Group), a Principal Scientific Officer in the Armament Design Department (Central Technical Group), and a Principal Scientific Officer or Senior Scientific Officer in the Armament Research Department, under the Ministry of Supply—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2024 (December 5).

Electrical Engineers for the Electricity Department of the Malayan Union—The Director of Recruitment, Colonial Service, 15 Victoria Street, London, S.W.1.

Senior Lecturer in Agriculture, and a Resident Assistant Lecturer in Agriculture, at the Cumberland and Westmorland Counties' Farm School, Newton Rigg—The Director of Education, 5 Portland Square, Carlisle.

Senior Assistant Lecturer in the Department of Mechanical Engineering—The Principal, Borough Polytechnic, Borough Road, London, S.E.1.

Lecturers in (*a*) Chemistry to B.Sc. standard, (*b*) Physics to General Degree standard—The Clerk, Northern Polytechnic, Holloway, London, N.7.

Graduate Assistant Master for Physics, with subsidiary Chemistry and Mathematics, at the County Technical School—The Director of Education, County Education Offices, Newtown, Montgomeryshire.

Lecturer in Economic Theory, and an Assistant Lecturer in Psychology—The Registrar, University College, Nottingham.

Fisheries Research Officer (male or female) in Uganda—The Director of Recruitment, Colonial Service, 15 Victoria Street, London, S.W.1.

Histologist, an Embryologist, a Neuroanatomist, and a Professor of Physiology—The Medical Secretary, Hebrew University, Jerusalem, Palestine.

Senior Nutritionist or Dietist, and Laboratory Technicians (including animal attendants)—The Director, Wellcome Laboratory of Human Nutrition, Churchill Hospital, Oxford.

Technician to take technical charge of laboratory and the training of junior technicians—The Secretary, Bacterial Chemistry Research Unit, Lister Institute, Chelsea Bridge Road, London, S.W.1.

Research Worker for investigation on African Trypanosomes at Field Station near St. Albans—The Director, Department of Parasitology, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1.

Research Assistant with qualifications in physiology or zoology, at the Gerontological Research Unit—Dr. Korenchevsky, University Museum, Oxford.

Vice-Principal (woman, with qualifications in Education or Psychology), and a Lecturer (part-time, man or woman) in Biology—The Principal, City of Leicester Training College, Humberstone Drive, Leicester.

Mechanical Engineer in the Public Works Department, Tanganyika Territory—The Director of Recruitment, Colonial Service, 15 Victoria Street, London, S.W.1.

Executive Engineer for the Public Works Department, Nigeria—The Director of Recruitment, Colonial Service, 15 Victoria Street, London, S.W.1.

COMMUNICATION OF INFORMATION AND KNOWLEDGE

ALTHOUGH the meeting of the British Association at Dundee illustrated fairly enough, as it was planned to do, the great contribution which science can make to the task of building a better and a more stable world, there was easily discernible some even deeper thinking about the central issues that confront governments and peoples to-day. Some of the addresses, notably that of Prof. Dennis Robertson to Section F (Economics and Statistics), frankly challenged complacent and woolly thinking about planning and its limitations, while the presidential address itself touched on some deeper issues. When Sir Henry Dale suggested that there might be danger to science from a tendency to transfer too easily and completely, to the activities of peace, the attitude to research and the traditions of its conduct which have been acquired during six years of war experience, he was probably not thinking solely of the need of extending the fundamental investigations suspended or restricted by war, or of the trammels of scientific communication imposed by the obligations of secrecy.

Behind that plea for less secrecy and greater freedom of communication lies the much larger question of communication of knowledge in general. The threat to freedom of communication in science is only real in so far as conditions exist which threaten freedom of communication in general, and some of the sectional discussions at Dundee put this question of communication in its true light. It is a first condition of social cohesion and an essential factor in effective co-operation. It is more than the connective tissue of society; it is the nervous tissue as well.

That was well illustrated in the discussions on operational research in war and peace, on incentives in industry, and on public opinion surveys; and neglect of this factor has contributed seriously to the difficulties of Great Britain at the moment. In no department of administration has the Government more signally failed than in this matter of public relations. In one measure after another, it has not sought to secure, before introducing new measures, the full public understanding and support which are essential for the success of legislative or administrative action alike; and what the Government has not done itself, it has indirectly if not deliberately hindered the Press from doing. Few things, indeed, show up more clearly the consequences of the restrictions on newsprint than the contrast between the treatment by the Press of the Dundee meeting of the British Association and that of the last full meeting of the Association before the War. Limitations of space have prevented any reporting at all of numerous important discussions, and in consequence the educative value of the meeting has been more severely restricted to those present than at any time in the last century.

It is a further sign of the Government's ineptitude in the matter of communication, in spite of lip-service to the support and spread of scientific knowledge, that this moment should be chosen to re-impose the licensing system for the import of books; a measure which proved such a serious handicap to scientific and technical men during the War. Leaving on one side for the moment the consideration of the cultural aspect of this hindrance to the interchange of ideas and thought, at a time when the United Nations Educational, Scientific and Cultural Organisation is endeavouring to remove such obstacles, the restoration of a licensing system will put a new obstacle in the way of research workers obtaining the tools they need. Government policy, as well as the consequences of our own war effort, have concentrated the production of new scientific and technical books in overseas hands, largely in the United States; consequently, an immediate and indirect effect of the new Board of Trade order will be to hinder the increased industrial efficiency and development which the Government wishes to promote.

Such checks on discussion and communication are, in fact, much more serious than the limitations imposed by secrecy obligations, for example, in regard to atomic energy. No one can suggest that, in this field, Great Britain or the United States can disregard the implications of the new law in the U.S.S.R. regarding official activities; but in the atomic energy field it is the risk of administrative stupidity or incompetence in the administration of the Atomic Energy Act that lies at the root of any real fears as to its effect on the interchange of scientific knowledge, as distinct from the technical information relating to military applications. No well-informed person to-day will support the suggestion that the great bulk of industrial research work that is of scientific interest is not now published. British industry is now in no way behind American industry in this respect. It might even be held that it is in advance, in that more discrimination is exercised and negative results of no scientific significance do not clutter the pages of British scientific periodicals. The limiting factor is not the restraint on publication exercised by the industrial firm, but the reluctance or inertia of the scientific worker himself in the matter of preparing his results for publication before proceeding with further investigations.

Although, therefore, the secrecy threat to freedom of communication in science is apt to be overstressed, it cannot be denied that the existence of the new Russian law on the disclosure of State 'secrets', with its wide implications and restraints over the whole of industry, agriculture, science and technology, is liable to provoke Government intervention in other countries also, and so hinder the full development of science. That is true in the United States no less than in Great Britain; science thrives best under the conditions of full freedom of thought and discussion which best enable us to draw collectively upon all the resources of wisdom, statesmanship and goodwill which we possess.

Some recent publications of the American Academy of Political and Social Science are of interest and importance in this connexion for the positive suggestions they contain. For example, a paper by Dr. Sumner H. Slichter, "Some Economic Consequences of Science" (*Ann. Amer. Acad. Pol. and Soc. Sci.*, 249, 99; 1946) directs attention to the importance of extending our knowledge of techniques available for diminishing controversy and increasing the use of co-operative attacks upon problems, and of the conditions which determine the capacity of individuals to participate intelligently in the affairs of the community and to supervise effectively their representatives responsible for making and executing policies. Progress in these two fields would enormously increase the capacity of the community to serve its problems and to adjust itself to changes. The formulation of specific programmes in these fields is the task of the social scientist, and Dr. Louis Wirth also contributes a valuable paper on the "Responsibility of Social Science", in which he discusses the reasons for the failure of social science to gain wide public acceptance, and reports on the conditions required to enable research in social science to make its full contribution to the solution of problems arising out of the impact of science upon society. Significantly enough, Dr. Wirth himself suggests that such research will be inadequate unless it includes the search for knowledge on power relations among men, and the means for generating the will and the capacity for action directed toward the achievement of a good society. The social scientist is, in fact, coming to recognize the importance of investigating just those fields to which the economist is directing attention in considering the limitations of social and economic planning; while psychologists themselves, as Prof. Donald C. Marquis shows in a paper on "Psychology of Social Change", are approaching the many problems opening up in the field of communications as it bears on social therapy and the establishment of international as well as national or industrial understanding and order. The accurate measurement at frequent intervals of the status of public opinion on international questions; the study of the basis of such attitudes by examining their relation to the quantity and kind of information held by the individuals, and their relation to other attitudes, convictions and individual traits; and the study of the means of reaching and affecting people individually and in groups—all these are fields in which Prof. Marquis believes research could yield most fruitful results.

The improvement of means of communication of information is a first responsibility, and important as it may be to improve and extend what is generally known as public relations work in respect of the flow of information, both to the public, and also to the Government as regards the trend of opinion, and for research in this field, the first task is the elementary one of securing that there is no impairment of the established channels while the new techniques—classroom communication and group discussion, the use of radio, the motion picture and advertising, or what E. L. Bernays terms the engineering of consent—are being explored and developed.

These possibilities are well brought out in the series of papers issued by the American Academy of Political and Social Science (*Annals*, **248–251**), which touch, too, on those problems in the relationship of management and labour involved in the use of such bodies as the production committee or works council as means of communication. But no one who studies this symposium of papers, thinking of the avenues of sociological research which they indicate, will be led by that vista to forget the elementary duties which lie to hand for every responsible citizen. We must, indeed, improve our channels and means of communication in both directions, alike between Government and governed, manager and operative; but above all, as Prof. Williamson and the Hon. Karl E. Mundt both indicate, we must so far as is possible replace Government control, direct or indirect, over sources of information and means of communication, by the conscious and spontaneous self-control exercised by those who recognize that a great social system can only be built on rational action and on some sacrifice of personal interest to the welfare of the community.

There are old as well as new techniques which can be used to enable the community to understand the need for this sense of social responsibility. There is no greater danger to a free people than that of dictation or of neglect by the Government to dig deep the channels of assent to legislative or administrative action. The papers in these volumes from the American Academy of Political and Social Science, as well as the discussions at the Dundee meeting of the British Association, demonstrate how grave is the situation and how important it is that further research into this question of communication, its techniques and organisation, should be pressed forward from the point of view of production and national recovery. They show also that all men of goodwill should unite to resist the encroachments on the old freedom of thought and utterance which war-time practices and administrative ineptitude are still making, both in the field of science and in the world at large.

THE PREDICTION OF NATURAL FREQUENCIES OF VIBRATION

The Escalator Method in Engineering Vibration Problems

By Joseph Morris. Pp. xv + 270. (London: Chapman and Hall, Ltd., 1947.) 21s. net.

THE problem of calculating the natural frequencies of a dynamical system is of considerable technical importance in many branches of engineering and not least in that branch of engineering called instrument-making. It is important for the designer to be able to predict natural frequencies for two main reasons. First, in order to avoid the occurrence of resonance, that is, agreement of a natural frequency with that of some periodic forcing agency; this is of particular importance in rotating and reciprocating machinery, where persistent resonance in service is dangerous. Secondly, in instruments where response and stimulus should be linearly related over a band of frequencies, approach to resonance cannot be allowed, as this destroys the required characteristic. All this is true of electrical and of electro-mechanical systems as well as of purely mechanical ones.

The main purpose of the book under review is to put forward a method for calculating the natural frequencies and modes of systems having a finite number of degrees of freedom, or which can be represented as such. The special feature of the method, which is indicated by the word 'escalator', is that the solution is worked out in a succession of steps in each of which the number of degrees of freedom is one greater than for the previous step, until the full number in the system is attained. Determinants are not used, and the equations determining the frequencies and modal ratios at each stage are easily constructed from the results obtained at the previous stage.

The reviewer believes the method to be new, and the examples included in the book amply demonstrate that it is workable and useful in the hands of an expert. Whether the inventor's great enthusiasm for the method is fully justified only experience can settle. Undoubtedly the method is particularly well suited to those problems where most of the dynamical system is constant but where parts of it are subject to variation, for it may be possible so to arrange the calculations that the variable elements only appear in the last stages of the 'escalator'. When this is so, considerable saving in labour may result. It is just on the question of economy of labour for results of given accuracy that the method must be judged, as it has no advantage of elegance and, of course, it yields theoretically the same results as orthodox processes. It should be added that the special advantage just mentioned is not peculiar to the Morris escalator; it is shared to some extent, for example, by the method of partition or of sub-matrices.

The contents of the book are considerably wider than the title would indicate, for the first seven chapters are devoted to discussions of problems in the statics of beams and structures. A welcome feature is the inclusion here of a chapter on the Hardy Cross method and some of its extensions, but the author does not remark the fact that all such methods are essentially the same as the Gauss–Seidel method for the iterative solution of simultaneous linear equations. Applications of the escalator process, for the most part to problems arising in aeronautics, occupy the last eleven chapters.

Unquestionably the author has written a stimulating and useful book which embodies the results of many years of enthusiastic work, and he is to be congratulated on bringing this to fruition. The reviewer must express his regret that the author has never adopted the notation of matrices in his work on vibrations and structures, since the gain in clarity and conciseness is enormous. W. J. DUNCAN

THE FINAL INTEGRATION

The Integrative Action of the Nervous System

By Sir Charles Sherrington. With a new Foreword by the Author and a Bibliography of his Writings. Pp. xxvi+433. (Cambridge: At the University Press, 1947.) 25s. net.

IN July the seventeenth meeting of the International Physiological Congress was held in Oxford. It was the first since the meeting at Zurich in 1938, and like other post-war congresses it was a most enjoyable reunion. The organising committee had many problems to face in planning for a meeting with an attendance of 1,300; but at least it had no difficulty in choosing an appropriate gift to the members. What was needed was some classical English work on physiology; for a congress at Oxford, therefore, what better choice could have been made than a new edition of Sherrington's Silliman Lectures, "The Integrative Action of the Nervous System"? This famous book was published in 1906: it laid the foundations of the neurophysiology of the brain and spinal cord as we know it to-day, and though it has been out of print for some years it is still an essential introduction to the study of the central nervous system.

The Yale University Press, the original publishers, kindly allowed the Physiological Society to bring out a fresh edition. The preparation was entrusted to Prof. Samson Wright, and all physiologists and neurologists will be grateful for what he has done. The text is reproduced without alteration; but the blocks have been redrawn, a bibliography and a photograph of the author have been added, and, best of all, a foreword by him specially written for this edition. In it Sherrington has given us his mature judgment on the wider issues raised by his work. By isolating the spinal cord from the dominance of the brain he was able to analyse the mechanism of simple reflex behaviour. In the brainless animal we study the automatic responses of a 'Cartesian puppet', and the simple reflexes give the clue to its nervous machinery. They are, for the most part, convenient experimental abstractions; they have been most valuable in understanding the integrated behaviour of the whole organism, but clearly they are not enough. In man at least we shall never understand behaviour unless we bring in mental as well as physical events.

In "Man on His Nature", Sherrington has dealt with this cardinal problem of neurology, and in these twelve introductory pages he returns to the theme, stressing the difficulty of welding together the two incommensurables, the physical and the psychical series of events. The liaison between them is a problem still unsolved, remaining where Aristotle left it more than two thousand years ago; but Sherrington's discussion of "the last and final integration" gives it physiological as well as philosophic interest. Though the duality remains we can face it more boldly when we think of the amazingly complex adjustments which the mindless animal can carry out.. Indeed, when we consider the behaviour of a series of animals with more and more elaborate nervous systems, it would be quite impossible to say where psychical activity begins. It is present in man at all events, and the final chapter in Sherrington's book points the way to its study in terms of the physical apparatus of binocular vision.

The experiments on reflex activity described in the earlier chapters were made at a time when the graphic recording of muscular contraction was the most accurate method of following the time course of spinal excitation. Nowadays, electrical methods give a precision reckoned in tenths of milliseconds instead of tenths of seconds. The finer details of the reflex arcs have been explored and the literature of synaptic conduction would run into volumes. Yet Sherrington's work remains the framework for any detailed picture of nervous integration; what he describes as his "rather elderly volume" has lost none of its vitality. It is a work which British physiologists were proud to give to their colleagues in celebration of the Oxford congress.

E. D. Adrian

THORPE'S DICTIONARY OF APPLIED CHEMISTRY

Thorpe's Dictionary of Applied Chemistry

Fourth edition, revised and enlarged. Vol. 7: Iodazide—Metellagic Acid. With an Index by Dr. J. N. Goldsmith. Pp. xii+629. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1946.) 80*s*. net.

THE third edition of "Thorpe" originally ran into seven volumes. The fourth, in the same span, takes us only halfway through the alphabet, and if the standard were maintained (and it can be stated forthwith that it is) on simple proportion we might expect it to be twice as useful. In fact, the ratio is even higher since, with the exception of a few short items, mainly on minerals, the whole of the subject-matter has been rewritten, only the more important parts of the older material being retained and incorporated with the new matter. Merely to browse through this book is a most salutary proceeding for, apart from inducing a fuller appreciation of all the work that has been involved in the production, it brings home with a startling jolt how much there is that one does not know. It follows that, when in search of a piece of information, it is wise to "look it up in Thorpe" first. Of course, the answer is not always there; no one book or set of books could contain all the answers; but the state of the volumes of "Thorpe" after several years in a library or general laboratory is a dumb token of appreciation.

One of the fascinating features of "Thorpe" is the width of the net which it casts. No better example of this could be given than the article on 'Lichen Substances'. This is an interesting group if only because it contains the few naturally occurring organic compounds containing chlorine so far known; but also it is one which does not reach the limelight to the same extent as some other plant products such as the alkaloids or the essential oils with their more practical applications. That the subject is not overlooked by chemists is clearly indicated by the extension which has been called for in the revised article. The lactones form another group well represented in Nature, but these have spread through commercial demands for coumarin and undecalactone, to mention just two, into the realm of the chemical works. Butyrolactone comes within the range of Reppe's acetylene programme; but it is rather early for the information on this remarkable work to have penetrated beyond the special reports thereon.

As a good example of the appreciation (using the word in both senses) of values, the subject of lignin, formerly dismissed in a few lines, is now allocated more appropriate space in view of recent developments, particularly in the United States. The new article on meat extract presents a very fair picture of a subject on which there has been much divided opinion.

In accordance with the expressed policy of the new editorial board of extending the increasingly important physico-chemical subjects, topics such as magneto-chemistry, mass spectra, membrane equilibria, luminescence, mesomerism, liquid crystals, structure of liquids are dealt with at some length. No one, least of all the authors, would claim that these articles are a complete guide to the subjects, but further guidance is given by the inclusion of extensive bibliographies. Among the smaller contributions of this type may be mentioned isoelectric point, lyotropic series, Kerr constant, ionization potentials, isochore and Joule's equivalent.

The general treatment of such of the elements as fall within the literal scope of this volume follows the familiar lines of describing, as appropriate, occurrence, extraction, refining, physical and chemical properties, uses, alloys and compounds, both inorganic and organic; naturally one does not expect to find here all the minutiæ given in "Mellor".

Some disappointment was felt at the lack of detail on the nature of additives for lubricating oils; but, in fairness, it must be admitted that a plea of extenuating circumstances can justifiably be made. On one hand, the number of compounds which have been proposed for the purpose is enormous, while on the other, commercial reticence about those which are actually used is natural enough; moreover, it is doubtful whether the precise nature of some of these products is known.

It would be an invidious task to quote names of contributors; suffice it to say that they are such as to command the respect due to authority in their various fields. On the material side, the now familiar jacket of blue is maintained undimmed, but the stringency of the paper position is reflected in an irregular alternation of colour coupled with quality. The paper is adequate, but it is to be hoped that supplies of at least a uniform tint will be available for subsequent volumes. However, better a "Thorpe" in cream and white rather than no "Thorpe" at all.

B. A. Ellis

SOCIAL IMPROVEMENT BY EDUCATION

Some Tasks for Education

By Sir Richard Livingstone. Pp. vii+98. (London, New York and Toronto: Oxford University Press, 1946.) *5s.* net.

THE four lectures in this volume were delivered in September 1945 at the University of Toronto—the first three on the Burwash Foundation and the fourth as the Sir Robert Falconer Memorial Lecture. Although they are not consecutive, all deal with aspects of a single problem—how to improve ourselves and our society by education—and are a valuable corrective to the current obsession of educationists for dealing with means rather than ends. Those who are familiar with Sir Richard's earlier writings will not be surprised to find that, although he examines proposed revisions of curricula to meet the needs of the modern world, he is chiefly concerned to emphasize, as the prior task of education, the need "to inspire and to give a sense of values and the power to distinguish what is first-rate . . . from what is not". "It is", he declares, "right to teach the pupil to criticize, but it is even more important to train him concurrently to admire." To him "nothing—not all the knowledge in the world—educates like the vision of greatness, and nothing can take its place".

The most challenging passages in these lectures are concerned with the training of character. While the creation of the first-rate in art, literature, thought and science must still be—as it has been in the past—the prerogative of the few, Sir Richard has no doubt about the ability of every human being to create the first-rate in the field of character. His indictment of modern education is its failure to afford this opportunity to every individual. Is it, as he suggests, really true "that in most modern educational schemes the training of character, if not neglected, has been given a subordinate place; that we have very little, if anything, like the concentration on it in Plato's thought and in Arnold's practice?" It may well be that the only way to learn social habits is "by living a life in which such habits automatically develop", but does it necessarily follow that the training of character is difficult, if not impossible, outside the British boarding school?

Educationists who have to struggle with conditions far inferior to those found in the public schools may justifiably be irritated by Sir Richard's preoccupation with Plato, boarding schools and Periclean democracy. Nevertheless, if he is right that the British boarding school has been the finest factory of citizenship in existence, few will be able to gainsay his conclusion that "we should give to the many some equivalent of the training we have given to the few".

MATHEMATICAL STATISTICS

Introduction to Mathematical Statistics

By Assoc. Prof. Paul G. Hoel. Pp. x + 258. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1947.) 3.50 dollars.

ONE consequence of the 'export drive' in Britain is likely to be a much increased demand for the mathematical statistician in industry; unfortunately the supply of suitable people is still far too small, and this must largely be attributed to the shortage of teachers and the absence of suitable text-books. Hoel's "Introduction to Mathematical Statistics" seems to me to be an excellent work, and if only it can become generally available it may have a most favourable effect on the situation just described. In spite of the restrictive effect of the present licensing system, means should be found of introducing the book widely in Britain. Placed in the hands of any intelligent mathematical undergraduate, it will give him in a few weeks not only familiarity with the broad outlines of the subject but also a real understanding of the types of problem with which the research worker in this field is contending.

The first six chapters cover the usual introductory material, in a manner at once accurate and attractive. There follow brief accounts of a variety of more advanced topics: multiple regression, multiple and partial correlation coefficients, discriminant functions, small-sampling distributions (t, χ^2, F, the range, etc.), non-parametric methods (the theory of runs, the Wald–Wolfowitz treatment of serial correlation), χ^2 and tests of goodness of fit, the Neyman–Pearson theory of statistical tests, and the design of experiments (including notes on stratified sampling and sequential analysis). Up-to-date references, exercises both realistic and interesting, the usual tables (together with a very useful one of squares and square-roots) and a satisfactory index complete the work. Of course it is easy to ask for more; one would have liked to see some mention of cumulants, of the characteristic function, of Fisher's exact test for 2 × 2 tables, and a more adequate account of maximum likelihood estimation. But the author was probably wise in not overloading the book; it will leave many readers full of a most healthy curiosity.

David G. Kendall

Tables de constantes et données numériques

1: Constantes sélectionées, Longueurs d'onde des émissions X et des discontinuités d'absorption X. Par Y. Cauchois et H. Hulubei. Pp. 200. (Paris: Hermann et Cie., 1947.)

SINCE the publication of Siegbahn's "Spektroskopie der Röntgenstrahlen" no authoritative list of wave-lengths of X-ray emission lines and absorption edges has been published. Cauchois and Hulubei have performed a praiseworthy task in presenting these data in one volume; they give the wave-lengths in order of increasing magnitude, values of ν/R and $\sqrt{\nu/R}$, and references to original sources. An additional table gives the values for non-diagram lines (which are probably due to transitions in multiply ionized atoms), and an appendix gives the data for each element arranged in order of atomic number.

It will be seen that the book is of interest mainly to X-ray spectroscopists, and for their convenience simple multiples of the wave-lengths are also inserted in the main table. These are described as higher orders, which means that they are the wave-lengths that would be deduced if the observed lines were taken as first-order diffractions.

The authors have chosen the results of particular researches for inclusion in their tables, rather than the means of recent determinations. It is difficult to see the justification for this, when many workers have produced results of comparable accuracy. Some discussion of the whole question of accuracy would have been valuable, since X-ray crystallographers have tended to accept data given to any number of figures. It is pleasing to note that the authors have not given any *real* values (that is, first orders in their notation) to more than six figures, so that, for example, CuKα appears as 1537·40 X. instead of the usual 1537·395 X.; but one would have welcomed more discussion of this question of accuracy.

H. LIPSON

Experimental Embryology in the Netherlands, 1940–1945

By Prof. M. W. Woerdeman and Prof. Chr. P. Raven. (Monographs on the Progress of Research in Holland during the War.) Pp. xi + 132. (New York and Amsterdam: Elsevier Publishing Co., Inc., 1946.) 6.50 fl.

THIS small volume was prepared by Profs. Woerdeman and Raven during the last months of the War, with the purpose of presenting as soon as possible an account of the work which had been done in experimental embryology during the German occupation, and which had therefore remained either unpublished or at least unknown to men of science of the Allied nations. When one considers the difficulties under which the work must have been done, the record is a remarkable one. The group at Utrecht under Raven has made an intensive study of the egg of *Limnea*, a representative of the so-called 'mosaic' eggs which have been rather unfashionable experimental material in recent years. Their careful histochemical study of the process of maturation, and their description of the different plasms and their behaviour after centrifugation, may be expected to direct the attention of students of general cell physiology to the extraordinary but fascinating phenomena to be seen in the cytoplasm of egg-cells. In Woerdeman's laboratory, work has been mainly on the more classical object of the Urodele egg. Perhaps the most striking new line of attack is that opened by experiments of ten Cate in which he has shifted the time of embryonic determination relative to that of anatomical development.

Elsevier's Encyclopædia of Organic Chemistry

Edited by E. Josephy and F. Radt. Vol. 14: Tetracyclic and Higher-Cyclic Compounds, Series 3: Carboisocyclic Condensed Compounds. Pp. xx + 711. (New York and Amsterdam: Elsevier Publishing Co., Inc., 1940.) n.p.

IT is impossible to give a critical review of what, after all, is a dictionary or catalogue.

The volume at present under consideration covers all condensed-ring hydrocarbons, sterols, bile acids, sex hormones, heart poisons and sapogenins. It is claimed that the literature is covered up to the end of 1936; but in fact the book also contains many later references, going as far as 1939. We are informed that periodical supplements are to be published, and these will doubtless bring the references up to date.

The related compounds are also found in tabular summaries or charts showing their interrelationship and methods of formation. There is an excellent formula index, as well as a very complete subject index containing even such compounds as desoxytetrahydroanhydrodigitoxigenin.

From the production point of view the volume is excellent; the formulæ are very clearly drawn and the text is easy to read.

The book should be of great assistance to sterol chemists, especially those who have no access to a modern edition of Beilstein. It is a convenient source of reference to a large number of organic compounds, thus saving much time spent in searching through Beilstein and numerous abstract indexes.

The present volume is No. 14, and the price of this is quoted as in the region of 60 dollars. Subscription to this series is therefore no light matter.

Functions of a Complex Variable

By Prof. Thomas M. Macrobert. Third edition. Pp. xv + 390. (London: Macmillan and Co., Ltd., 1947.) 18*s*. net.

IT will be recalled that this volume first made its appearance in 1917. After a reprint in 1925, a second edition followed eight years later, and this was also reprinted in due course. It contained a considerable amount of additional subject-matter, occupying some fifty pages, mainly devoted to the study of special functions, and it is interesting to note that a reviewer at the time described it as a book in which the student would find just the material he required, clearly set out and with sufficient rigour for his needs, without delving too deeply into abstract theory.

No greater justification of this statement and no more convincing proof of the usefulness of the book to students of the theory of functions could be provided than the fact that the production of yet another (the third) edition has taken place in such a short space of time. On this occasion the author has again extended the scope of the work by a further twenty pages, constituting an appendix on generalized hypergeometric functions, together with another set of miscellaneous examples. Apart from these additions, the contents are identical with those of the second edition. In spite of present-day austerity, the book is well bound and clearly printed, and it seems natural to suppose that it will continue to enjoy a well-earned popularity.

J. H. PEARCE

FUNDAMENTAL PHYSICAL THEORY

CONFERENCE AT BIRMINGHAM

PROGRESS in physical theory has from time to time come to a standstill during periods in which the theory has become increasingly complex and incapable of accounting for the observed phenomena, and which have eventually been resolved by the emergence of a fundamentally new idea. Examples of such new ideas are the electromagnetic theory of light, the older quantum theory, the principle of relativity and the new quantum mechanics. The present is again a time of failure of physical theory. The impasse has lasted about ten years, but the required new idea is still lacking. It was against this background that an informal conference on fundamental physical theory was held in Birmingham during the period July 23–26. About eighty people attended, of whom some thirty came from outside Great Britain.

The discussion at the first session was opened by Prof. R. E. Peierls, who gave a review of the difficulties associated with infinite self-energies and of the attempts that have been made to overcome them. This topic occupied the conference for the first two half-day sessions, and was resumed at the final session on July 26, which had been left free from agenda. Already in classical electrodynamics infinite self-energies occur if it is assumed that electrons and protons are point charges; but with the development of quantum theory it had been hoped that they would disappear, as had other difficulties of classical physics. Such hope has proved unfounded, and, in fact, quantum electrodynamics introduces new infinities connected with fluctuations of the electromagnetic field.

Recent attempts at removing these difficulties, none of which has proved satisfactory, fall into two classes: those which try to give a consistent formalism leading to finite results without introducing a fundamental length into the basic field equations, and those that do.

Foremost in the first class is the theory of Dirac involving the so-called λ-limiting process and introducing an extra field of redundant variables. Dirac succeeds in putting into Hamiltonian form equations which in the limit give the equations of electrodynamics, free from infinite terms. The equations can be translated into quantal terms in the usual way, and when supplemented by the redundant variables, which in a formal way correspond to negative-energy photons, give rise to no divergent integrals when solutions are sought by the usual perturbation methods. The detailed physical interpretation of the formalism is not unique, but to the simpler problems it gives unambiguous answers in agreement with observation. A feature of the equations of motion of point charges is that they possess 'runaway solutions' in which the particle accelerates asymptotically towards the velocity of light. They do not correspond to real motions and can be eliminated, at least in the classical version of the theory, by postulating extra boundary conditions of an unusual type (final, as opposed to initial, conditions); but in the quantal theory this cannot be done so simply, and a difficulty appears to persist.

Along rather similar lines is the application by Gustafson and Fremberg of an analytic method of dealing with hyperbolic differential equations developed by M. Riesz. In classical theory it leads to the same results as the λ-limiting process. The application to quantum theory is claimed to give useful results; but several objections were raised in the discussion to Gustafson's arguments.

The difficulties with infinities appear to be characteristic of field theories. Attempts to avoid the field concept and revert to an action-at-a-distance description are therefore attractive. One such theory of interest has recently been proposed by Wheeler and Feynman. It involves the propagation of influences backwards, as well as forwards, in time; but with the help of a plausible assumption, namely, that all radiation emitted will eventually be reabsorbed somewhere in the universe, it can be shown to be equivalent to the field description. Although no complete quantal version of the theory exists, it was felt by several members of the conference that it would meet with essentially the same difficulties as field theory, and objections (albeit inconclusive) were raised against it on the grounds of conflict with the quantal theory of observation.

Another attempt at avoiding infinities, due to Heitler, is the so-called radiation damping theory which prescribes rules for ignoring infinite terms arising in the calculation of radiative processes by perturbation methods. Arguments were put forward during the discussion to show that the neglect of these terms in the calculation of the energy implies neglecting terms which are essential in obtaining correct answers to other problems, notably the emission of soft radiation in *Bremsstrahlung*, as pointed out by Bethe and Oppenheimer, and the propagation of light with finite velocity. A precise formulation of the rules is, in any event, lacking; they imply a division of photons into 'real' photons, and 'virtual' photons associated with the near field of a charge, a division which cannot be made unambiguously within the framework of the present theory.

It is theoretically possible to construct a field theory in which the self-energy of a singularity is negatively infinite. If it is assumed that in addition to the electromagnetic field such fields are set up by charged particles, and that they fall off very rapidly with distance so as to be negligible at atomic distances, it is possible to construct a theory which reproduces the observed forces between particles on the atomic scale, and which by suitably choosing the coupling constant of the new field cancels out the positive with the negative infinity. Such theories have been studied by Bopp, Stueckelberg, and more recently and in greater detail by Pais. Proceeding by perturbation methods, Pais has shown that the infinities in the terms up to second order can be eliminated; but it is not clear whether this holds for higher orders.

Various attempts at interpreting the results of the equations as they stand were discussed at the conference, such as by calculating finite differences between the energies corresponding to different states and similar methods. Peng has, in fact, recently claimed to show that the infinities arise from the approximation methods and are not inherent in the theory; but there are flaws in Peng's argument and his contention has been abandoned. The underlying idea of the finite difference method is the convergence of a series (or integral) formed by the difference of two series which themselves diverge; if there is a unique correspondence between terms, such a sum may be expected to have a physical meaning; but in most cases the correspondence is ambiguous and often even the difference is divergent. Particular interest attached to a letter from H. A. Bethe who had in this way calculated a correction to the fine-structure separation of the hydrogen levels in the direction indicated by the microwave observations of Lamb and Retherford.

An early theory of the fundamental length type is the non-linear electromagnetic theory of Born and Infeld. Its practical consequences are so difficult to calculate that it is not possible to say that it has been disproved, although one would prefer a simpler description of phenomena. Another approach is to introduce a 'structure factor' for electrical particles, which can be done without conflicting with the principle of relativity only by assuming that the charge density at a given time depends on the position of the particles at other times. Such a theory can be made to avoid the classical infinities and probably the run-away solutions, but no quantization has yet proved feasible.

A more fundamental change of view is contemplated in a series of papers by Snyder, who considers a 'quantized' space-time. In his theory the space and time co-ordinates are non-commuting quantities, the eigen-values of the space co-ordinates being discrete (the interval between them thereby introducing a fundamental length). The idea still needs further development; but is indicative of the radical departure from our present ideas which may be necessary.

One session was devoted to mesons. There are so many variants of the theory that it is difficult to speak of agreement with experiment, but in general it seems to be poor for scattering and *Bremsstrahlung* processes. The agreement is insufficient to indicate the value of the meson spin. That negative mesons stopped in carbon and other light elements have time to decay into electrons before being captured by carbon nuclei is an experimental result which challenges the theory. According to calculations of Fermi, Teller and Weisskopf, it is in conflict with the meson theory of nuclear forces; Bohr, on the other hand, has criticized their argument and suggests that there is no disagreement. Dr. Ferretti reported on more comprehensive calculations, which show how complicated the process of the stopping of mesons really is, and which, while very provisional, do indicate a conflict with experiment, though smaller than calculated by Fermi *et al.*

Our knowledge of mesons is still so incomplete that we do not know how many different kinds exist, nor with certainty from what particles they can be formed and into which particles they disintegrate. A report on the recent observations by the Bristol group, of mesons 'disintegrating' into other mesons, probably with the emission of another unidentified particle, and of mesons causing nuclear disruptions, was of interest in this connexion.

Two sessions were devoted to nuclear theory, including the meson theory of nuclear forces. Consequences of this theory can only be calculated quantitatively for the simplest nuclei, and agreement with experiment is poor in view of the number of variants. The theory suffers from the infinities of all field theories, which here lead to greater difficulties than in electrodynamics. There were reports on calculations of magnetic moments, photo-disintegration of the deuteron, scattering of protons and neutrons and the effect of 'tensor forces', which, generally speaking, gave vague support for certain specializations of the theory. It was clear that the time is not yet ripe for detailed calculations on complex nuclei, although one may profitably study such problems as the possible rotations of heavy nuclei, which involve only general considerations, and the regularities of nuclear spins, which are zero for all nuclei containing an even number of protons and of neutrons.

The conference was throughout kept on an informal level and owed much of its success to the organisation undertaken by members of the theoretical physics department of the University of Birmingham, and to the hospitality of the University, which not only gave financial aid, allowing distinguished physicists from abroad to be invited, but also entertained to dinner all members of the conference on the evening of July 25. The conference provided an ideal opportunity for the interchange of ideas, such as is often absent from a more formal conference, even though it made abundantly clear that the fundamental idea essential to further progress in physical theory is still lacking.

M. H. L. PRYCE

THE WORLD FEDERATION OF SCIENTIFIC WORKERS

By J. G. CROWTHER

THE World Federation of Scientific Workers was founded in July 1946. It is a natural outcome of the growth of science, and of the scientific profession, in many countries. Associations of scientific workers concerned with the problems of scientists as scientists in general, rather than specialists in a particular technique, began with the foundation of the National Union of Scientific Workers in the United Kingdom in 1918. This body was originally a trade union; but, it relinquished this status for about two decades, resuming it in 1941. Its name is now the Association of Scientific Workers, and it has more than eighteen thousand members. The success of the Association, with its young and widely varied membership, has made a deep impression in many countries overseas. Consequently, when the Association took the initiative in proposing a world federation of similar bodies, it found an enthusiastic response.

The World Federation of Scientific Workers already contains seventeen affiliated bodies in fourteen countries from all five continents. It is able to call on a very wide range of experience for advice.

The fundamental aim of the Federation is to strengthen the mutual aid and information between scientists in every country, so that the strength of the scientists in one country shall be the strength of all their colleagues throughout the world. It is hoped to further through the Federation the achievement of agreed opinions on those questions which affect all scientists alike, irrespective of their speciality. In this way the scientists of the world will be able to speak with one voice on matters that affect them fundamentally. Towards this end the Federation is preparing a Scientists' Charter, defining the duties and rights of scientists, which should be observed in all countries. In every place, it will be possible to compare the actual situation with that given by the Charter, and thus assist scientists everywhere with a guide to a proper status for science and scientists. The standards of education, remuneration, working conditions, opportunities for work, and the control and direction of science vary greatly over the surface of the globe. Scientists have special knowledge of science, and in virtue of this they have the responsibility of seeing that the public is correctly informed on scientific matters which affect public affairs.

The World Federation seeks to keep in touch, and collaborate, with other international bodies concerned with science, such as the United Nations Educational, Scientific and Cultural Organisation, and the World Federation of Trade Unions. U.N.E.S.C.O. has already invited the Federation to send an observer to one of its panels, and it has invited the Federation to send an observer, subject to confirmation by the Conference itself, to the present U.N.E.S.C.O. Conference at Mexico City.

Another direction in which the World Federation has been able to contribute towards international understanding between scientists is in collaboration with other scientific bodies in the commemoration of scientific personalities and events of international significance. It joined with the Association of Scientific Workers and the Society for Visiting Scientists to organise meetings in memory of Paul Langevin, and it has joined with the Association des Travailleurs Scientifiques and the Syndicat National de l'Enseignement Supérieur et de la Recherche Scientifique in organising, under the patronage of the President of the French Republic and the Académie des Sciences, a meeting in Paris in commemoration of the tenth anniversary of the death of Lord Rutherford. The occasion will be an opportunity for remembering the great physicist, and reflecting on what has come of his work, and that of his colleagues in physics. A special feature of these meetings is that they have been organised primarily by the scientists of one country in celebration of the achievements of a scientist of another country, and have thus contributed towards the strengthening and understanding of mutual dependence and sympathy in science.

The president of the World Federation of Scientific Workers is Prof. F. Joliot-Curie, and its registered headquarters are in Paris. French-speaking inquirers can most readily receive further information about the Federation from the Secrétaire Général, 47 Boulevard St. Michel, Paris V, and English-speaking inquirers from the Secretary-General, 15 Half Moon Street, London, W.1.

THE PAINT RESEARCH ASSOCIATION

By Dr. L. A. JORDAN

Director

THE co-operative industrial research association movement in Britain is an interesting development, whatever may have been said or written about it, particularly during the last few years. Those responsible for controlling the work of the associations and of holding together on a voluntary basis a heterogeneous membership with varied views as to what co-operative industrial research is about, are conscious of the limitations and have no illusions about the weaknesses of the system. They have the responsibility of watching the interests equally of all their members; no duty could be more difficult, and errors of judgment are not lightly tolerated. Displeasure, however transient, saps enthusiasm, without which nothing is achieved; on the other hand, confidence is a plant of slow growth, but it is essential and it can be won.

One must admit that the crux of the matter, or at least one aspect of it, is the interpretation placed by individuals on the word 'co-operative' and how it is related to the primary and universal human instinct of self-interest—which may come to be regarded as self-preservation. Research work is not the only human activity in which it must be recognized that there are degrees in co-operation, and that it does not do to strain even the best of good intentions. Fortunately for research association work, many industries have a wide background of technology waiting for first-class scientific investigation from which information may be gained acceptable to all, provided it is brought only to a certain stage. That stage is when each member firm according to inclination and capacity can take the material information offered and develop it within the ambit of the firm's interest.

Inevitably that stage is too far for some—or at least they think so; definitely not far enough for others, and certainly not far enough to ensure a widespread, rapid and effective absorption of research results into the technical administration of the industry. How to deal with that problem may give rise to differing opinions and to much honest doubt. The uneasiness so frequently expressed about the research association movement is justified in so far as it is prompted by concern as to whether means can be found to give a better overall performance, meaning the integration of the results of scientific work plus development plus utilization by the greater part of an industry.

In the meantime, while such problems are being resolved, directors of research associations have to operate the instrument provided and, coming down to a homely metaphor, the 'proof of the pudding' test still holds. If one is so minded, many quite logical and apparently sound reasons can be found why the research association idea should not work out in practice; but, in fact, the associations have not done too badly. As with most human enterprises, everything turns upon the degree of satisfaction accorded to the participants, not the least important, particularly in time of war, being the State. It is true to say that had the research associations not existed in 1939, Britain would have lacked a very powerful weapon; for the associations made it possible to mobilize at short notice in industry by industry most of the scientific and technical knowledge available, and they provided facilities for the immediate investigation of new problems under most favourable conditions.

In a number of cases, particularly those concerned with the traditional industries, associations were not easy to start; thus it was not until 1926, that is, ten years after the movement began with the establishment of the Department of Scientific and Industrial Research, that the Paint Research Association was formed. The term 'paint' in this context includes colour (that is, pigments), varnish, printing ink, certain aspects of linoleum—in fact, all those procedures which depend upon a related technology of incorporating a solid into a fluid medium.

It is pertinent to ask what the Association has done during its twenty-one years and what it proposes to do—two questions which can be taken together in so far as they can be dealt with adequately in this short statement. First, there has been too great a tendency to judge research associations by the flashing discovery that solves all problems. That sort of thing is good publicity while it lasts, but is erratic in its incidence; and industries vary in the opportunities they provide for that type of work. Even so, the impression left on the collective business mind is not likely to be as lasting as the proud inventor thinks is justified.

The real need is to make and hold satisfied customers who tell their friends, and that means good nourishing fare, regularly supplied; if some special treat can be provided occasionally, so much the better. The rhythm of the Paint Research Association has been steady rather than spectacular. Much diffused information on many subjects has been brought together and records annotated, interpreted, presented and used with satisfaction. A goodly portion of the scientific background of the industry has been filled in effectively, and thereby some relief has been given to the pains of scientific indigestion, arising from the flood of new chemical substances which find uses as bases for paint materials. The volume of investigational work incidental to the provision of substitutes (to use the current phrase), better described as the proper utilization of available materials, particularly during and since the War, has been very large indeed; and some useful items have been discovered in the process. The resources of the Association have been spent, for the most part, in carrying out scientific work in the laboratory on subjects (of which an indication will be given later) arising out of problems, both short-term and long-term, peculiar to the industry.

Many factors have operated everywhere during the last generation to affect the outlook of the paint and related industries; the British industries have been greatly altered as a result of research association activity. No claim is made about monetary savings arising out of the adoption of some specific process, because we have not operated that way; yet it must not be assumed that members of the Association have not benefited financially. Indeed, not a few manufacturers admit to new and profitable procedures having been developed by them as a result of direct advice from the staff, or by utilizing hints and recommendations in technical papers.

Two years ago, a survey of the problems of the paint and allied industries was made which presented a conspectus of the field of interest, with a shorter list of collateral studies in related fields entitled "Investigations at Present Envisaged", on the basis of which work is proceeding as circumstances permit. At the same time, appropriate reference was made to matters which had already occupied the attention of the research staff to such an extent as to have resulted in a technical paper or other publication on the subject. The number of such references is impressive.

It is usual to think of paint in terms of its colour, and that means the pigment which often gives the name to the paint. A solid powder in a liquid does not necessarily make paint, and it is reasonable to accept the view that much of scientific and technical interest is to be found in the conditions operating at the interface between the pigment and medium constituting a paint—such as the wetting and dispersion of pigments, properties which must be evaluated and assessed, or the manner in which the rheological properties and other characteristics of paints are influenced by pigment/medium volume relationships and by physical factors, that is, actual physical form and surface condition, the volume and packing characteristics and the state of flocculation of the pigment. These things, among others, determine the nature of the liquid paint, its behaviour on storage (settlement, skinning, etc.), its behaviour in use (brushing quality, opacity, spreading power, etc.), its film properties (gloss, colour, hardness, resistance and sensitivity to water attack, permeability, rust inhibition, etc.) and durability which in the first instance largely depends upon adhesion to the support. All this is not due alone to interfacial conditions; but they are very important.

The different methods of application of paint and varnish and the nature and preparation of the surface of the material painted (metals, plaster, various woods, and now plastics), the manner and mechanism of film formation, the physical relationships between coats in multiple-coat films and the significance of such matters as threshold film thickness, pigment particle and molecular orientation, are all important aspects of study, as is evidenced by the large number of technical papers and research memoranda issued, approximately 150 of each. A few of these papers, dealing with "Priming of Joinery Timber", "Painting of Plaster" (from the Building Research Station), "Painting of Non-ferrous Metals", "Preservation of Iron and Steel by means of Paint", have been available to the general public. Perhaps the most notable contribution of the Paint Research Association to public papers is the book entitled "Painting of Buildings", No. 5 in the Post-War Building Series (H.M. Stationery Office); also an important contribution has been made to the Building Research Station reports on the repair of damaged buildings.

In addition to the rather general observations made above about work relating to paints and paint application, there are seven other sections into which the technology of the related industries is divided for convenience in presentation; namely, oils, varnishes and resins, pigments and chemical colours, cellulose and other lacquers, testing, bitumens, blacks and pitches, and anti-corrosion.

Oil to the paint industry, of course, means the natural drying oils and mainly linseed oil, which is still, as it has long been, the backbone of the industry. At the present time there is a good deal of publicity being given to the problem of 'substitute linseed oil', which is not an easy problem on the large scale. During the War, great efforts were made to produce, by treatment and manipulation of other oils—castor oil in particular—a product simulating the properties of tung oil; circumstances have now changed and the urge to-day is to simulate the properties of linseed oil by treatment of one or other of the semi-drying oils. The indications are that selective solvents will permit the segregation at reasonable cost of soya bean oil, rubber seed oil or candlenut oil, and possibly others, into two fractions, one rather lower and the other correspondingly higher in iodine value, which is one of the criteria of a drying oil.

In the whole range of the drying oils, including, in addition to the types already mentioned, oiticica and various fish oils, everything depends upon treatment, mainly heat with or without air oxidation. At the far end of the treatment scale, linseed oil becomes linoxyn, the gel which is the primary linoleum base.

There are, of course, partial alternatives to drying oils, namely, materials of petroleum origin and also wool-grease; the contribution of the Paint Research Association in these fields is everywhere acknowledged.

It is most necessary in an article of this kind to avoid the appearance of a catalogue, but there are still several sections of work to which no detailed reference has been made. Nevertheless, maybe sufficient has been said to indicate that the science involved in the study of paint is profound, and that the Paint Research Association is giving it attention.

ADVANCES IN PREVENTIVE MEDICINE DURING THE WAR OF 1939–45*

By Sir ARTHUR MacNALTY, K.C.B.

DURING war-time, the risks to health are many and varied; yet the essential health services of Great Britain were maintained during the Second World War at a high level of efficiency.

Vital Statistics. The estimated mean population of persons of all ages in England and Wales was 41,246,000 in 1939 and 37,785,000 in 1944. There was an addition of half a million older persons during five years of war. The birth-rate, rising from 1941 onwards, reached 17·7 per thousand in 1944, the highest it has been since 1926, and the effective reproduction-rate came within one per cent of a full replacement standard. The death-rates have not notably increased. The maternal mortality-rate fell gradually from 3·10 per thousand total births in 1939 to the low figure of 1·92 in 1944. Through sulphonamide treatment there was a notable decline in deaths from puerperal fever and sepsis. The infant mortality-rate rose a little up to 1941, but thereafter declined, and in 1944 the rate dropped to the record figure of 45 per thousand. An outstanding feature was the low mortality of children from disease during the war years.

Infectious Diseases

Generally, the chief diseases which engaged attention during the War of 1914–18 were watched for and prevented by the same means in the Second World War. These means were the maintenance of the normal health services so far as possible; port sanitary control, which guarded against the introduction of infectious diseases from abroad; purity of the water supplies; notification of infectious diseases; hospital isolation; maintenance of adequate nutrition, etc.

Smallpox. In the six years, 1939–44, 28 cases occurred in England and Wales with three deaths, all in 1944. In Scotland there were three noteworthy outbreaks in 1942, affecting Glasgow, Edinburgh and Fifeshire. Infection of a severe type appears to have been imported from the East on a ship which arrived on May 29 at the Port of Glasgow. In all, there were 72 cases with 16 deaths. The outbreaks were speedily controlled through vaccination of patients and contacts, hospital isolation and disinfection.

Scarlet Fever. The incidence declined in the period 1939–42; it then increased to epidemic proportions in 1943, with some regression in 1944. The low fatality-rate fell still lower.

Measles and Whooping Cough. As a measure of war precaution, notification of measles and of whooping cough became compulsory in England and Wales in 1940. Measles was severely epidemic in England and Wales in 1940 and 1941; a remission in 1942 was followed by a recrudescence in 1944, when the recorded prevalence was 158,479. The deaths in the epidemic years 1940 and 1941 were only 75 per cent of the average number in the quinquennium 1935–39, and the mortality-rate in the war years was unusually low. The recorded figures for whooping cough since 1940 indicate that the incidence of the disease is on the average much less than measles. The death-rates were not unduly high. Serum therapy gives inconclusive results, and vaccine prophylaxis, at present, seems of little avail.

Diphtheria. A striking success was achieved in the prevention of diphtheria, "the killing disease of childhood". Immunization has been encouraged by the Ministry of Health and progressive local authorities for the past fifteen years. In 1914 the campaign for mass immunization was intensified, the Ministry undertaking the free provision of prophylactics. It was roughly estimated that between 55 and 60 per cent of the child population of England and Wales had been immunized. There was a notable decline alike in the incidence and mortality of diphtheria during the war years. In 1940, when systematic immunization began, there were 46,281 notified cases with 2,480 deaths; in 1944 there were 29,949 cases with 934 deaths. Diphtheria is a preventible disease, and steady continuous effort is needed to raise the general percentage of immunized children to at least 75.

Typhus Fever. From times immemorial, typhus fever has been favoured by war conditions. For this reason, the Medical Department of the Ministry of Health took special precautions against the risk of introduction of the disease into Great Britain. The Ministry also issued a memorandum on louse-borne typhus fever, and supplies of anti-typhus vaccines were provided.

During the War, medical research has greatly advanced the knowledge of typhus, its prevention and treatment. The principal method of checking an epidemic is effective delousing of the population at risk. "No lice, no typhus" remains the guiding rule. As is now well known, the new synthetic compound D.D.T. has a toxic effect on lice, mosquitoes and flies. By its use a serious typhus epidemic among the Italian population in Naples and southern Italy was speedily checked. Delousing and vaccine therapy can now speedily control an outbreak. The conquest of this dire disease is one of the outstanding triumphs of the war period.

Cerebro-Spinal Fever. That war favours epidemics of cerebro-spinal fever is due to overcrowding and lack of adequate ventilation in camps and billets, which assist droplet infection, and by movements of troops, which lead to the introduction of fresh and virulent strains of the meningococcus. From the end of 1914 until 1918, cerebro-spinal meningitis was epidemic on an unprecedented scale in Great Britain, the case mortality-rate averaging 72 per cent. In 1938 I directed attention to the maintained incidence of notifications of the disease and the increased number of Group I meningococcal infections. For these reasons I considered it probable that another period of epidemic prevalence was approaching, a forecast unhappily fulfilled. In 1940 the disease began rapidly to increase and continued to do so into 1941. The total of notifications in 1940 was nearly fourfold that of our previous worst experience in the year 1915. During 1942, 1943 and 1944, the incidence and case-mortality gradually declined. In character the disease displayed its usual severity, and in distribution it prevailed widely. Fortunately, the use of the sulphonamide drugs, and later that of penicillin, in treatment achieved the lowest fatality-rate on record; in some outbreaks the low figure of 4–8 per cent was attained. The annual fatality-rates for the period 1941–44 were, in succession, 19·5, 20·0, 23·6 and 25·6, rates which imply a saving of approximately 15,000 lives. Chemotherapy has provided a powerful weapon against this deadly disease.

---

* Substance of a Chadwick Lecture given at the Town Hall, Cheltenham, on May 22, 1947.

Malaria. Based on the work and experience of the First World War, at the outbreak of war in 1939, when the risks of malarial infection from overseas again became imminent, the Ministry of Health had an efficient organisation to hand and an expert staff conversant with the problems that were likely to arise. That these precautions achieved their aim is evident from the insignificant number of cases that occurred. This anti-malarial work has been another triumph of preventive medicine. The outlook for the conquest of malaria is promising. There are new and potent drugs ('Mepacrine' and 'Paludrine') for the prophylaxis and treatment of the disease; the employment of suppressive 'Mepacrine' in highly malarious regions has been effective in maintaining British forces in these areas in a fit condition to fight and defeat the enemy. The infective agent, the *Anopheles* mosquito, can be repelled by D.D.T., which destroys both mosquitoes and larvæ.

Acute Infective Jaundice. Acute infective hepatitis, a virus disease, has caused small outbreaks in Great Britain and extensive outbreaks among the armed forces and civilian populations in Europe and North Africa. The Medical Research Council, at the instance of the Ministry of Health and the Army Council, appointed a Jaundice Committee to investigate the disease; and to facilitate the Committee's work the Minister of Health made 'jaundice' compulsorily notifiable in East Anglia.

Scabies. Scabies had a high and rising incidence in Britain from 1930 onwards. This increase was heightened when war began, first by evacuation and mobilization, and later by overcrowding, industrial shifting of population and shortage of soap, towels, underclothing and bedding, leading to a severe and widespread epidemic of scabies. In 1941 a Scabies Order was made under the Defence Regulations which gave local authorities additional powers to deal with scabies and other verminous conditions. An advisory committee was set up by the Ministry of Health. Many local authorities took vigorous action, established scabies clinics and in some areas, for example, London, the disease was made notifiable. Special investigations were made, as the result of which benzyl benzoate has proved to be the most efficacious application.

Tuberculosis

In the First World War, there was a general rise in tuberculosis throughout Britain. The increase was mainly caused by contact infection, overcrowding and breaking down of bodily resistance to infection by prolonged physical or mental strain. These are difficult things to prevent in war-time. In 1939 the deaths from tuberculosis were 25,623; in 1941 they had risen to 28,670. The figures for the two complete war years do not include soldiers, but there was evidence for a certain increase of the disease among the Fighting Services. The figures of deaths for 1942, 1943 and 1944 showed a decline, being 25,549, 25,649 and 24,163 respectively. The most disquieting feature was that deaths among children from pulmonary tuberculosis and tuberculous meningitis increased substantially during the War. The appreciable general decline has so far been maintained, but the effects in so chronic a disease may appear later. A proportion of the deaths in the non-respiratory form are due to persons drinking infected milk.

At the outbreak of war there was a temporary dislocation of the tuberculosis services in some areas, but excellent work was afterwards done in spite of many difficulties. Evacuation, air-raids, shortage of medical officers, health visitors, nurses and of bed accommodation have all affected the normal service. The scale of rationing was regarded as adequate for the tuberculous if carefully planned as in sanatoria and hospitals. At the invitation of the Minister of Health, a representative advisory committee for tuberculosis was set up, and the Ministry gave special attention to the question of after-care. The Medical Research Council established a committee of investigation, which issued a useful report in 1942.

Recent work on chemotherapy, especially that relating to streptomycin and promin, encourages the hope that eventually a drug will be found which will destroy the tubercle bacillus in man. Miniature or indirect radiography is an important aid to early diagnosis.

Venereal Diseases

War circumstances, as is well known, favour the spread of venereal diseases, and the Second World War was no exception to this rule. The increase was most marked in females. The Ministry of Health encouraged the expansion of diagnostic and treatment facilities, and made a grant to local authorities of 75 per cent of the additional cost. Regulation 33B enabled a medical officer of health, on certain conditions, to arrange for compulsory treatment. Great advances were made during the War in the treatment of venereal diseases. Penicillin has reduced the time required for the treatment of gonorrhœa to a few days, and that for syphilis from a year to approximately ten weeks, though in both these diseases 'following-up' is essential.

Maternity and Child Welfare

Throughout the War, attention was rightly directed to improving as well as maintaining the health of mothers and young children. In the reception areas the existing health services were expanded, maternity homes were improvised, sick bays were set up for minor ailments, residential nurseries for healthy children, and hostels were provided. The existing maternity and child services, on the whole, were well maintained, and the nutrition of expectant mothers and young children was safeguarded by priority allowances of milk, cod-liver oil and vitamin supplements. All this work saw its reward in the remarkable reduction of the maternal and infant mortality-rates in war-time.

Industrial Health

In various ways the health of the industrial worker was safeguarded by the Factories (Medical and Welfare Services) Order of the Ministry of Labour and National Service, by the application of the results of medical research to his protection, and by the appointment of medical officers and nurses in armament and munition factories. There is still need for the more comprehensive development of industrial health services.

Laboratory Services

To provide a new service where needed and to strengthen existing services, the Emergency Public Health Laboratory Service was established by the Medical Research Council in collaboration with the Ministry of Health. It offered greatly increased diagnostic facilities, soon proved its permanent value and has become an integral part of the public health service of Britain. The Hospital Laboratory Service set up by the Emergency Medical Service promoted and extended pathological facilities to hospitals throughout the country. Of allied interest was the Blood Transfusion Service, controlled by the Ministry of Health and the Medical Research Council, which saved many lives of soldiers and civilians. Otherwise, the air-raid lists of fatal casualties would have been much heavier.

Nutrition

At the outbreak of war, the Ministry of Food was set up with wide executive powers for the purchase, distribution and rationing of food. Rationing was based on the principle that all the essential foods should be equally available to everyone to an extent necessary to maintain health and at controlled prices. During the War a continuous watch was kept on the nutritional state of the people. There were dietetic and clinical surveys, while the Oxford Nutritional Survey, in association with the Ministry of Health and the Medical Research Council, investigated nutritional problems and added to scientific knowledge. On the whole, national rationing worked well in an unprecedented time of great difficulty and has been an important contribution to the maintenance of good health.

Civil Defence

The emergency hospital medical organisation was designed principally to deal with air-raid casualties and to provide for an outflow of wounded from receiving hospitals in the dangerous areas to hospitals in the periphery and to others still more remote. In practice, the method proved highly successful. The emergency hospitals were also used to a large extent to accommodate chronic sick, who were found in shelters and rest centres in the London area, and for people who needed to be evacuated from the coastal areas in view of the possibility of invasion. The Civil Defence organisation of Britain stood up nobly to the enemy's repeated onslaughts. The public health and medical work done by medical officers of health, doctors, nurses, sanitary inspectors, health visitors and others was beyond all praise. For example, the bombardment of water-mains and sewers involved great risk of outbreaks of enteric disease, yet, owing to the precautions taken, no cases of enteric fever occurred which could be assigned to this cause. A high tribute must be paid to the efficiency of the ambulance service and to the courage, zeal and resourcefulness of the drivers, many of whom were young women.

This satisfactory record of national health during six years of war was a great contribution to national defence, for many wars have been lost by disease and pestilence. The conditions, under Providence, which achieved so excellent a result were: (1) the work of organised public health, environmental hygiene and the health services; (2) nutrition; rationing was ably done by the Ministry of Food with expert medical advice, and the advances made in recent years of knowledge of the adequate principles of nutrition were well utilized; (3) the special arrangements for war emergencies, air-raid precautions, the Emergency Medical Service, evacuation, the comprehensive laboratory organisation, the blood transfusion service and other triumphs of administrative and scientific organisation. Finally, the years of the War and those immediately preceding it had seen great advances in medical science, especially in chemotherapy.

NEWS and VIEWS

American Scientific Mission for London

A SCIENTIFIC mission is to be established in the U.S. Embassy in London to direct the exchange of scientific information and personnel between the United States and Great Britain. It will consist of a small group of scientific men and engineers, headed by Prof. Earl A. Evans, jun. Its activities will cover fields of organic chemistry, biochemistry, physics, biology and agronomy. Mr. John R. Steelman, assistant to Mr. Truman, in a letter to Mr. Herbert Morrison, Lord President of the Council, expressed the hope that the United States would set up scientific missions in other countries in the future. Mr. Steelman explained that the establishment of scientific missions was one of the recommendations included in a series of five reports on science and public policy which he had prepared. The principal objects of the U.S. scientific mission in London will be to facilitate the exchange of scientific personnel and information between the United States and Great Britain; to develop and maintain close personal contact with British Government agencies and other research institutions in the United Kingdom; to answer inquiries originating with the United States Government Departments and scientific agencies in the United States with respect to particular developments in Great Britain; and to stimulate exchange of scientific and technical reports.

Prof. Earl A. Evans, who is thirty-seven years of age, has been professor and chairman of the Department of Biochemistry in the University of Chicago since 1942. He is already known in Great Britain, for he worked at Sheffield during 1940–41 while holding a Rockefeller fellowship, and he is a member of the Biochemical Society of Great Britain. Educated at Johns Hopkins University and Columbia University, he joined the staff of the University of Chicago in 1937 as an instructor of biochemistry. He has carried out work on the chemistry of insulin, the intermediary metabolism of carbohydrates, and radioactive isotopes.

University College of Wales, Aberystwyth

CELEBRATIONS to mark the seventy-fifth anniversary have taken place in the University College of Wales, Aberystwyth, and have included the inaugural lecture of the session and a commemoration service, as well as a series of gatherings for athletic and social activities. The College was founded by men of great vision and faith whose first meetings were held in London in 1869 in Mitre Court and in the Freemasons' Tavern off Fleet Street. They decided to launch a scheme for the foundation of the University of Wales, and in October 1892 the present College at Aberystwyth was opened in a building designed as a hotel and beautifully situated on the shores of Cardigan Bay. Under the principalship of the Rev. Thomas Charles Edwards, twenty-five men students took arts courses; to-day there are more than 1,100 men and women in the College, drawn from all parts of England, Wales and overseas, reading science, arts, music, law and rural science. The hotel buildings have long since proved inadequate, and with the help of many private donors, the College now owns a site totalling about 400 acres, including the Welsh Plant Breeding Station, and adjacent to the National Library of Wales.

The large and distinguished gathering of old students who returned for the seventy-fifth anniversary is a testimony to the widespread influence of their *alma mater*, and there can have been few occasions when one building held such a constellation of principals and vice-chancellors as that which gathered on October 25 for the presentation of degrees, *honoris causa*. The graduands included Sir James Irvine, principal and vice-chancellor of the University of St. Andrews, and Sir Hector Hetherington, principal and vice-chancellor of the University of Glasgow, both of whom delivered addresses during the celebrations. On October 26, the commemoration service concluded with a requiem for members of the College who gave their lives in the Great War. The music, written for the occasion by the present principal and the professor of music, was sung by the College choir.

Association of British Science Writers

The Association of British Science Writers was formed on March 3. Its aims are to explain science to the general public; to further the special interests of science writers; to afford the necessary protection when required; to enable science writers to act as a body; to provide facilities, as desired by the members, for general meetings with useful persons possessing material or knowledge of general interest to the Association, or whose interest in the Association is beneficial to its aims and interests; to act, perform or prosecute any other activities from time to time, as and when considered necessary by the members or appointed committee. Membership is open to journalists in the United Kingdom who are bona fide science writers, that is, those who write about science through the media of the Press, dailies and weeklies, journals, magazines and books, etc., and who earn the major part of their income from science writing. The chairman is Mr. J. G. Crowther, science correspondent of the *Manchester Guardian*; and Mr. Maurice Goldsmith, science editor of *Reynolds News*, is the honorary secretary and treasurer. Sir Richard Gregory is the first honorary member of the Association because of the great work he has done in popularizing science. The Association also aims at setting up an associate membership to include those scientists who write regularly about science, but who do not earn the major part of their income from this activity.

Research on Toxicology

The following have been appointed by the Medical Research Council to serve on a new committee to advise and assist in the promotion of research in toxicology, with particular reference to industrial hazards: Prof. G. R. Cameron (*chairman*), Prof. J. H. Gaddum, Dr. Donald Hunter, Dr. F. C. MacIntosh, Dr. E. R. A. Merewether, Prof. R. A. Peters, J. Davidson Pratt, Dr. J. R. Squire, Dr. J. Walker and Dr. J. M. Barnes (*secretary*).

For carrying out experimental work within the field covered by the Committee, the Council has recently established at the Chemical Defence Experimental Station at Porton (Wilts), by arrangement with the Ministry of Supply, a new Toxicology Research Unit under the direction of Dr. J. M. Barnes. For clinical investigations in this field the Council already has a Department for Research in Industrial Medicine at the London Hospital, under the direction of Dr. Donald Hunter, and an Industrial Medicine Research Unit at the Birmingham Accident Hospital, under the direction of Dr. J. R. Squire. In appropriate circumstances, research in the subject may be promoted by the Council elsewhere, either within its own staff organisation or by means of grants to independent workers.

Soil Surveys in the Caribbean

At the second session of the West Indies Conference, which met in St. Thomas, Virgin Islands of the United States, in February–March 1946, the question of soil surveys in the Caribbean was considered. With the object of obtaining advice on the recommendation, the Caribbean Commission, of which the West Indies Conference is an auxiliary body, appointed a sub-committee of soil scientists representative of French, Netherlands, British and United States territories of the Caribbean and comprising Dr. H. J. Page, principal of the Imperial College of Tropical Agriculture, Trinidad (*chairman*); Mr. D. Blanche, acting head of the Agricultural Service, Martinique; Dr. J. A. Bonnet, head of the Soils Department, Agricultural Experiment Station of the University of Puerto Rico; Prof. F. Hardy, professor of chemistry and soil science, Imperial College of Tropical Agriculture, Trinidad; Dr. H. J. Müller, agricultural chemist, Department of Agricultural Economics, Surinam.

The sub-committee recommended that a Conference of Soil Scientists should be held in Puerto Rico in 1948, under the auspices of the Committee on Agriculture, Nutrition, Fisheries and Forestry of the Caribbean Research Council, for the purpose of studying systems and methods of classification and mapping of tropical soils, with special reference to the standardization of such systems and methods for use in soil surveys throughout the Caribbean region, and to carrying out such surveys as soon as possible. The proposed agenda is: (i) Presentation and discussion of collected data on soil-forming factors of the various territories. (ii) Standardization of field and laboratory methods of soil surveys. (iii) Discussion of different systems of soil classification and mapping. (iv) Formulation of a detailed regional programme of soil surveys. (v) Survey of problems of soil erosion, soil conservation and soil renovation in the different territories. (vi) Practical application of soil surveys to land utilization. It was recommended that attendance at the conference should be as representative as possible, and should include soil scientists who are specially interested in tropical soils from the above-mentioned points of view, not only from the Caribbean, but also from other countries; special reference was made to Cuba, Haiti and the Dominican Republic, and it was recommended that the Governments of these countries should be invited to send representatives to participate in the conference. The recommendations have been approved by the Caribbean Commission, and a working committee has been set up to prepare for the conference, the date of which has not yet been definitely fixed.

The Giant Panda

It has been announced by the Chinese Government that the Szechwan Provincial Government has limited the catching of pandas to one pair every five years. This regulation was made at the request of the Academia Sinica with the view of protecting this rare species from extinction. Few mammals have caused more scientific and lay interest than the giant panda (*Ailuropoda melanoleuca*, David), first made known to science when David sent skins home to France from his travels in western China during 1868–69. Several expeditions attempted to secure live specimens, and in 1937 one was exhibited by the New York Zoological Society, and in the following year another was shown in London. Their similarity to the true bears is not borne out by the skull, which resembles the raccoons, and thus the sub-family Ailurinæ of the raccoons (Procyonidæ) was created for the giant panda and the more numerous lesser panda (*Ailurus fulgens*). It is to be hoped that the lead by the Chinese Government will encourage other Eastern States to curb the activities of collectors, who are likely to exterminate animals of limited distribution.

Education and Training of Laboratory Technicians

A Committee on the Education and Training of Laboratory Technicians was set up by a conference convened in 1946 by the Association of Scientific Workers, the Association of University Teachers and the British Association of Chemists. Among the bodies now represented on it are the Institute of Physics, the Royal Institute of Chemistry, the Biological Council, the Institute of Medical Laboratory Technology and the Science Masters' Association, in addition to the three Associations that convened the conference; there are also representatives of industry and a number of senior laboratory technicians on the Committee; representatives of other organisations concerned with the problem, including the Ministry of Education, are being coopted. The chairman of the Committee is Prof. F. R. Winton and the honorary secretary is now Dr. H. J. T. Ellingham (secretary, Royal Institute of Chemistry). The attention of the Committee has been directed essentially to that important class of technicians, which includes laboratory stewards and, at the highest level, laboratory superintendents, whose work is vital to the maintenance and operation of research laboratories in industrial organisations, research associations and academic institutions and of laboratories for the instruction of students in universities, technical colleges and schools. Their work involves experience of techniques derived from a number of branches of science and technology; most of them are to be regarded not as potential chemists, physicists, biologists, etc., but as potential first-class laboratory technicians. So far, however, few courses have been provided for the training of technicians of this type, nor is there any qualification in their own field to which they may aspire. The Committee is therefore engaged in preparing syllabuses for the certificate and diploma stages of a general course of training for such laboratory technicians, based on proposals put forward by a sub-committee consisting of the laboratory technician members of the Committee. It is hoped to start a trial course early in 1948. In the meantime, it is understood that a representative group of laboratory technicians who have been associated with the work of the Committee are taking steps to constitute a professional qualifying body similar in many respects to the Institute of Medical Laboratory Technology.

Thermo-nuclear Reactions under Terrestrial Conditions

The possibility of initiating thermo-nuclear reactions under terrestrial conditions is discussed by Dr. J. H. J. Poole (*Proc. Roy. Dublin Soc.*, **24**, 71; 1946). It is pointed out that the results obtained by Atkinson, Gamow and Teller, Bethe and others, in their investigations of thermo-nuclear reactions as applied to stellar conditions, are equally valid for terrestrial conditions. In applying these results to the sea, which is the largest known source of thermonuclear energy on the earth, four types of reactions need to be considered. They are proton-proton, proton-deuteron, and two forms of deuteron-deuteron reaction. The deuteron-deuteron reaction is shown to be the most important, by comparing the values of the rate of generation of thermo-nuclear energy derived for the several reactions. The question whether it is possible to initiate and maintain a thermo-nuclear reaction in the sea is discussed by considering the case of a sphere of water in which thermo-nuclear energy is being generated and which is radiating as a black-body. It is shown that the minimum radius of such a sphere must be of the order of 3×10^6 km., so that there would seem to be very little danger of starting a world-wide explosion by dropping an atom bomb into the sea. (Dr. Poole's paper was written prior to the Bikini atom bomb tests.) If the sphere consisted entirely of heavy water, the minimum radius is reduced to 3·6 km., so that even in this extreme case a self-maintained thermo-nuclear explosion would be unlikely to be started by an atom bomb. It is probable, however, that if heavy water were incorporated in the bomb, with some of the energy liberated in the explosion being derived from deuteron reactions, more complete fission of the active heavy-element constituent would be ensured by the neutrons emitted by the reaction.

Catalogue of Laboratory Equipment

In the days before the War, the comprehensive catalogues of the laboratory furnishing firms were the 'bibles' of all those concerned with the ordering and purchasing of laboratory apparatus and instruments. The long years of abnormal circumstances and particularly of paper shortages have deprived laboratory workers of these ready and compact sources of information covering the whole range of scientific laboratory equipment. It is therefore heartening as a foretaste of more normal conditions that Messrs. Griffin and Tatlock, Ltd., have been able to issue a new and very substantial catalogue of scientific apparatus, and that the familiar, but out-of-date, pre-war publication of this firm, which for so long has been indicative of what might once have been obtained, can be replaced by this new list of what is now available. It is obvious from the contents of the catalogue that the scientific apparatus industry of Great Britain has not only completed the transition from war to peace manufacture, but has also expanded its range of products to cover gaps in its production which existed before the War; every article in this most comprehensive list of scientific apparatus is made either by the firm itself or by some other British manufacturer. The catalogue is an attractive publication, and in its arrangement due attention has evidently been paid to the convenience of the user. The catalogue is divided into thirteen sections, each dealing with the apparatus and instruments required for the teaching and experimental work of a particular subject in university and other educational laboratories. In addition, there are a list of chemicals and reagents and a very full index. One very useful aspect of the catalogue is the full description given of many of the items, together with articles on the methods and theory of use. Messrs. Griffin and Tatlock are to be congratulated on this praiseworthy effort.

Publication of Papers on Physics

Prof. E. N. da C. Andrade, in his presidential address to the Physical Society in 1945, referred to the "need of a medium for the publication of original papers on physical problems whose main interest was industrial and technical" (*Proc. Phys. Soc.*, 57, 21; 1945). To meet this need the Board of the Institute of Physics and the Council of the Physical Society have proposed the introduction of a new journal of applied physics, which, it is hoped, will commence early in 1948. A journal of about 400 pages a year, issued quarterly, is contemplated, devoted to applications of physics, containing papers on original work in technical physics, border-line papers on subjects which are not strictly 'fundamental' physics, reviews of recent advances, discussions, and, probably, editorials, notices of meetings and news items. A Joint Advisory Panel, on which every Group of the Society and all the Groups and local Branches of the Institute will be represented, is to be set up to work out the details. The rate of subscription to the new journal will, at first, be one guinea a year to members of the Society or Institute, and about 30*s.* to non-members.

In his address, Prof. Andrade pointed out also that the increased number of papers communicated to the Physical Society for publication would necessitate issuing two volumes a year of the *Proceedings* instead of the present one. The Council has accordingly announced that, from January 1948, the *Proceedings* will appear in two volumes a year, each consisting of six parts issued monthly, in order that the period between the communication and publication of papers may be reduced. In spite of the title *Proceedings*, a change of which was recently proposed but rejected by the members, papers are published in the Society's journal which are not necessarily a part of the proceedings of meetings. It is felt that, as many Continental physical journals ceased publication during the War and have not yet reappeared, Continental physicists may find a medium for the publication of their work in the Society's journal, now that more space and more rapid publication are assured.

Paper for Technical Journals

Mr. H. Wilson, president of the Board of Trade, replying to Mr. Erroll in the House of Commons on October 30, said that steps are being taken to ensure to journals devoted primarily to original research their full requirements of paper, and he hopes to exempt technical periodicals from the reduction which it is necessary to make in the paper available for periodicals generally.

Breeding of the Moustached Warbler in Britain

Conclusive evidence produced by R. A. Hinde and A. S. Thom (*British Birds*, 40, No. 4; April 1947) shows that the first recorded breeding of the moustached warbler (*Lusciniola melanopogon*) in the British Isles took place in Cambridgeshire in 1946. The evidence was compounded from observations made by a group of distinguished ornithologists, and the dark crown and superciliary stripe, as well as the cocking of the tail, leave no doubt that this Mediterranean bird, the nearest part of whose normal range is the south of France and whose sole previous claim to a place in the British list rested on a single occurrence, must now be added to the list of birds which have been known to breed in Britain.

Swiss Earthquakes during 1945

This annual seismological report of the Swiss observatories has been compiled by Dr. E. Wanner of Zurich. Seismographs are installed at the Swiss Observatories of Zurich, Chur, Neuchâtel, Basel and Brig, and during the year 85 near earthquakes and 189 strong distant earthquakes were registered. There were ten earth tremors with epicentres in Switzerland which were felt by people during the year. None of these had a greater intensity than V on the Rossi-Forel Scale, so that none reached destructive intensity. The greatest three tremors were (1) May 13 at Freiburg, (2) October 13 at Engadine and (3) November 10 at Wildhorn.

Science in the U.S.S.R.

A symposium on "Science and the Soviet State" in honour of the thirtieth anniversary of the U.S.S.R. is being organised by the Science Section of the Society for Cultural Relations with the U.S.S.R., 14 Kensington Square, London, W.8. The chairman of the meeting, which will be held at the Caxton Hall, London, S.W.1, on November 12, at 6.30 p.m., will be Sir Robert Watson-Watt, and speakers will include Prof. J. D. Bernal on "The Scientist as Citizen", Prof. V. Gordon Childe on "Archæology and the State", and Mr. Andrew Rothstein on "Science and Economic Planning". Tickets for the meeting (2*s.* 6*d.* each) can be obtained from the Society for Cultural Relations.

Medical Sub-section of the Library Association

The inaugural meeting of a new Medical Sub-section of the Library Association was held at Chaucer House on October 4. The following committee was appointed to manage the affairs of the group: C. C. Barnard, London School of Hygiene and Tropical Medicine (*chairman*); Miss E. Wigmore, Medical Research Council; W. A. Lee, Liverpool Medical Institution; W. R. Le Fanu, Royal College of Surgeons of England; T. J. Shields, British Medical Association; G. Wilson, Medical Library, University of Manchester; and W. J. Bishop, Wellcome Historical Medical Museum, 28 Portman Square, London, W.1 (*hon. secretary*).

Fractional Precipitation of Serum Proteins

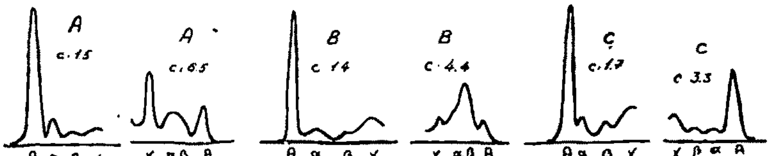
In a recent note[1], we described the purification of renin by means of a fractional precipitation with protein-precipitating agents (sulphosalicylic acid and tungstic acid). In order to test the adaptability of this method, we have investigated the fractional precipitation of blood serum using electrophoresis (Tiselius) for analysing the composition of the products isolated. The most important of the results so far obtained is that it is possible, if we choose the right conditions and suitable precipitating agents, to perform the fractionation with a high degree of selectivity.

(*A*) To 40 ml. ox serum diluted with 40 ml. phosphate buffer (*p*H 7·6) was added 1·22 ml. *M* sodium tungstate and then precipitated with *N* hydrochloric acid until it reached *p*H 6·8. The accompanying electrophoresis curves show a large amount of γ-globulin in the precipitate, considerably less of a component containing α- and β-globulin and only small amounts of albumin. In the filtrate large amounts of albumin, some α-globulin but almost no β- and γ-globulin remained.

(*B*) To 19 ml. ox serum diluted with 19 ml. phosphate buffer (*p*H 7·6) was added 10 per cent sulphosalicylic acid until it reached *p*H 4·0. In the filtrate large amounts of albumin, some γ-globulin but almost no α- and β-globulin remained. The precipitate contained a small amount of albumin, a very large amount of α-globulin, a considerable amount of β-globulin but almost no γ-globulin.

(*C*) To 20 ml. ox serum diluted with 20 ml. phosphate buffer (*p*H 7·6) was added 0·7 ml. *M* uranyl nitrate and solid bicarbonate until the precipitate was again dissolved (about *p*H 8); then *N* hydrochloric acid until it reaches *p*H 6·3. The compositions of filtrate and precipitate are almost identical and correspond to the composition of the original ox serum.

These three examples show the very conspicuous dissimilarity in the products obtained when different conditions and precipitating agents are used. While the uranyl nitrate evidently precipitates the different components to almost the same degree, tungstic acid precipitates chiefly the γ-globulin, and sulphosalicylic acid mainly α- and β-globulin. The only case known to us in which a similar procedure has been used previously is the precipitation of inert proteins from mare serum gonadotrophin by means of sulphosalicylic acid[2] or metaphosphoric acid[3]; but here the bulk of proteins is removed and only a very small amount, containing the active substance, remains in the solution.



Fractional precipitation of ox serum with (*A*) tungstic acid, (*B*) sulphosalicylic acid, and (*C*) uranyl nitrate. *c* denotes the concentration of the solution investigated in relation to the original serum. Left-hand members of pairs, filtrates; right-hand members of pairs, precipitates

By changing the conditions of precipitation (*p*H, salt concentration, dilution, temperature) and the nature of the agents used for formation of the slightly soluble protein compounds, it is possible to modify this method between much wider limits than the methods usually employed in protein fractionation.

This work was aided by a grant from the Teknisk-kemisk Fond; it is being continued and the results will be published elsewhere.

Constitution of Salmine

It has recently been suggested[1] that salmine may be a cyclic peptide because it does not appear to contain any free carboxyl groups when these are estimated by the methods of Fraenkel-Conrat[2] and Herriot *et al.*[3]. This suggestion is in direct contrast to the findings obtained in the present work, to be fully reported elsewhere. A complete amino-acid analysis of salmine sulphate suggests a molecular weight of 8,000 and a peptide chain of 58 residues:

Amino-acid	Amino-acid N as % protein	Amino-acid/100 gm. protamine	Min. mol. wt.	No. of residues	Calc. mol. wt.
Arginine	89·0	85·2	204	40	8160
Isoleucine	0·56	1·61	8140	1	8140
Valine	1·20	3·1	3770	2	7540
Proline	2·29	5·8	1980	4	7920
Glycine	1·78	2·94	2550	3	7650
Alanine	0·56	1·10	8100	1	8100
Serine	3·94	9·1	1152	7	8050
	99·33	108·85		58	7930

The protamine sulphate contains 19·85 per cent H_2SO_4 (40 equivalents per molecule), being sufficient to combine with all the arginine residues in the molecule. The amino-acids reported by Block and Bolling[4] have been confirmed, by isolation as acetyl derivatives; in addition, glycine has been shown to be present in the protamine.

End group analysis by the method of Sanger[5] (Porter, private communication) has shown that proline occupies the terminal imino position. There is no reason to suppose that the procedure of Sanger has resulted in the opening of a cyclic peptide, since a similar procedure carried out on gramicidin-*S*[6] showed that this material was indeed a cyclic peptide.

It seems reasonable to assume that salmine is a normal peptide, and that the methods used by Fraenkel-Conrat and Olcott[1] are not applicable to a protein with such singular properties as salmine.

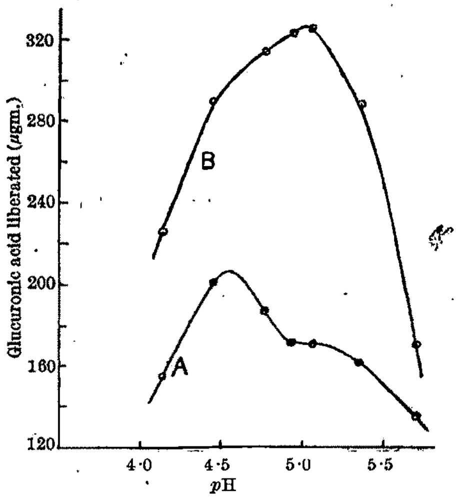
β-Glucuronidase Activity of Ox Spleen

β-GLUCURONIDASE was first prepared from ox kidney by Masamune[1] and later from ox spleen by Fishman[2,3] and Graham[4]. Each of these workers, using *l*-menthylglucuronide as assay material, indicated that only one glucuronidase was present. Talalay, Fishman and Huggins[5], using phenolphthalein-glucuronide as substrate, came to a similar conclusion.

A re-investigation of the method of preparation and purification of β-glucuronidase from ox spleen revealed that the problem was not so simple as previously indicated. A crude glucuronidase extract from ox spleen was analysed by the 'variable solvent solubility' test as defined by Falconer and Taylor[6] at *p*H 5·0, using ammonium sulphate as precipitant. The results of this test indicated that two protein fractions having glucuronidase activity existed in this crude extract. Similar results were obtained in a test carried out at *p*H 7·0. At *p*H 6·0, however, only one fraction was apparent.

Using the data obtained in these experiments, the crude glucuronidase extracts were fractionated with ammonium sulphate at *p*H 5·0 and the two fractions separated, which on further purification gave the *p*H activity curves shown in the accompanying graph. *l*-Menthylglucuronide and acetate buffers were used in these experiments.



*p*H ACTIVITY CURVES OF THE ENZYMES OBTAINED BY FRACTIONATION, USING DATA OBTAINED IN SOLUBILITY TESTS. ASSAYS USING 0·1 *M* ACETATE BUFFERS AND 0·01 *M* *l*-MENTHYLGLUCURONIDE

A, fraction precipitated between 1·26 and 1·54 *M* $(NH_4)_2SO_4$
B, ,, ,, ,, 1·54 and 1·76 *M* $(NH_4)_2SO_4$

Fishman[2], in his experiments, fractionated the ox spleen extracts between 37 and 50 per cent saturation ammonium sulphate, and Graham[4] used the limits 36 and 46 per cent saturation. From the data obtained in the solubility tests, it is obvious that these two workers eliminated the glucuronidase having an optimum *p*H of 4·5 for the hydrolysis of *l*-menthylglucuronide, since the limits of precipitation with ammonium sulphate are 31·5–38·5 per cent saturation for this enzyme, and 38·5–44 per cent saturation for the enzyme having an optimum *p*H at 5·0.

Preliminary results appear to indicate that the relative amounts of these two enzymes vary in different extracts, rendering inaccurate, therefore, glucuronidase assays using only one *p*H value.

Full details of these experiments will be published later in the *Biochemical Journal*.

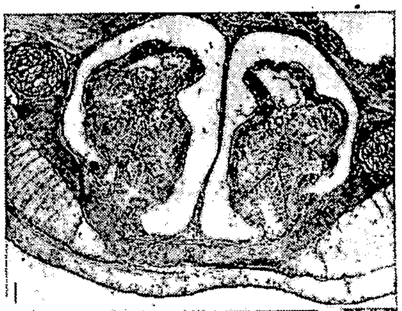
Effect of Thiourea on the Endostyle of Ammocœtes

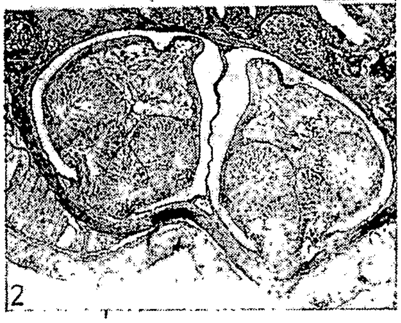
RESULTS of recent investigations[1–3] have directed attention to a group of drugs which produce hypothyroidism and hyperplasia of the thyroid gland in rats, mice and dogs. These drugs include sulphonamides and various derivatives of thiourea and of thiouracil. Inhibition of amphibian development by thiourea[4] and by thiouracil[5] has been reported.

Like the amphibians, the lamprey (*Petromyzon fluviatilis*) undergoes metamorphosis; on account of this and because the exact function of the endostyle is still a matter for conjecture, a preliminary experiment was carried out to find the effect, if any, of thiourea on the endostyle of the ammocœte.

Four ammocœtes were kept in a solution of 0·033 per cent thiourea in tap water, with mud and waterweed, which was aerated by means of a pump. The solution was changed every day. The animals were killed on the eleventh day. Four other ammocœtes were kept as controls under similar conditions in tap water and killed on the eleventh day. They were all fixed in Bouin's fluid and the sections were stained with hæmatoxylin and orange G.

As a result it was found that in the endostylar glands of the controls there were many vacuoles and the nuclei of the cells were unevenly distributed (Fig. 1); whereas the endostylar glands of the





thiourea-treated ammocœtes showed an absence of large vacuoles and the nuclei were basally placed (Fig. 2).

Stabilization of Penicillin-Salt Solutions with Sodium Citrate

In a recent paper[1], I described the stabilizing effect of sodium citrate dissolved in physiological salt solution on the rate of destruction of sodium penicillin solutions by heat. Only very dilute concentrations of sodium penicillin (1–5 units per ml.) were used.

The present communication deals with the effect obtained with higher concentrations; 100, 1,000 and 3,000 u./ml. were tested and the optimal molar concentration of sodium citrate assessed.

Method. The agar-cup method as described in my previous paper was used. The average of at least three assays was compared with the standard curve constructed daily.

Results. (1). Solutions containing 100 and 1,000 u./ml. sodium penicillin (T.R.C. tabl. 392) were made up with sodium citrate solutions ranging from $M/20$ to $M/600$. The optimal effect was obtained with $M/400$ at pH 5·6 and solutions (*a*) in $M/400$ sodium citrate, (*b*) in distilled water adjusted to the same pH with phosphate, and (*c*) in one test with distilled water pH 4, were heated at 100° C. The results were as follows:

	Percentage of penicillin remaining				
at 100° C.	100 u./ml.			1,000 u./ml.	
after	(*a*)	(*b*)	(*c*)	(*a*)	(*b*)
15 min.	75	75		100	100
30 ,,	60	70	37	80	80
45 ,,	50	35		80	56
60 ,,	25	12·5		80	48

It will be noted that the rate of destruction of sodium penicillin by heat was about the same in (*a*) and (*b*) up to 30 min., but higher in (*c*). After 45 and 60 min. the sodium citrate effect exceeds that of buffered distilled water.

(2) 3,000 u./ml. sodium penicillin T.R.C. 392 dissolved (*a*) in $M/1,000$ citrate solution pH 6·4 and (*b*) in distilled water adjusted to pH 6·3 with phosphate gave the following results after boiling:

	Percentage remaining	
min.	(*a*)	(*b*)
50	65	50
75	48	40
150	17	10

(3) *Stabilization at room temperature.* Ampoules were filled with penicillin salt solutions, then kept at 100° C. for 15 minutes and afterwards at room temperature. The samples remained sterile as proved by several tests for sterility. The solutions contained: (*a*) 10,000 u./ml. sodium penicillin (The Distillers Co., Ltd., Liverpool) (915 units per mgm.) in $M/500$ citrate solution, (*b*) the same in $M/1,000$ citrate solution:

Percentage of penicillin remaining		
after days	(*a*)	(*b*)
21	80	80
28	59	63
35	41	48

A solution containing 1,000 u./ml. sodium penicillin T.R.C. 330 dissolved in distilled water lost 82 per cent of its potency after twenty-five days.

Microbiological Oxidation of Cholesterol with *Azotobacter*

L. Mamoli and A. Vercellone[1] were the first to work with the microbiological oxidation of sterols. They carried out investigations principally in a series of sex hormones, and with the aid of Coryne-bacteria, cultivated together with yeast, oxidized steroid alcohols to ketones. Recently, G. E. Turfitt[2] found identical results with certain species of *Proactinomyces*.

At the beginning of our work we also used *Proactinomyces*; but we found that the species we isolated were capable only to a small degree of transforming steroid alcohols to ketones (in our experiments, principally cholesterol). We carried out our further investigations with a species of *Azotobacter* and observed the following results:

(1) The transformation of cholesterol to cholestenone was much more successful with *Azotobacter* than with our species of *Proactinomyces*.

(2) Besides the dehydration of the oxy-group, the *Azotobacter* also dehydrates within the sterol ring; thus from the reaction product we succeeded in isolating 7-dehydrocholesterol.

(3) Parallel to dehydration, a stronger oxidation of the cholesterol also took place, as after the process methylheptanone was also formed, from which the splitting off the side-chain could follow.

Our experiments were carried out in the following way. Cholesterol was dispersed in a rich synthetic culture medium of saccharose. The mixture was sterilized and added to the *Azotobacter* culture. A lively fermentation began, which lasted for three–four days, then gradually diminished. On the fourteenth day, after weak alkali hydrolysis, it was extracted with benzene. From the residue of the extract unchanged cholesterol was regained, then the methylheptanone was obtained by vapour distillation. The cholestenone was isolated through its semi-carbazone, and the 7-dehydrocholesterol by chromatographic adsorption.

Our experiments also support the hypothesis[3] according to which 7-dehydrocholesterol in the organism results from an enzymatic action on cholesterol.

The determination of the *Azotobacter* species, as well as the identification of the product formed by the splitting off of the side-chain, are in hand. The experiments also aim at ascertaining the effect the *Azotobacter* species exercises on certain substances of the sterol series.

A Modified Microbiological Assay Procedure

At a joint meeting of the Biochemical Society and the Society for General Microbiology, the principles underlying microbiological assay were discussed in some detail[1]. The advantages of measuring bacteriological growth directly, thus avoiding the need to pass the lag period before making indirect measurements of growth, such as acidimetry, are offset by the greater complexity of apparatus and technique needed in the more direct ones, such as turbidimetry.

During the discussion at the meeting, I suggested that it might be possible to make the best of both worlds by applying in reverse to the assay of vitamins and amino-acids the principles now very generally adopted for the assay of penicillin and other antibiotics. In other words, the medium would be devoid of the vitamin to be estimated and would be inoculated with the chosen strain of organism, graded amounts of the vitamin being then pipetted into suitably formed cups, using the ordinary Petri dish and agar medium as in the Heatley test and its various modifications. This should result in a circular area of growth round the cup, that is, in a 'zone of exhibition'.

It was not possible to investigate this matter for some time after the meeting mentioned; but Dr. W. F. J. Cuthbertson in these Laboratories has now been able to do so. We find that the zones are, indeed, graded to dose, being over a fairly wide range proportional in diameter to the logarithm of the amount of the test vitamin in the cup. The method seems to work not only for riboflavine and aneurine, on two different media, but also for several other vitamins of the *B* group.

Among the several advantages of this method, which may be of wide application, there are two outstanding ones. In the first place, it puts at the disposal of the microbiological assayist a far wider range of organisms than hitherto, for he is no longer restricted to those that produce acid. This may mean, in effect, that he can bring into use for analytical purposes some of the less-exacting organisms that are known to require only one or two organic nutrients, apart from a source of carbohydrate with the usual mineral salts. The second outstanding advantage is speed, for it has been found not merely possible but desirable to use media and techniques giving maximum growth in less than 24 hours. The Petri dish procedure, furthermore, besides making replication easy, lends itself very well to tests of factorial design with subsequent analysis of variance in their statistical treatment. The chief disadvantage encountered is that, in comparison with the acidimetric technique in test tubes, considerably higher concentrations must be used, and the method as at present carried out cannot be applied to, for example, the estimation of riboflavine in flour and other wheat products.

Further work on the test is in hand, and it is hoped to publish a more detailed account at a later date.

Escape of Thoron from Thorium X Salts

THE absorption method devised by several authors[1,2,3] for obtaining the relative amounts of radium, mesothorium and radiothorium in the mixed salts of these elements in terms of their gamma-ray equivalent has been used for some sixteen sources of this kind destined for a radium mass-unit.

In fifteen of these sources the salts, forming a sphere 5 mm. in diameter and enclosed in a steel tube with walls 1 mm. thick (Fig. 1), emit gamma rays equivalent to 180 mgm. of radium, from which about 34 per cent belong effectively to the gamma rays of radium B + C, 33 per cent to mesothorium 2 and 33 per cent to thorium C + C″.

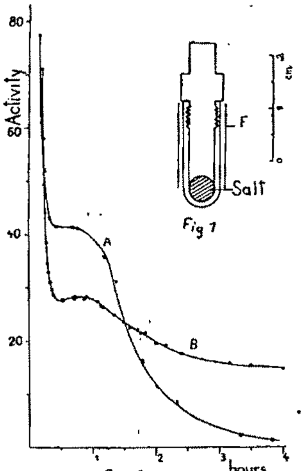

Fig 1

Fig 2

As several of these tubes leaked considerably after they had been sealed, an attempt was made to compare the amount of the escaping radon to that of the thoron by means of their active deposits. We hoped to obtain in this way some information concerning the relation between the parent elements of these two emanations.

In the first experiment the leaky container was exposed for 1 hour in an air-tight vessel (volume 1·5 l.) filled with air at normal pressure. After exposure, the air of the vessel was passed into an evacuated ionization chamber, measured with a bifilar electrometer, and after a total time of 5 min. in the chamber removed and replaced by inactive dry air. The activity of the air amounted to several microcuries.

The residual activity of the chamber after the active air has been removed gave a typical curve (*A*, Fig. 2) of the radon-active deposit of rapid change, with no trace of the thoron-active deposit.

This experiment has been repeated in a different manner. When filling the ionization chamber the air current was passed directly upon the tube with radioactive salts enclosed in a glass tube of slightly larger diameter. With other conditions identical with those of the previous experiments, the residual activity of the ionization chamber (curve *B*, Fig. 2) gave after four hours the well-known plateau of the active deposit of thoron.

In order to find if the thoron is able under normal conditions to escape from the tube at all, a tin-foil (*F*, Fig. 1) was wrapped directly on the tube and left there for 5 min. The activity of the tube was then measured by means of alpha rays. A decay curve of exactly the same shape as curve *A* was obtained, which is decisive proof that no thoron whatever escapes from the tube containing radioactive salts.

Even with regard to the short half-life period of thoron (54·5 sec.) these results are surprising. They show (1) there is no leakage of thoron from the unsealed radiothorium containers when exposed in the free air; (2) to remove the thoron from the radiumthorium salts a notable difference between the pressure of the surrounding air and of the air enclosed with the salts is necessary.

In the light of these results, the assertions of several workers[4] that there exist atoms of thoron-active deposit in the atmosphere, based only on the measurements of the activity of a negatively charged wire exposed in the free air, need revision.

Crystal Structure of Hydroxylammonium Chloride and Bromide

HYDROXYLAMMONIUM chloride, NH_3OHCl, and hydroxylammonium bromide, NH_3OHBr, are isomorphous and belong to the space group $C_{2h}^5 - P2_1/c$. The unit dimensions are

NH_3OHCl $a = 6{\cdot}94$ kX., $b = 5{\cdot}94$ kX., $c = 7{\cdot}68$ kX., $\beta = 120{\cdot}8°$
NH_3OHBr $a = 7{\cdot}28$ kX., $b = 6{\cdot}12$ kX., $c = 8{\cdot}03$ kX., $\beta = 120{\cdot}8°$

The unit cell contains 4 NH_3OHX.

The structure was determined by means of one-, two-, and three-dimensional Fourier syntheses. In this way it was possible to determine the parameters with great accuracy, but the electron density data were not sufficient to settle the question as to which peaks corresponded to nitrogen and which to oxygen. The neighbourhood of these light atoms and the distribution of the charges support the following choice, exemplified by the chloride:

4 N in 4(*e*) : $x_1 = 0{\cdot}283$, $y_1 = 0{\cdot}664$, $z_1 = 0{\cdot}222$
4 O in 4(*e*) : $x_2 = 0{\cdot}253$, $y_2 = 0{\cdot}870$, $z_2 = 0{\cdot}106$
4 Cl^- in 4(*e*) : $x_3 = 0{\cdot}233$, $y_3 = 0{\cdot}190$, $z_3 = 0{\cdot}395$

Two NH_3OH^+ groups and two Cl^- are thus situated in the immediate vicinity of each of the planes ($\frac{1}{4}$ y z) and ($\frac{3}{4}$ y z). This layer structure explains the pronounced cleavage parallel to (100). The distance N—O within the same NH_3OH^+ group is 1·45 kX., which is in rather good accordance with the sum of the covalent radii of N and O.

The closest Cl^- neighbours of a nitrogen atom are at distances of 3·16, 3·21, 3·22 and 3·25 kX. This is comparable with the closest approach between Cl^- and the N atom of the $-NH_3^+$ group in geranylamine hydrochloride[1] (3·17–3·24 kX.), methylammonium chloride[2] (3·18 kX.), and hydrazinium dichloride[3] (3·10 kX.). The distribution of these closest four Cl^- neighbours around the N atom is similar to the corresponding distribution in geranylamine hydrochloride[1] and hydrazinium dichloride[3].

The oxygen atoms have the closest two Cl^- neighbours at distances of 2·98 and 3·04 kX. The closest Cl^-—Cl^- approach is 3·91 kX.

A more detailed report will follow elsewhere.

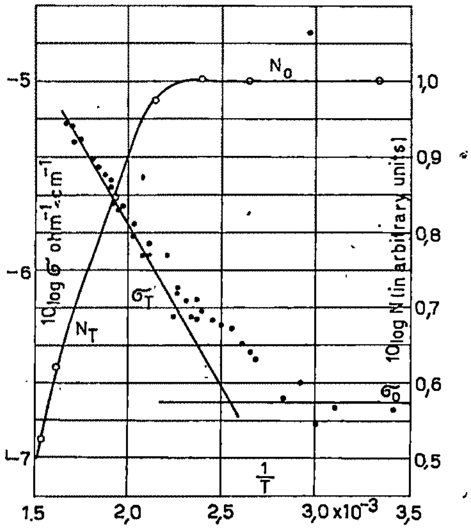
Dielectric Losses and Fluorescence of Zinc Silicate

WHILE investigating a manganese-activated zinc silicate, we have found that the temperature-dependence of the dielectric losses and that of the fluorescence (2537 A. excitation) show an intricate connexion. In the accompanying graph there is plotted the logarithm of the total number of light quanta emitted (*N*) and the logarithm of the electrical conductivity (σ) obtained by measuring the dielectric losses at 20 Mc. (without ultra-violet irradiation) as a function of the reciprocal absolute temperature.



At lower temperatures the fluorescence and the conductivity can be considered as constant (N_0 and σ_0 respectively). At higher temperatures, however, the fluorescence shows a sudden decrease (N_T), while the conductivity (σ_T) increases, giving a straight line in our co-ordinate system.

$$\log \sigma_T = \log A - B/2kT. \qquad (1)$$

In eq. (1), *A* is practically constant over the temperature-range of our investigations, though theoretically it should be slightly temperature-dependent; *B* is an activation energy, giving the distance between electron donator and acceptor zones; *k* is Boltzmann's constant; and *T* denotes the absolute temperature. Below a critical temperature (approx. 445° K.) the observed conductivity values indicate a deviation from the law mentioned above, showing a gradual transition into the temperature-independent conductivity (σ_0). The resulting conductivity is, therefore,

$$\sigma \doteq \sigma_0 + \sigma_T = \sigma_0 + A \exp. (- B/2kT). \qquad (2)$$

The numerical values for our zinc silicate sample are: $\sigma_0 = 0{\cdot}2 \times 10^{-6}$ ohm^{-1} cm.$^{-1}$, $A = 5{\cdot}4 \times 10^{-3}$ ohm^{-1} cm.$^{-1}$ and $B = 0{\cdot}7$ eV.

From these observations, we deduce that the ultimate absorption of the ultra-violet radiation takes place in centres, the number of which is in close relation to the electrical conductivity. Assuming that at temperature T the mobility of the carriers of electricity is the same for σ_0 and σ_T, the total number of carriers is $c_1(\sigma_0 + \sigma_T)$, whereas the number of absorption processes is $c_2(\sigma_0 + \alpha\sigma_T)$, where c_1 and c_2 are constants and α is the absorption coefficient for the σ_T centres, taking the absorption coefficient for σ_0 centres as unity.

The ultra-violet quanta absorbed by σ_0 centres give rise to the emission of the same number of fluorescent light quanta, whereas the absorption by a σ_T centre is non-luminescent. Denoting by N_T the total number of quanta emitted at temperature T, and by N_0 the same at a low temperature, where $\sigma_T \ll \sigma_0$, the temperature dependence of N_T can be expressed by

$$N_T = N_0 \frac{c_2\sigma_0}{c_2(\sigma_0 + \alpha\sigma_T)}. \qquad (3)$$

Our measurements for the zinc silicate sample examined led to a value $\alpha = 0{\cdot}036$. With the measured values of σ_0 and σ_T we calculated N_T/N_0 and compared it with the measured luminescence.

	T° K.	300	418	518	623	648
$10^6\sigma_T$	obs.	0·022	0·35	2·2	8·3	10·7
N_T/N_0	calc.	0·996	0·94	0·72	0·40	0·34
	obs.	1·00	1·00	0·71	0·42	0·34

The same simple basic connexion was found to be valid for other phosphors too.

We express our thanks here to Prof. Z. Bay, director of the laboratory, for his interest, and to Prof. P. Gombás for suggestions and critical discussions.

F_2 Ionization and Geomagnetic Latitudes

WHILE studying the relation between the anomalous distribution of F_2 ionization in the ionosphere and the geomagnetic co-ordinates of various observatories, we found that Sir Edward Appleton had already published his results[1] (that issue of *Nature* was not available to us until two months ago owing to post-war difficulties), showing clearly the symmetry of F_2 critical frequencies with respect to the dip angles south and north of the magnetic equator. Later, Prof. S. K. Mitra gave reasons[2] explaining the geomagnetic control of F_2 ionization, and found that the location of maximum critical frequencies obtained from his calculation agrees very well with that shown by Appleton's result. In our work, the critical frequencies are plotted against the geomagnetic latitudes—Figs. 1 and 2 for March and September 1946. Compared with Figs. 3 and 4, where the critical frequencies are plotted against dip angles they show a similar appearance of symmetry. I feel, however, that the dip angles as measured near the surface of the earth, inevitably influenced by local factors, may not represent at all well the geomagnetic effect in a region far above the earth such as the F_2 region in the ionosphere.

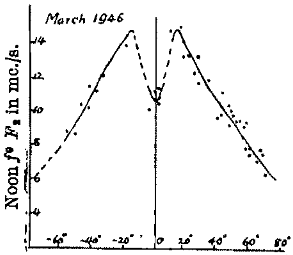

Fig. 1

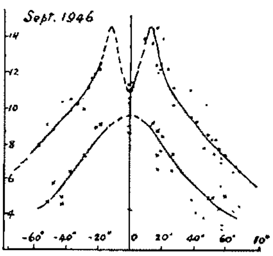

Fig. 2

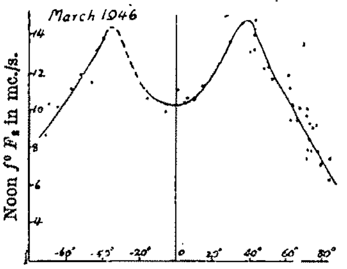

Fig. 3

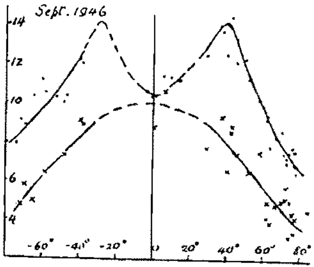

Fig. 4

With reference to the above graphs, the following points are of interest:

(1) The two sets of curves for noon values of $f^0 F_2$, one for March and the other for September, are quite similar. Those plotted with geomagnetic latitudes as abscissæ both show maxima at approximately 14° N. and S.

(2) The curves plotted with dip angles[3] as abscissæ both have maxima around 38° N. and S. These seem to be different from Sir Edward Appleton's figure, in which maxima appear at 28° N. and S., as pointed out by Prof. Mitra in his communication.

(3) Midnight critical frequencies for September 1946 are also plotted in Figs. 2 and 4. There is no drop in value for stations near the magnetic equator. The distribution of points around the smoothed curves are much wider than for noon critical frequencies. However, they still show symmetry with respect to the geomagnetic constants (magnetic latitudes and dip angles) rather than geographic latitudes.

(4) It seems that the drop in ionization near the magnetic equator for the noon curves cannot be entirely attributed to the drift of ions caused by the earth's magnetic field. Since equatorial March or September corresponds to summer in temperate zones, the heating and expansion effect may also account for the drop in ion density. In the equatorial region, noon values are sometimes less than midnight values, as may be seen in the above graphs.

I wish to thank Messrs. S. Wang and W. Chow for their help in the preparation of this letter, and Dr. P. C. T. Kwei for his criticism. The world ionospheric data which have been freely used in this work are supplied by the Central Radio Propagation Laboratory of the National Bureau of Standards, Washington, which subsidizes the Ionosphere Laboratory here in co-operation with the National Wuhan University.

[3] Obtained from Fig. 8, p. 12, "Terrestrial Magnetism and Electricity", edited by J. A. Fleming.

I AGREE with Prof. Liang about the desirability of plotting F_2-layer critical frequencies with magnetic latitude rather than with magnetic dip. In an article in *Science*, p. 17, July 4, 1947, I have given such a plot, which, for noon values of equinox critical frequency, shows two sharp maxima at ± 18° magnetic latitude. The high midnight values of F_2-layer critical frequency at stations on the geomagnetic equator are also attributed to the low electron recombination which is associated with the marked bifurcation of the F-layer into the F_1 and F_2 strata.

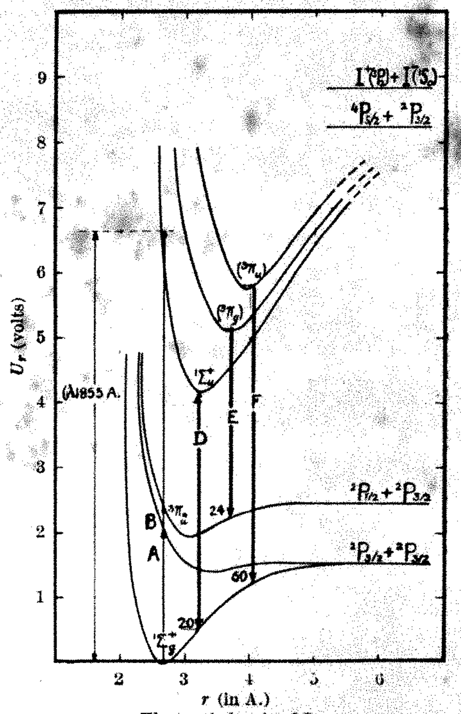
Emission Spectrum of Iodine Molecules in the Presence of an Inert Gas

THE emission spectrum of iodine (I_2) between 5000 and 2500 A. consists of a large number of diffuse bands (McLennan bands) and, especially in the presence of *small* amounts of an inert gas, of some apparently structureless continua[1] at 4800, 4300 and 3420 A. However, as has been shown, particularly by Elliott[2], the spectrum has quite a different appearance if excited in fluorescence by the Al spark lines at 1855–1863 A. in the presence of *large* amounts of nitrogen. The McLennan bands disappear almost entirely, the continua change into well-developed band systems at 4630–4440, 4321–4041(E) and 3450–3040 A.(D), and another well-developed band system appears at 2730–2520 A.(F). From a vibrational analysis of system D, Elliott was able to confirm an earlier interpretation of this system as an electronic transition from an upper state ${}^1\Sigma_u^+$ to the ground state ${}^1\Sigma_g^+$ of I_2 (with vibrational quantum numbers $v'' = 13$–29). He also set up a formula for system F, but his v''-assignment is uncertain, and indeed entirely incorrect according to our analysis. He was unable to interpret the other two systems.

We succeeded in obtaining the emission spectrum of iodine vapour in the presence of several hundred millimetres of argon by a high-frequency discharge. The spectrum was photographed with prism spectrographs of high dispersion and proved to be very similar to the fluorescence spectrum of Elliott. The main differences consist in the absence of the bands (degraded towards the violet) at 4630–4440 A., which, therefore, might belong to the molecule IN, and the appearance of three small continua or band systems at 2880, 2820 and 2770 A. not present in Elliott's fluorescence spectrum (but present in the spectrum excited by active nitrogen[2]). Our present investigation is concerned only with the well-developed band systems F and E. The vibration analysis of these systems strongly suggests the interpretation sketched in the accompanying figure. This assignment of electronic levels is supported by energy considerations based on the fact that the systems considered may be obtained in fluorescence by light of λ 1855 A.



Electronic levels of I_2

The observed band heads, with very few exceptions, are represented, with an average error of about ± 2 cm.$^{-1}$, by the following formulæ :

System F : 2720–2533 A. bands degraded towards the red

$$v = 46440{\cdot}7 + (96{\cdot}21\, v' - 0{\cdot}49\, v'^2) - (213{\cdot}77\, v'' - 0{\cdot}599_5\, v''^2 - 0{\cdot}00367\, v''^3)$$

with $v' = 0$–5, $v'' = 40$–62, intensity maximum at $\sim v', v'' = 3,60$.

System E : 4327–4039 A. bands degraded towards the red

$$v = 25757{\cdot}2 + (101{\cdot}88\, v' - 0{\cdot}34\, v'^2) - (126{\cdot}59\, v'' - 0{\cdot}755\, v''^2 - 0{\cdot}0033\, v''^3)$$

with $v' = 0$–8, $v'' = 13$–32, intensity maximum at $\sim v', v'' = 1,24$.

Our formula for the ground-state of I_2 involved in system F is valid for high values of v'' only (say, $v'' > 30$) and converges, as expected, more strongly than the formula $\nu_{(v'')} = 213{\cdot}76\ v'' - 0{\cdot}596\ v''^2 - 0{\cdot}0021\ v''^3$ given by Loomis[3], following Mecke, for small values of v'' (0–20). The formula used for the lower state of system E is the one given by Loomis for the upper state ${}^3\Pi_0$ ($= 0_u^+$) of the visible bands of I_2. The frequency difference of 5085 cm.$^{-1}$ between the upper electronic states of systems E and F suggests the tentative identification of these states with the terms ${}^3\Pi_g$ and ${}^3\Pi_u$ discussed by Mulliken[4].

All three band systems D, E and F are degraded toward the red and have their intensity maxima near the long wave-length end. This situation usually occurs if the atomic distance r' of the upper state is much larger than the distance r'' of the lower state, that is, if the upper potential curve has ionic character as discussed by Mulliken[4]. These states do not necessarily dissociate into the ions $I^+ + I^-$ but more probably into the lower lying state $I({}^4P_{5/2}) + I({}^2P_{3/2})$. It is of interest that ion-like spectra of this type occur also for the molecules HgX, CdX and ZnX [5], where X = Cl, Br, I.

A more detailed report is to appear in the *Helv. Phys. Acta*.

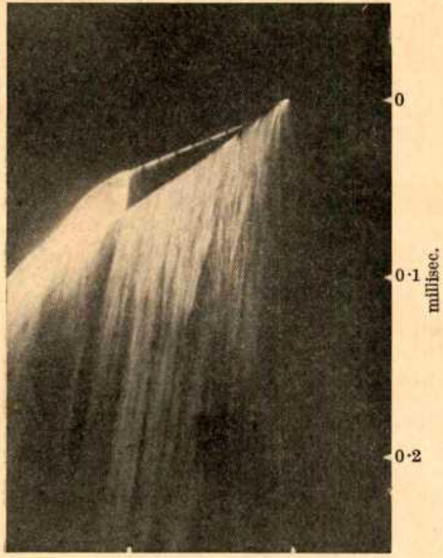
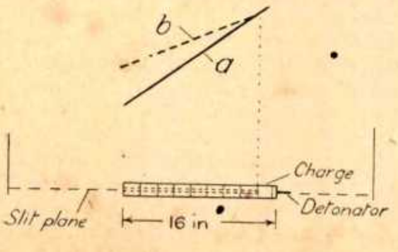
Velocity of Detonation of a Tubular Charge of Explosive

DETERMINATIONS of the velocity of detonation of unconfined columns of pressed tetryl pellets, made by me in these laboratories in 1941 by means of the Buxton rotating-mirror camera[1], showed that the velocity was higher by several hundreds of metres per second when there was a continuous cylindrical cavity in the column. For example, whereas the velocity of detonation in a cylinder of tetryl, 7/8 in. in diameter and of density 1·44, was 6,875 m./sec., the velocity in a cylinder of the same diameter but containing an axial cavity $\frac{1}{4}$ in. in diameter was 7,780 m./sec. Later experiments confirming and extending this result were made here by Dr. W. B. Cybulski with the same camera, after he had introduced modifications which considerably improved its accuracy.





The photographic record reproduced herewith was obtained by Cybulski with a tubular charge formed with pellets of an explosive, translucent when cast (40 : 60-tetryl/trinitrotoluene, density 1·62); the column was 16 in. long, $1\frac{1}{4}$ in. in diameter and contained an open cavity 14 in. long and 0·35 in. in diameter. Initiation was at the closed end. The trace depicted by line *a* of the explanatory diagram is formed by the detonation wave in the wall of the tube, and its slope corresponds with a speed of 7,380 m./sec. (the mean of six determinations having a range of 80 m./sec.). This is 255 m./sec. faster than the velocity of detonation, 7,125 m./sec., in a similar solid cylinder. With a narrower cavity, 0·25 in. in diameter, the speed in the wall rises to 7,410 m./sec., an increase over the normal rate of nearly 300 m./sec. The increase becomes smaller with wider cavities; for example, when the diameter is 0·64 in. the speed in the wall is 7,220 m./sec., an increase of only 95 m./sec. above the normal speed. The trace corresponding with line *b* of the diagram is of a luminous effect within the cavity and visible through the translucent explosive; it moves in advance of the detonation wave in the wall and is no doubt a manifestation of the well-known Munroe effect[2]. Within the cavity the speed is no less than 12,500 m./sec., and beyond the end of the column the effect is recorded as a flame of intense luminosity and long duration; for a short distance its speed is appreciably higher even than within the cavity.

Determinations of the velocity of detonation in cylinders of different diameters show that the value 7,125 m./sec. in this explosive is its limiting velocity, or the 'maximum possible velocity' of Berthelot. It is found that, when the cavity is filled with inert material such as 'Plasticine', the rate in the wall is the same as that in a solid charge; thus a higher value obtained experimentally with a hollow charge is abnormal in that it is a result of events within the cavity. That the passage of the luminous effect therein does not cause a forward motion of the tube, producing only an apparent increase in the velocity of detonation, has been proved by first superposing on the film a shadow photograph of the undetonated charge. At least two other explanations remain: that the passage of the internal effect is responsible either for immediate physico-chemical changes of the explosive in the wall, or for a modification in the form of the detonation wave therein.

The experimental work was carried out for the Ministry of Supply, and thanks are due to the Chief Scientist for permission to publish this note.

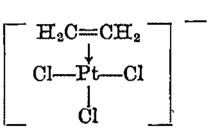
Co-ordination Complexes Containing Olefines

THE concept of the 'co-ordinate link' type of bond formed by donation of lone pair electrons has recently been generalized by Walsh[1] to include also donation by bonding electrons. A similar idea has been independently put forward by Dewar[2] to explain certain intramolecular rearrangements. This new idea that donation by bonding electrons may occur, thus conferring donor properties on the olefinic linkage, is attractive from the purely chemical point of view. In addition to the examples already mentioned by Walsh, additional evidence in support of this concept is to be derived from a consideration of the ability of olefinic compounds to enter into complex formation with metallic salts. This ability has been known since Zeise[3] described the compound $K[PtCl_3.C_2H_4]H_2O$, and it has been found to be widely distributed among the metals, although most strongly exhibited by platinum (*vide* Anderson[4]), in which it has been shown that the ethylenic linkage is functioning as a specific co-ordinating group for platinum. Manchot and Brandt[5] have found that ethylene forms a co-ordinate complex with cuprous chloride analogous to that formed by carbon monoxide; furthermore, Manchot[6] has shown that blood absorbs ethylene, giving rise to a complex similar to, but more easily dissociable than, oxy- and carboxy-hæmoglobin.

In all these co-ordination compounds with metallic salts there is evidence that ethylene plays a part analogous to that of carbon monoxide and ammonia in similar complexes; on chemical grounds there is no intrinsic difference between the co-ordination complexes containing ethylene and those containing either carbon monoxide or ammonia, and they differ merely in their relative degrees of stability. The complexes containing olefines are more easily dissociable, from which it may be inferred that the strength of the olefine → Pt bond is less than that of either the $CO \rightarrow Pt$ or the $H_3N \rightarrow Pt$ bonds. The exact nature of the bond uniting the olefinic molecule to the metallic atom has always remained rather obscure. As pointed out by Anderson (*loc. cit.*), the suggestion that a lone pair may be produced in the olefinic molecule by an electromeric change $R - CH = CH - R' \rightarrow R - \overset{+}{C}H - \overset{-}{C}H - R'$ (that is, derived from an excited state of the olefinic linkage) is unsatisfactory both on chemical and physical grounds.

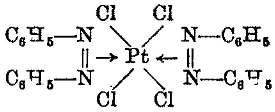
Adopting Walsh's suggestion, however, the mechanism whereby the co-ordinate bond is formed may be readily understood; thus, for example, the structure of the anion of Zeise's salt can be satisfactorily represented by



$$\left[\begin{array}{c} H_2C{=}CH_2 \\ \downarrow \\ Cl{-}Pt{-}Cl \\ | \\ Cl \end{array}\right]^-$$

On the basis of the above formulation of these olefinic co-ordination complexes, one might expect that the order of increasing co-ordination ability (as judged by the stability of the olefinic complexes) would run parallel with decrease in π^{-1} ionization potential. However, strict correlation between these two quantities may be counterbalanced by steric factors, which will also play an important part in determining the stability of the complexes. Thus Anderson (*loc. cit.*) has shown, for example, that *cis* configuration greatly promotes co-ordination.

Although in azoxy compounds lone pairs and not bonding electrons are donated, it is possible that in the co-ordination complex, which Kharasch and Ashford[7] have found to be formed between azobenzene and platinic chloride, bonding electrons are donated. The complex may be represented by



in which the azo → Pt bond is a π-electron dative bond, rather than a normal 'co-ordinate link' type of bond formed by the lone pairs on the individual nitrogen atoms.

In view of the general reactivity of the π-electrons in olefinic compounds, as exemplified in the electromeric change , and in donor properties, I would suggest that the conventional double bond formulation might with advantage be rewritten as . Such a formulation would attempt to distinguish between those electrons in the hybridized sp^2, σ bonds and the electrons in a pure $2p_z$ orbital which are responsible for the characteristic reactivity of olefinic compounds.

Influence of the Sugar Concentration on the Growth of Isolated Pine Roots

Some preliminary observations are submitted below concerning the culture of isolated roots of a coniferous tree species, *Pinus sylvestris*.

Seeds were collected in the province of Vermland, Sweden (Uddheden, Grasmark, 110 m. above sea-level). To obtain as uniform a rate of germination as possible[1] only the darkest seeds, which were the most numerous, were selected for the experiments. The seeds were disinfected by a 15-min. treatment with a solution of calcium hypochlorite according to Wilson's[2] and Melin's[3] techniques, and were then carefully washed in sterile distilled water. Germination took place at 20° C. on 1·5 per cent washed agar contained in Petri dishes. Root tips approximately 10 mm. long were removed from the seedling roots and transferred to 100 ml. Erlenmeyer flasks (Jena glass) containing 20 ml. of nutrient medium. This medium contained per litre of redistilled water (specific conductance at 18° C. $= 1{\cdot}09 \times 10^{-6}$ reciprocal ohms) the following mineral salts[4]: 50 mgm. $Ca(NO_3)_2$, 10 mgm. $MgSO_4$, 10 mgm. KH_2PO_4, 1 mgm. $FeCl_3$, 0·1 mgm. $Na_2B_4O_7$, 0·1 mgm. $MnCl_2$, and 0·1 mgm. $ZnCl_2$.

As source of carbon and energy use was made of (1) glucose (Pfanstiehl, "C.P. Grade") and (2) sucrose (Schering–Kahlbaum, *puriss.*). The media were supplemented with thiamin (1 γ per 20 ml.), and with biotin (0·001 γ per 20 ml.). The vitamin preparations used were thiamin hydrochloride Merck (Darmstadt) and biotin Merck (Rahway, N.J.).

The culture flasks containing the nutrient solutions were sterilized by autoclaving for 15 min. at a pressure of 1 kgm. per cm.^{2}, corresponding to a temperature of 120° C. The inoculated flasks were incubated at 20° C. for 60 days.

TABLE 1. INFLUENCE OF GLUCOSE CONCENTRATION ON THE GROWTH OF ISOLATED PINE ROOTS

Glucose, per cent	Average total length of 14 roots in mm.	Average number of branches
2	7·8	2·5
3	26·3	3·6
4	46·1	4·2
5	21·6	3·1
6	9·8	2·0

TABLE 2. INFLUENCE OF SUCROSE CONCENTRATION ON THE GROWTH OF ISOLATED PINE ROOTS

Sucrose, per cent	Average total length of 14 roots in mm.	Average number of branches
3·9	14·7	2·5
5·8	79·4	7·4
7·7	28·3	2·9
9·6	6·6	2·3
11·6	0·0	0·0

Some results obtained in assaying the influence of different sugar concentrations on the growth are listed in Tables 1 and 2. In these experiments the nutrient solutions contained 2–6 per cent glucose or of sucrose in a corresponding molarity (3·9–11·6 per cent). The optimum glucose concentration was found to be 4 per cent, while the optimum sucrose concentration was 5·8 per cent, in molarity equivalent to 3 per cent glucose.

Sucrose gave rise to considerably more powerful growth and more branches than glucose, and may hence be a more suitable source of carbon for isolated pine roots than the latter.

The investigation is being continued.

Mendelian Inheritance in New Zealand Romney Sheep

THE present purpose is to report further changes in our views on the genetics of *N*-type sheep. As stated and illustrated previously[1,2,3], these animals have very high abundance of halo-hairs in the birth-coat, and their fleeces are usually hairy, that is, have much medullation. Of our four *N*-type stocks, one has been called 'multifactorial-*N*', two are 'dominant-*N*' and one 'recessive-*N*'.

The so-called multifactorial-*N* stock is related to both dominant-*N* stocks, Nielsen-*N* and Massey-*N*. Evidence from experiments not quite complete points to the *N*-gene being the same in both dominant stocks. Breeding tests still in progress make it probable that the 'multifactorial' stock is multifactorial only for modifiers aiding the expression of the dominant-*N* gene. The foundation animals, among the descendants of which selection for *N*-type proved rapidly successful, all had many halo-hairs, but fewer than *N*-type. The original ram, which was horned, and to which the whole stock is traceable, and several of the earliest ewes, were so bred that they could be heterozygous for the dominant-*N* gene. By this time we are familiar with the fact that the dominant-*N* gene may come to poor or even very poor expression in heterozygotes. Finding ourselves thus without any stock that can be regarded as multifactorial in the sense that no one gene plays a major part, we are the more anxious that the genetics of the coats of the hairy mountain sheep of the northern hemisphere should be studied.

Our central problem is the relation between dominant-*N* and recessive-*N*. For four years the hypothesis under test has been that dominant-*N* was a duplication of recessive-*N*. The two genes would then be allelomorphic. *N*-type sheep have been secured from the mating of recessive-*N* and dominant-*N*. Two such recessive-dominant *N*-type rams have been mated with recessive-*N* ewes. The lambs are 20 *N*-type; 7 non-*N*. Four of the non-*N* lambs are by one ram, three by the other. This is the 3 : 1 ratio expected if the genes are independent. The hypothesis is therefore no longer tenable. We are the more anxious to announce this result because reference has been made to this hypothesis by Prof. Ruggles Gates[4,5]. Sheep-breeding experiments take a long time, and it is therefore our policy to pass ideas to fellow-workers in a manner which would be thinking aloud too much if mice were our material.

Recently, we enjoyed the privilege of discussing this work with Prof. Richard Goldschmidt during his visit to New Zealand. He pointed out how often the same character in *Drosophila* is conditioned by different genes, and told us that the simplest interpretation is complete independence of the dominant-*N* and recessive-*N* genes. There is, however, evidence from breeding results, the critical discussion of which would take too much space, which allows us still to wonder whether the two genes, though resident on different chromosomes, may indeed be the same. It is suggestive, too, that in both dominant-*N* and recessive-*N* sheep the same pleiotropic effects occur. The problem is being tackled by further breeding, and one of us (A. S. F.), whose earlier research has been in plant cytogenetics, is studying the chromosomes of rams of different genotypes.

The fact that the two genes are carried by different chromosomes gives greater scope for the study of dosage effects. Horns in ewes, for example, are the rule in homozygous dominants; small horns are frequent in recessive-dominant ewes; horns occur occasionally in heterozygous dominants; and they have not yet been recorded in recessive-*N* ewes. Other characters are being studied in the series of genotypes, notably the abundance of the several fibre types of the birth-coat.

Our attention has recently been directed to the possible application of this fundamental work. In the early days of this College, research was started on hairiness because it was regarded as a wool fault. Then the emphasis came to be put on the genetics of *N*-type. Early in 1946, Prof. A. F. Barker visited New Zealand and spent several days at this College. He urged the breeding of *N*-type sheep on a larger scale in order to supply one of the world's best carpet wools.

'Foveal Tritanopia'

IN his book on colour vision, Dr. W. D. Wright[1] discusses blue-blindness of the retinal fovea, which was described by A. Koenig[2] fifty years ago and is now maintained by Willmer[3] and himself for the same reasons: "This effect does not appear to have been the subject of further extensive study and although other workers were aware of Koenig's observation the general attitude appears to have been one of scepticism. Indeed most people either ignored or were ignorant of the phenomenon until Willmer recently reawakened interest in the subject." Dr. Wright has apparently overlooked the controversy between E. Hering and A. Koenig.

Koenig's[2] hypothesis that the visual purple and yellow are the photochemical substances for grey and blue sensations, the rods the colour-receptors, and the cones only dioptric means to throw the retinal images on the rods, led him to the assumption that the purple-free fovea were blue-blind. His observations with colour equations seemed to confirm his assumptions, as in the case of Drs. Willmer and Wright.

Hering[4] attacked Koenig's observations and conclusions in a paper noteworthy for its concise reasoning and the sharpness of its criticism. Hering showed that direct foveal observation of small blue test objects demonstrates the perfect blue-sensation of the fovea, provided that some precautionary measures are taken which he prescribed with exactness, and that the fovea is the most colour-sensitive spot of the retina.

Conclusions from colour equations and colour-matches on such small retinal fields as the fovea led Koenig to the error of foveal blue-blindness. Colour equations are only valid under three conditions: that the test is of sufficient brightness, that the retinal field has a minimum size, and that the eye is not tired. Hering had shown already in an older paper[5], before Koenig's publication, that the validity of colour equations is limited and that the latter are not valid on very large fields or very small retinal fields such as the fovea. Colour equations with blue-green mixtures need much more blue on small retinal fields such as the fovea (1893). Koenig's short reply[6] was not convincing at all; a more detailed one was promised but never published—a later paper of pathological blue-blindness due to ablatio retinæ and retinitis has nothing to do with the problem in question. Hering[7] replied and again refuted concisely foveal blue-blindness and Koenig's strange theory of the function of rods and cones, just at the time of the making of the duplicity theory. Everyone of that time interested in the subject knew of Koenig's publication and his lecture at the Academy of Sciences in Berlin, and also of the controversy with Hering. There is little doubt that authorities of those days such as v. Kries, Lord Rayleigh and Nagel put such an important question to the test, as was easily done from Hering's description.

Many years after Koenig's death, Sir John Parsons[8] rejected strongly foveal tritanopia in his standard work on colour vision, saying, "This observation (i.e., Koenig's) is certainly untrue". Curiously, he did not cite Hering on this question, although he quotes him otherwise more than sixty times in his excellent book.

Recently, Prof. H. Hartridge[9] has rejected foveal tritanopia for precisely the same reasons as E. Hering in the old days, showing in detail that colour equations are not valid on retinal fields so small as the fovea, and direct foveal observation of blue tests gives clear blue response. But there is again no reference to the work of Hering or Helmholtz[10]; the latter was aware of these facts even before Hering. These facts are not at all recent advances, but apparently they have been forgotten nowadays.

ALL workers on colour vision will, I am sure, welcome Dr. Karplus' letter, especially for the historical notes on the dispute between Koenig and Hering. It is quite evident from this that the dichromatism of the central fovea, when reported by Koenig fifty years ago, was the subject of some heated discussion; at the same time, when Willmer[1] re-discovered the effect in 1944, it is probably true to say that most workers in the subject had either ignored or were ignorant of both Koenig's results and Hering's discussion of them, and I would have to admit to being among that number. No doubt there were exceptions, and Dr. Karplus is certainly one honourable example; but then I understand that he had the great privilege of working under Koenig in his laboratory—a privilege that may well be unique among those alive to-day.

With regard to the phenomenon itself, I think it should be made clear that the recent observations by Willmer[2], Thomson[3] and myself completely substantiate Koenig's original colour-matching experiments. I suspect that many of the difficulties and differences of opinion that have arisen in explaining the dichromatism have had their origin in the different connotations applied to the word 'dichromatism' and also to the misuse of the word 'blind'. As generally understood at the present time, dichromatism implies that colour matching can be carried out by the mixture of only two matching stimuli, and it is in this sense that the central fovea has been described as dichromatic, and not in the sense of there being only two qualities of sensation associated with its stimulation. The misuse of the word 'blind' is quite extensive in the frequent description of persons with defective colour vision as being 'colour-blind', although the great majority are in no sense blind to any of the radiations in the visible spectrum, since their essential defect is a reduced ability to discriminate the colour quality of one wave-length from that of another. In the same way, it is incorrect to refer to tritanopia as 'blue-blindness'. The radiations at the short-wave end of the spectrum may be perfectly visible and may even give rise to the sensation of blueness, yet at the same time a tritanope or a tritanopic area of the retina will have a reduced ability to discriminate colours in the blue-green region of the spectrum. It is true that observations by Thomson and myself[3], and other measurements reported by Dr. W. S. Stiles at Cambridge last July during the International Colour Vision Conference, show that some loss of blue sensitivity may occur in the central fovea, but we have not suggested that the fovea is blind to these radiations.

Koenig's interpretation of the dichromatism was no doubt in error. It is, however, important not to condemn the experiments along with the theory, and I have no doubt at all about the fundamental soundness of Koenig's original observation of foveal tritanopia, nor of Willmer's re-discovery of the phenomenon.

Visual Cells of the Guinea Pig

The statement of Granit[1] that the guinea pig has a "pure rod eye" calls for comment. Franz[2], referring to a paper of his own published in 1909, says that cones are missing from the retina of the guinea pig. Ovio[3] admits the presence of a few cones. Kolmer[4] describes cones and rods. He makes the significant remark that observation prior to his own had been made on poorly fixed material. Rods are four to five times as numerous as cones, and he comments on the clear vacuoles at the peripheral end of the cone myoids.

Preparations of my own made nearly ten years ago confirm the findings of Kolmer. Neither the cornea nor the lens is as large as one would expect in an eye populated only by rods. The ratio of nuclei in the outer layer to that of the bipolars is four, or at the most five, to three (excluding the nuclei of Müller's fibres), a much lower ratio than one expects in a pure rod retina. In the dog it is twelve to four at least, and in a jerboa mouse (*Notomys cervinus* Gould) sixteen to five. These ratios are only approximate, but are an indication of the amount of summation of impulses in the retinæ of these two eyes rich in rods. The eye of the dog is larger than that of the guinea pig, that of the Jerboa mouse smaller. Cup-shaped vesicular areas in the outer molecular layer of the guinea pig's retina suggest that some of the visual cells have dendritic foot-pieces. In my own preparations the cone myoids project beyond those of the rods. The tip of the distal segment of the cone is enveloped in a process of the pigment epithelium, and in areas where the visual cells have lost touch with the pigment epithelium, the cones do not part company with it as easily as do the rods. This enveloping of the tip of the cone has been commented on in the human retina by Walls[5] and Kolmer[6].

To the histologist, the retina of the guinea pig is certainly not 'pure rod'.

Sound Emitted by Dolphins

During a cruise in the Mediterranean last year on board the Swedish research ship the *Skagerak*, I happened to notice that the dolphins (*Delphinus delphis*) uttered sounds that were quite audible on board the ship, though the dolphins were swimming one or two metres below the surface. The sounds may be described as short, rapidly repeated squeaks rather like those produced by fighting or playing mice. As I had many opportunities of listening to the sounds, sometimes with the ship at rest in calm weather, and had several other persons verify the observation, there can be no doubt as to the ability of the dolphins to produce audible sounds.

Elemental Nomenclature

It may be presumptuous for a zoologist to speak to a chemical question. However, the points raised by Vallarta and Arnaiz y Freg and by Webb in *Nature* of August 12, pp. 163–64, are on all fours with problems of nomenclature familiar to biologists. Del Rio's erythronium was validly published and, from a zoological point of view, his subsequent disavowal was an ineffective act. The chemists are well advised in being cautious about the unreasoning application of the rule of priority. Since the number of elements seems unlikely to be much in excess of a hundred, the problem is quite simple compared with the handling of some 200,000 generic names of animals. Hence the homonymy between two uses of plutonium causes no confusion. Perhaps a new rule might read that if a name has had no employment for fifty years, whether or not withdrawn by its author, it shall become a *nomen vacuum*, with the recommendation that such names should not be re-used with a new meaning. Finally, this rule or any other nomenclatorial rule should not be applied retroactively, since there is an implied contract between the rules and the public that a change in the rules shall not render a previously legal usage illegal. The lawyer calls this *stare decisis*.

"Miracles"

In my recent review of Mr. C. S. Lewis' book on "Miracles", I wrote that what are described as miracles "occur most freely in periods when critical skill is least". From Mr. E. V. Burke, writing from 27 The Crescent, London, S.W.13, I have received references to the following books on cures recorded at Lourdes: E. le Bac, "Medical Proof of the Miraculous, a Clinical Study" (1922), and G. Bertrin, "Lourdes, its Apparitions and Cures" (English translation by Lady Gibbs), and the *Catholic Medical Guardian*, 1933–34 (case of Pierre de Rudder, broken leg cured instantaneously), which may not be generally known.

I have only to add that I did not say that such cures do not occur when (or where) critical skill is adequate; and Mr. Burke himself writes that "many claimants to miracles are completely rejected" at Lourdes.

Oxford.

PUBLICATION AND CLASSIFICATION OF SCIENTIFIC KNOWLEDGE

THE direct importance to the research worker of an efficient scientific information service led the Cambridge Branch of the Association of Scientific Workers to hold a conference on October 25 to discuss various schemes that have been proposed. Although the subject had been discussed previously by professional abstractors and librarians, this was the first conference of 'users' of scientific information.

The chairman, Sir Lawrence Bragg, outlined the two main aspects of the problem: (*a*) how are scientific workers to get to know of the work that interests them, and (*b*) having learned of it, how can they get a copy of the actual publication. The first is by far the more difficult. As regards the second, the personal contact provided by correspondence is invaluable, and any centralizing scheme must avoid destroying this.

Prof. J. D. Bernal divided scientific information into 'operative units' according to their length and function (see table). Thus the scientific 'paper' is the operative unit, not the journal. Abstracts should be of two kinds, 'indicative' and 'informative'. The former merely guides you to the paper while the latter should be full enough to be adequate for 'background' reading. By the term 'thesis', he means the fullest possible account of a piece of research, not necessarily a dissertation for a doctorate. He proposed a single subscription to a national distributing agency which would entitle one to receive automatically, say, 1,000 papers a year plus abstracts of a given field or fields. Further papers or theses could be obtained on request.

	BOOKS > 50,000 words	PAMPHLETS 10,000–500,000 words	PAPERS 5,000–100,000 words	LETTERS OR NOTES 100–5,000 words	ABSTRACTS OR TITLES < 100 words
EPHEMERAL		§ Research programmes	Lectures	Letter on work in progress	Title of research project
OPERATIVE		† Theses (full experimental detail and mathematical argument)	*† The scientific paper	*† Note or informative abstract	* Indicative abstract
COLLECTIVE		Monographs	*§ Report (e.g., annual) on progress of a subject	Book reviews and critical articles	§ Bibliographies
DEFINITE	Treatises		§ Handbooks	§ Data tables (fauna – flora, maps, etc.)	§ General indexes
UTILITARIAN	Text-books. Popular science books	Practical monographs	Technical articles	Technical notes	

Note.—The four essential units are outlined with heavier rules.

* To be received automatically. † To be received on request through agency. § Central responsibility for preparation.

Those present at the conference agreed generally with this scheme, provided that the scientific journals continued also to be available in bound series in libraries. Prof. R. S. Hutton pointed out the present and future financial difficulties of the societies in publishing their journals, and suggested that a proper financial arrangement with such a national distributing agency might be decisive in obtaining their agreement to the scheme. Mr. J. W. S. Pringle emphasized that editorial responsibility must rest with the societies, and that it is really a question of the suggested agency buying the copyright and a large number of reprints. Dr. E. Orowan and Prof. Hutton quoted a number of societies, mainly in the metallurgical and engineering fields, which are, in fact, partially operating the proposed scheme, as they treat the paper as the unit and later assemble them into *Transactions*.

Whether reprinting is the most economical method of reproduction was doubted by Mrs. Lucia Moholy, and she gave figures to support the use of micro-filming, particularly when the demand could not be forecast. Dr. D. P. Riley praised the microfilm service run in conjunction with abstracts published by the Centre National de la Recherche Scientifique in Paris, and said that the French Thomson-Houston microfilm-viewer is very good. In discussion, the need for an efficient and cheap British microfilm-viewer (costing about £30) was underlined.

The different needs of the biological and physical sciences were referred to by several speakers. The abstracting service of the Imperial Bureau of Plant Breeding and Genetics was described by Mr. R. H. Richens, while Prof. H. Jeffreys dealt with the position in astronomy, meteorology and geophysics. It was agreed that abstracting should always be done in one of the common European languages. Some interesting suggestions were made with reference to the classification and indexing of scientific papers, and the need for a fundamental theory of classification was made obvious. Most speakers favoured, as an immediate measure, the extension of the Universal Decimal Classification to meet the requirements of new branches of science such as nuclear physics. Mr. J. B. Hasted suggested that the cross-referencing difficulty might be overcome by using a matrix system. Dr. S. Lilley objected to the use of the decimal system, as classification on a binary scale is much more efficient and flexible. The logic of classification is better on a dual system and is ideal for use with machines. His own simple knitting-needle and punched-card system gives the possibility of 10^{33} classes on one card.

An editor's opinion was given by Dr. R. C. Evans. He compared American and British practice; he is convinced that many of the reasons for delays in publication lie in the form in which papers are submitted. The increased speed of communications should logically lead to the creation of international journals such as the old *Zeitschrift für Kristallographie* and the new *Acta Crystallographica.*

Some indication of the need for rationalization was provided by figures given by Prof. Hutton. The number of worthwhile scientific periodicals is 15,000, and the number of original papers in these journals is about 750,000 per year. Of these, 1 in 3 are abstracted; but it should be noted that chemistry accounts for a great number as it is the most thoroughly abstracted branch of science.

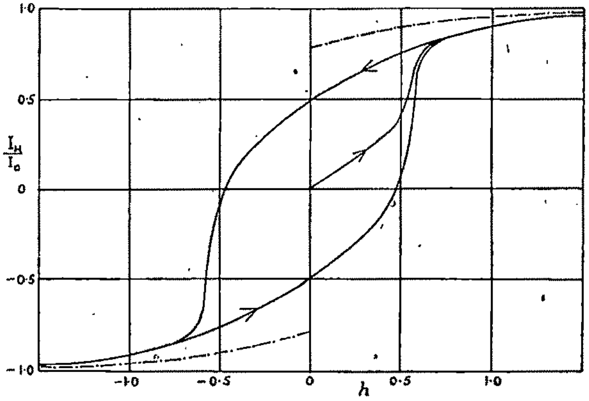
INTERPRETATION OF HIGH COERCIVITY IN FERROMAGNETIC MATERIALS

By PROF. E. C. STONER, F.R.S.,
AND
E. P. WOHLFARTH
Physics Department, University of Leeds

IN the generally accepted theory of the ordinary magnetization curves of ferromagnetics, due to Becker, Kersten and many others, and fully described by Becker and Döring[1], coercivity is related to the amplitude of internal stress variations through their effect on domain boundary movement. Although there can be little doubt as to the correctness of the basic ideas, or to their wide applicability, the treatment cannot account for coercivities of 500 oersted, and more, which are obtained in modern permanent magnet materials, without arbitrary and improbable assumptions about the magnitude and character of the internal stress variations. It occurred to one of us some years ago that for those alloys of the dispersion-hardening type for which the higher coercivities are found, an entirely different type of explanation might be possible, and some preliminary calculations gave promising results. This line of inquiry was interrupted by the War, and no more than vague references to it have been published[2], though it has been discussed verbally and in correspondence with others interested. A systematic attack on the problem was resumed at the beginning of 1946, and a full account of the work has now been prepared. In view of the inevitable delays in publication a brief account may be appropriate here. It may be stated quite frankly that the immediate stimulus to this communication has been two short and admirable papers by Néel[3], which have just appeared, and which show that he has been thinking along similar lines with particular reference to powder magnets.

The central idea is that in many ferromagnetic materials there may occur 'particles' (this term including both actual powder grains and atomic segregates or 'islands' in alloys), distinct in magnetic character from the general matrix, and less than the critical size, depending on shape, for which domain boundary formation is energetically possible. For particles in the form of ellipsoids of revolution, a reasonably precise expression for the lower limit to this critical size is obtained, involving the saturation intensity, I_0, and the Curie temperature of the material of the particle and the smaller demagnetization factor. For spherical particles, the lower limit to the critical diameter is found to be $0{\cdot}8 \times 10^{-6}$ for iron, and $3{\cdot}1 \times 10^{-6}$ for nickel, the number of atoms in the volume being about $1{\cdot}5 \times 10^{6}$ and $1{\cdot}2 \times 10^{7}$ respectively. For prolate spheroids of dimensional ratio 10, the diameters are some four times as great, and the number of atoms $1{\cdot}1 \times 10^{9}$ and $8{\cdot}1 \times 10^{10}$. In such single-domain particles, change of magnetization can take place only by rotation of the magnetization vector, I_0, which remains constant in magnitude and uni-directional throughout the particle. As the field changes continuously, the resolved magnetization in the field direction may change discontinuously at critical values of the field. The character of the magnetization curve depends on the degree of magnetic anisotropy of the particle, and on the orientation of the 'easy axes' with respect to the field. The magnetic anisotropy may be due to anisotropy of shape (the energy depending on direction owing to the directional dependence of the demagnetizing field), magnetocrystalline anisotropy or strain anisotropy.

A detailed quantitative treatment has been developed of the effect of shape anisotropy when the particles are in the form of ellipsoids of revolution, and a less detailed treatment for the general ellipsoidal form, of which the prolate and oblate spheroid are limiting cases. In dealing with ellipsoids of revolution it is convenient to use a non-dimensional parameter h, defined by $h = H/|(N_a - N_b)|I_0$, where N_a and N_b are the demagnetization coefficients along the polar and equatorial axes. The variation with h of the ratio I_H/I_0, where I_H is the resolved value of I_0 in the positive field direction, has been determined, by accurate numerical solution of the equilibrium equations, for a series of angles, θ, ranging from 0° to 90°, of the orientation of the polar axis with respect to the field, and also for random orientation. The magnetization curves for random orientation are shown in the accompanying figure, where the full curves refer to prolate spheroids, the broken curves to oblate spheroids.



For the special limiting case of the oblate spheroid, there is no hysteresis (this applies to all orientations), though there is a discontinuous change in the magnetization as the field passes through zero. For the prolate spheroid, exact expressions are obtained for the critical field, h_0, at which the discontinuous change occurs, and for various related quantities, as functions of the orientation angle, θ. As θ varies from 0° to 90°, the cyclic magnetization curves change from a rectangular form, with $|h_0| = 1$, to a linear non-hysteretic form, with an interesting sequence of intermediate forms. The lowest value of $|h_0|$ is $\frac{1}{2}$, occurring for $\theta = 45°$.

All the numerical results are applicable when the anisotropy is due to longitudinal stress, when h and H

are related by $h = HI_0/3\lambda\sigma$, where λ is the saturation magnetostriction coefficient, and σ is the stress. If λ and σ are of the same sign (as for nickel under compression and approximately for iron under tension) the behaviour is similar to that of prolate spheroids; when the signs are opposite, to that of oblate spheroids. The results also apply to magnetocrystalline anisotropy in the important and representative case in which there is a unique easy axis of magnetization, as for hexagonal cobalt; in this case, h and H are related by $h = HI_0/2K$, where K is the magnetocrystalline anisotropy coefficient.

In general, all three types of anisotropy may be present, and an estimate of the relative magnitudes of the effects is important. For magneto-strain anisotropy, assuming as a reasonable upper limit of the stress, σ, a value of 200 kgm.mm.$^{-2}$, the maximum values of H/h for iron, nickel and cobalt are about 600, 4,000, and 600 respectively. For the magnetocrystalline effect, H/h is about 6,000 for cobalt; for cubic crystals, the numerical results obtained do not apply in detail, but the maximum coercivity may readily be estimated as about 400 for iron, and 200 for nickel. For shape anisotropy, H/h has a maximum value (for elongated particles) of $2\pi I_0$, giving about 10,800 for iron, 3,200 for nickel and 8,900 for cobalt; even for a dimensional ratio as low as 1·1, the values are 810, 240 and 670 respectively.

Although the mechanism outlined, involving magnetically anisotropic single-domain particles, may be involved to some extent in a wide range of ferromagnetic materials, there are three types of materials in which it is likely to be of predominant importance. These are (1) powder magnets, (2) non-ferromagnetic metals and alloys containing ferromagnetic 'impurities'[4], and (3) high coercivity alloys[5] of the dispersion-hardening type. Néel's papers are concerned particularly with powder magnets, which have been greatly developed in France in recent years, and about which little information was accessible to us. A survey of the literature on (2) and (3) leaves little doubt that the 'single-domain particle' mechanism provides in many cases a more satisfactory interpretation of the observed magnetic characteristics than any other that has so far been suggested. As the coercivities are often in the region of 500, it is usually not possible from the evidence available to draw definite conclusions as to the type of magnetic anisotropy primarily involved, though with coercivities appreciably greater than this, and with 'iron-like' segregates, there is strong presumptive evidence of some degree of shape anisotropy. For alloys of the alcomax or ticonal type, for which the remarkable effect of cooling in a magnetic field is well known, but not satisfactorily explained, it is significant that the demagnetization curves along and perpendicular to the direction of this field are strikingly similar to those for single-domain particles with a unique easy axis of magnetization aligned at nearly 0° and nearly 90° to the applied field. This suggests that cooling in a field favours a preferential growth of single-domain segregates with easy axis along or near the field direction.

THE MELLON INSTITUTE

ANNUAL REPORT FOR 1946–47

REVIEWING the post-war plans of the Mellon Institute of Industrial Research in the thirty-fourth annual report, the director, Dr. E. R. Weidlein, refers to the loss by the Institute since 1942 of many able scientific workers and to the difficulty, in view of the general shortage of scientific man-power, of acquiring the staff required for expansion. It is a part of the Institute's responsibility to foster the training of research workers, however, and of 609 'fellows' who left the Institute during 1913–46, forty per cent took up appointments with the donors of their fellowships and 6·7 per cent with other donors. The average term of service of these fellows was four and a half years, as compared with an average of 7·2 years for fellows now in the Institute. During 1946–47, the Institute had 295 fellows in applied science with a further nine in the department of research in pure chemistry and five in that of research in chemical physics, together with a total of 283 associates, assistants and laboratory technicians. Eighty industrial fellowships were in operation during the year, of which fifty were multiple fellowships. Six fellowships had been proceeding for thirty years or more, two for at least twenty-five years, nine for fifteen years and nineteen for at least ten years.

The Department of Research in Pure Chemistry continued to focus attention on synthetic organic chemistry as applied to biological and chemotherapeutic problems, and in a study of the nitrophenyllepidylcarbinols, good yields of the *m*- and *p*-nitrobenzylidenedilepidine compounds have been obtained. A series of substituted 4-amino-6-β-hydroxyethoxyquinolines was prepared, as well as some quinoline azomethines and their hydrogenation products. The comparative properties of 2- and 4-mercapto-7-methylquinoline have been investigated, and the study of specialized uses of hydroxyethylapocupreine and related derivatives in chemotherapy has been resumed and extended. Research has been advanced on the reactivity of esters of *p*-toluene sulphonic acid towards sodium iodide dissolved in acetone. Investigation of the kinetics of the reaction of substituted ethyl benzene sulphonates with sodium ethoxide in ethyl alcohol indicates that the reaction is of the second order, and some attention has been given to the synthesis of the substituted benzene sulphonyl chlorides. Use of cyclic alkylene carbonates and sulphites for hydroxyalkylation of phenols, amines and mercaptans has been extended to esters of 1 : 2- and 1 : 3-glycols. The chemistry of pyrimidine derivatives, correlated with heterocyclic structures of biological importance, is also under investigation.

The Department of Research in Chemical Physics has completed a precise re-determination of the lattice constant of lead, and with the nickel fellowship has contributed a joint paper on X-ray diffraction of nickel–aluminium alloys. The quantitative analysis of crystalline mixtures by means of the Geiger-counter spectrometer, the determination of molecular structure through the analysis of infra-red and Raman vibration spectra and the design of absorption cells, instruments and techniques for Raman, infra-red and ultra-violet investigations of pure hydrocarbons in the liquid phase and under pressure are also receiving attention.

Ceramic investigations have included the utilization of bentonite in compounding plastics as an extender rather than as an inert filler, and one such type of compression-moulding plastic has reached pilot-plant production. A recent fellowship on white cover-coats of high titania content has been successfully directed towards better colour values, ease of application and lighter application weights. In the metallurgical field, studies of the effect of heat treatment on the physical properties of iron powders have led to the establishment of specific processing methods, and encouraging results have been obtained in the use of specially processed silicon carbide, 'Ferrocarbo', in steel making and cast-iron founding. A multiple fellowship of the Scaife Co. has led to a better understanding of the strain patterns with variation in design of pressure vessels, especially the strain concentrations in the walls at service and testing pressure, and arc welding is being investigated as a more economical method of fabricating thin-walled pressure vessels. In a multiple fellowship on the utility of silica gel – supported catalysts for promoting hydrocarbon reactions, fairly definite conclusions have been reached for one type of catalyst on the relations between silica support and the activating materials conducive to activity. Research on gas by-products, in addition to providing the basis for the manufacture of polystyrene at Koluta, Pennsylvania, has led to methods for the removal of hydrogen sulphide in low concentrations from gas rich in carbon dioxide and for the production of ammonium sulphide from hydrogen sulphide from coal gas by the Koppers sodium carbonate hot-vacuum process. The phase relations of maleic anhydride, with particular reference to its recovery from the oxidation products of benzene, the properties of plasticized pitches, particularly rheological properties over wide extremes of temperature, the hydrogenation of anthracene cake and the oxidation of cyclohexane and ethylcyclohexane in the liquid phase and of naphthalene and benzene in the vapour phase are other subjects investigated under the fellowships of the Koppers Co., Inc.

In the petroleum field, studies of the chemical correlation of crude oils and bituminous materials have been extended, and new and more precise methods of separation and new correlations of physical properties have permitted better comparisons. The controlled polymerization of selected olefins to specific isomers has been effected, and progress made in determining the constitution of new types of sulphur compounds derived from olefins. A new class of anti-oxidants has been developed, and work with radioactive C^{14} on the mechanism of the Fischer–Tropsch synthesis has been particularly fruitful. Under the Carbide and Carbon Chemicals Corporation's multiple fellowship for organic synthesis, hydraulic brake fluids based on the 'Ucon' lubricants have been developed, and another member of the 'Ucon' family, 'Flexol Plasticizer B-400', relieved the castor oil shortage for the cloth-coating industry. An improved softener and flame-retarding composition for treating decorative paper products was also developed; and in addition to the modification of wool to increase resistance to insect attack and shrinkage, anti-static treatments for synthetic fibres are being investigated.

In the field of food products, a preliminary study has been made of the retention of folic acid in strained foods, and a new absorbent for refining sugar has been developed which can replace bone black without change in refinery practice. Work on zein has led to new dispersion systems for the preparation of coatings, inks and pigment binders; and a new technique for handling zein has yielded solutions promising for back-sizing mastic tapes and for use as undercoats to prevent absorption of nitrocellulose lacquer. Esters of inositol with drying oil fatty acids have excellent colour and cook rapidly to very clear, light, hard varnishes, while alkyds from inositol have possibilities as varnish modifiers and plasticizers for films. A suitable process has been worked out for the analysis and control of mildew-proofing agents for treating military equipment, and investigation of sizing compositions for knitting nylon hosiery yarns as well as fundamental studies of felts and felting processes are also in progress.

A wood-like product has been made from waste wood, comparable to the original wood in nailing and sawing qualities, and is now at the pilot-plant stage. Satisfactory progress has been made with a programme for controlling by instruments the continuous manufacture of *GR-S* rubber from butadiene and styrene, and a new type of chlorinated rubber, characterized by its flexibility and toughness, has been developed. An organic coating system to extend the life of steel condensers and of heat exchanger and boiler tubing has been developed and a new technique for formulating such coatings examined. Both the fundamental chemistry and the practical applications of organo-silicon compounds have continued to receive study, and the silicone fluids, through their low vapour pressure, wide range of fluidity and stability to high temperature, have solved a heating problem where pressure lines for steam or other vapours are impracticable or uneconomic. An insecticidal fellowship of the Rex Research Corporation, under which in the course of thirteen years five hundred new compounds have been prepared and tested, has now led to the use of piperonyl butoxide and piperonyl cyclohexenones on a large scale, while other compounds have shown promise. Petrolatum research has yielded a sterile petrolatum gauze burn-dressing in convenient, individual package form, and a group of hydrophile ointment bases, capable of being sterilized, with definite therapeutic properties. A method for the determination of polyethylene glycols in biological fluids has been developed, and their chronic physiological effect examined. The Industrial Hygiene Foundation has been further strengthened during the year, and a new professional committee on chemistry and toxicology appointed.

ELECTRONS AND THEIR UTILIZATION

DURING the present century, a new 'slave-trade' has arisen. Individuals are torn from their native element and are made to perform functions entirely foreign to them; immense coercion is applied to make them perform these functions; and when they have performed them they are carelessly discarded. Since the existence of these individuals—electrons—was first recognized fifty years ago, man has transformed out of all recognition his power and control over them. We are now not sure of the exact nature of the electron. Is it a particle or a wave packet? But whatever it is, wave-mechanics leads to no suggestion that the electron has a soul;

and so man can, for the present, continue his slave trade without any qualms of conscience.

The exhibition arranged by the North-West Branch of the Institution of Electronics and held at the College of Technology, Manchester, during July 22–23, might justly be described as a tour of the torture chambers of the electrons, the scale of tortures being finely graded from the mere interchange of habitat, as in accumulators, to the dragging out into free space and violent oscillation that occurs in high-frequency valves. In fact, this gradation provides a convenient basis for the classification of the various items that were shown in the exhibition.

The Chloride Electrical Storage Company exhibited many examples of accumulators and an interesting set of illustrations of rather unusual uses. These were happily chosen to cover a wide field—from the upper atmosphere (in *radio-sonde* apparatus) to below sea-level (the detection of fire-damp in mines). And to hint at more drastic electronic exercises, a portable oscilloscope was shown.

The various types of discharge lamps might well form the next subject. In these, electrons are caused to collide with the molecules of a rarified gas, which is thereby ionized; the return to the stable state is manifested by the emission of light, and, so far, this method of producing light is the most economical of power. It has, however, other advantages: it can be made almost instantaneous, by discharging a condenser through the lamp; and it can be used for stroboscopic purposes, by causing the discharge to occur periodically. Siemens showed examples of photographs taken with their 'Sieflash' argon lamp, which can produce an intensity of more than 10^8 lumens in a single flash lasting 10^{-4} sec. Ferranti's showed examples of their neon-filled 'Neostron', which is particularly designed for stroboscopic purposes.

The next stage of complication may well be taken as the radio valve; many examples were shown by Mullard's, Ferranti's, Cossor's and B.T.H. Particularly outstanding were the Mullard water-cooled 20 kW. valve and their valves made of silica, the internal construction of which was shown by sectioned models.

In addition to making electrons oscillate, we can subject them to lateral forces; this leads us to the cathode ray oscillograph—that 'maid-of-all-work' of the modern laboratory. Numerous examples of the utility of this instrument were shown, ranging from the visual observation of the electrical changes that occur in heart-beats (the Cossor electrocardiograph) to the vibration analyser of G.E.C. and Mullard. Many standard models were also shown by various firms, with suggestions for the different ways in which they can be utilized. Of particular interest were the small G.E.C. Miniscope and the Ferranti exhibit showing electron diffraction by an internally mounted specimen of zinc oxide.

Although interest was mainly centred on electrons, some space was also devoted to the means whereby electron convolutions are made possible—that is, the production of high vacua. Metropolitan-Vickers showed models of their pumps and pressure gauges, and a sectional model of a demountable X-ray tube in which these are used. Edwards also showed examples of modern pumps and the various oils used in them. People who use high-vacuum equipment are perhaps apt to take this side of their apparatus for granted, and these two stands should have helped to impress on such people that vacuum production is still a skilled art, and that improvements are continually being introduced in the process.

The range of application of all these devices was illustrated by many examples, and mention of only a few gives some idea of the uses to which electronics can be put in modern industry. There were a potentiometric titration apparatus, a layer-thickness meter for non-magnetic coatings on magnetic bases, a moisture-in-timber meter, controls to provide constant meter speed independent of load, dielectric heating for insulators or poor conductors, spot-welder control for accurate reproduction of welds, and cloth-guiding equipment for use in mills.

In short, one gained the impression that there was nothing that electrons cannot do, given the guiding hand of science behind them, and the exhibition fully served its purpose in directing attention to these powers. But largely it was preaching to the converted, and many looked with envy on the instruments that they could not purchase, or that they could only be promised months or years hence. If exhibitions such as this show us the golden age of the future, they also impress upon us the fact that it has not yet begun, and that a great deal of hard and concentrated work is necessary before we can usher it in.

NO PEARLS IN COCO-NUTS

DR. A. REYNE has recently published a detailed description of work carried out during the War "On the Structure of the Shells and Pearls of *Tridacna squamosa* Lam. and *Hippopus hippopus* (Linn.)" (*Arch. néerl. Zool.*, **8**, 206; 1947). The structures of the pearls and shells were studied by grinding surfaces in different directions, by examination of thin splinters, by slow solution in acids and by X-ray diffraction photographs. The author unfortunately lost his collection during enemy action at Wageningen in 1944 and 1945, so that a thin-section study has still to be made, and in the absence of photographs of some pearls and sections he has supplied text-figures drawn from his notebook sketches.

The structure of the *Tridacna* shell is elaborated in greater detail than in O. B. Bøggild's "The Shell Structure of the Molluscs" (1930), and the author claims to have written the first description of the *Hippopus* shell. X-ray powder photographs of the shell and the pearls of the species described show that the chief inorganic component is aragonite. The orientation of the fibrous crystallites of aragonite revealed by a photograph of a chatoyant pearl has not, however, been studied in detail.

Dr. Reyne was chief of the Coco-nut Research Station at Menado (Celebes) 1930–33 and examined the collection of "Coco-nut pearls" of the late Dr. J. G. F. Riedel, who claimed to have found one in a coco-nut which he opened himself (*Nature*, **115**, 138; 1925). Dr. Reyne concludes that these are all true *Tridacna* pearls and that Riedel had been deceived by some trick of the natives. Even in 1835 Quoy and Gaimard were already of the same opinion, who writing of *Tridacna* said "c'est aussi le lieu de parler de ces perles assez grosses, mais peu régulières, que secrète le manteau, et qui, dans plusiers endroits de l'Inde, aux Moluques et aux Mariannes, passent pour être un produit de la végétation, et se trouver dans l'intérieur de la noix de coco".

FORTHCOMING EVENTS

Monday, November 10

Society of Instrument Technology, North-West Section (at the College of Technology, Manchester), at 7.15 p.m.—Mr. S. S. Carlisle: "An Experimental Electrical Pressure Meter for Measurement of Furnace Roof Differential Pressures".

Tuesday, November 11

Zoological Society of London (at Regent's Park, London, N.W.8), at 5 p.m.—Scientific Papers.

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Sir Edward Salisbury, F.R.S.: "The Vegetation of the Chalk", 3. "Colonisation and Succession; The Flora of Arable Chalk Soils; Chalk Scrub Vegetation".

Institution of Chemical Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. T. A. Hall and Dr. G. G. Haselden: "The Purification of Gases in Low Temperature Processes"; Dr. M. Ruhemann: "The Ammonia Absorption Machine".

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "What Equipment is Necessary for the Servicing and Testing of Electronic Devices?" (to be opened by Wing Commander P. Allerston).

Sheffield Metallurgical Association (at 198 West Street, Sheffield), at 7 p.m.—Mr. J. C. Williamson: "The Metallurgy of Musical Instruments".

Royal Institute of Chemistry, London and South-Eastern Counties Section (joint meeting with the Gravesend Engineering Society, at the Royal Clarendon Hotel, Gravesend), at 7.30 p.m.—Films and Discussion on "Water Treatment" (organised by Mr. S. Stevens).

Wednesday, November 12

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Institute of Petroleum (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Dr. R. N. J. Saal: "Rheological Investigation of Asphaltic Bitumen in connexion with its Technical Applications".

Manchester Statistical Society (at the Reform Club, King Street, Manchester), at 5.30 p.m.—Mr. E. Devons: "Economic Planning".

Thursday, November 13

Physical Society, Acoustics Group (in the Physics Department, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 4 p.m.—Discussion on "Supersonic Absorption in Liquids" (to be opened by Mr. J. M. M. Pinkerton).

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. A. V. Hill, C.H., F.R.S.: "The Resolution of Physical and Chemical Events in Muscular Contraction"; Mr. R. M. Davies: "A Critical Study of the Hopkinson Pressure Bar".

British Glaciological Society (at the Royal Geographical Society, Kensington Gore, London, S.W.7), at 5 p.m.—Mr. H. F. P. Herdman: "The Southern Pack Ice".

Chemical Society (joint meeting with the University Chemical Society, in the Chemistry Lecture Theatre, The University, Sheffield), at 5.30 p.m.—Prof. L. Hunter: "The Hydrogen Bond in Organic Chemistry".

Royal Photographic Society, Scientific and Technical Group (at 16 Prince's Gate, London, S.W.7), at 7 p.m.—Mr. E. W. H. Selwyn: "Photographic Resolving Power of Lenses".

Society of Dyers and Colourists, West Riding Section (at the Great Northern Victoria Hotel, Bradford), at 7.15 p.m.—Dr. A. Landolt: "Hydrophobic Melamine Compounds in Textile Processing".

Chemical Society (joint meeting with the Local Sections of the Royal Institute of Chemistry and the Society of Chemical Industry, at the North British Station Hotel, Edinburgh), at 7.30 p.m.—Dr. Philip Eggleton: "Diffusion in Biological Processes".

Pharmaceutical Society (at 17 Bloomsbury Square, London, W.C.1), at 7.30 p.m.—Dr. Hans Flück: "Chemical and Biological Aspects of the Conservation of Vegetable Drugs".

Textile Institute, Macclesfield, Leek and District Section (joint meeting with the Leek Textile Society, at Nicholson Institute, Leek), at 8 p.m.—Dr. V. G. Jolly: "Abnormal Colour Vision".

Wednesday, November 12—Thursday, November 13

Iron and Steel Institute (at 4 Grosvenor Gardens, London, S.W.1).—Autumn Meeting.

Friday, November 14

Textile Institute (at 16 St. Mary's Parsonage, Manchester), at 1 p.m.—Mr. S. A. Woods: "Colour in Industry with particular reference to Painting Machinery".

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

Chemical Society (joint meeting with the Southampton University College Chemical Society, in the Physics Department, University College, Southampton), at 5 p.m.—Dr. U. R. Evans: "The Corrosion of Metals".

Institution of Mechanical Engineers, Applied Mechanics Group (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Dr. H. E. Rose: "The Mechanical Differential Analyser, its Principles, Development and Applications"; Dr. S. C. Redshaw: "An Electrical Potential Analyser".

Plastics Institute (at the Engineers' Club, Albert Square, Manchester), at 6.45 p.m.—"Injection Moulding of New Thermoplastics".

Institute of Economic Engineering (at the Waldorf Hotel, Aldwych, London, W.C.2), at 7 p.m.—Mr. Wilfred B. D. Brown: "A Proposed Code of Human Management".

Institute of Welding, North London Branch (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Prof. D. Hanson: "Training for Industry".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

States Agricultural Advisory Officer—The States Supervisor, States Office, Guernsey (November 15).

Lecturer in Mathematics—The Principal, Central Technical College, Suffolk Street, Birmingham 1 (November 15).

Research Physicist—The Director, Institute for Industrial Research and Standards, 45 St. Stephen's Green, Dublin (November 15).

Lecturer in Chemistry up to B.Sc. standard—The Principal, Chelsea Polytechnic, Manresa Road, London, S.W.3 (November 15).

Research Fellowship in Rheumatism—The Registrar, The University, Leeds 2 (November 15).

Senior Assistants (2) in the Department of Mechanical Engineering, Lecturers (3) in Mechanical Engineering (Design), and a Lecturer in Mathematics—The Principal, Central Technical College, Suffolk Street, Birmingham 1 (November 15).

Graduate Lecturer in Chemistry and related subjects at the Blackpool Technical College and School of Art—The Chief Education Officer, 3 Caunce Street, Blackpool (November 15).

Teacher of Mining Subjects at the Openshaw Technical School—The Chief Education Officer, Education Offices, Deansgate, Manchester 3 (November 15).

Instructor in Horticulture at the Farm Institute, Merrist Wood, Worplesdon—The Chief Education Officer, County Hall, Kingston, Surrey (November 15).

Assistant Lecturer in Inorganic and Physical Chemistry—The Registrar, University College, Hull (November 17).

Lecturer or Assistant Lecturer in Zoology—The Registrar, King's College, Strand, London, W.C.2 (November 22).

Assistant Lecturer (temporary) in Botany—The Principal, Royal Holloway College, Englefield Green, Surrey (November 23).

Assistant Experimental Officers (temporary, Ref. G.460/47A), and Experimental Officers (temporary, Ref. G.461/47A), in the Department of Agriculture for Scotland, for Inspection, for Insect Infestation, of foodstuffs, warehouses, shops and various storage and food manufacturing premises and associated laboratory work—The Ministry of Labour and National Service, Technical and Scientific Register, Room 669, York House, Kingsway, London, W.C.2, quoting the appropriate Ref. No. (November 24).

Lecturer in Geography—The Registrar, The University, Manchester 13 (November 28).

Lecturer or Assistant Lecturer with special qualifications either in Economic History or in Applied Economics—The Registrar, University College, Hull (November 29).

Physicist to carry out investigations into the structure and physical properties of cellulosic fibres, and a Laboratory Assistant to the Senior Physicist—The Director, British Paper and Board Industry Research Association, St. Winifred's Laboratories, Welcomes Road, Kenley, Surrey (November 30).

Experimental Officer, and an Assistant Experimental Officer, for work in London on insecticides—The Secretary, Agricultural Research Council, 6a Dean's Yard, London, S.W.1 (November 30).

Senior Lecturer in Biochemistry—The Secretary of University Court, The University, Glasgow (November 30).

Lecturer in Engineering at Peterborough Technical College—The Chief Education Officer, Education Offices, Town Hall, Peterborough (November 30).

Meteorological Officer Cadets (10) in the Department of Industry and Commerce—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (December 3).

Lecturer in Physics—The Principal, Royal Technical College, Peel Park, Salford 5.

Laboratory Superintendent by the Government of Nigeria for Medical Department—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.N.18391.

Head of the Engineering Department of the County Technical College, Wednesbury—The Director of Education, Dept. F.E., County Education Offices, Stafford.

Biometrician (Ref. M.N.18186), an Agronomist (Ref. M.N.18175), and a Tobacco Breeding Specialist (Ref. M.N.18181), for the Directorate-General of Agriculture, Government of Iraq—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting the appropriate Ref. No.

Laboratory Steward (temporary, man or woman)—The Principal, Brixton School of Building, Ferndale Road, London, S.W.4.

Laboratory Steward in the Department of Botany, and a Laboratory Steward in the Department of Physiology—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1.

Assistant Technical Secretary (male) by the Ironmaking Division—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1.

Research Assistant in the Pomology Department—The Director, John Innes Horticultural Institution, Merton, London, S.W.19.

Assistant Technician in Chemistry Department—The Secretary, College of the Pharmaceutical Society, 17 Bloomsbury Square, London, W.C.1.

Scientific Assistant for bureau literary work—The Director, Imperial Bureau of Animal Health, New Haw, Weybridge, Surrey.

Lecturer in Mechanical Engineering—The Principal, Erith Technical College, Erith Road, Belvedere, Kent.

CONTROL OF ATOMIC ENERGY

THE second report of the Atomic Energy Commission to the Security Council which was adopted by the Commission on September 11 with only the U.S.S.R. representative voting against it, although the Polish representative abstained, outlines specific proposals dealing with the functions and powers of an international agency for the control of atomic energy. The Commission did not consider that the Soviet Union's proposals of June 11 provided an adequate basis for developing specific proposals for an effective system of international control of atomic energy, and discussions have not led to a reconciliation of the views of the Soviet Union with those of the majority of the Commission on major points of principle. The proposals of this second report are, in fact, based on three principles which were vigorously contested by the representative of the U.S.S.R. These principles are, first, that decisions concerning the production and use of atomic energy should not be left in the hands of nations; secondly, policies concerning the production and use of atomic energy which substantially affect world security should be governed by principles established in the treaty or convention which the agency would be required to carry out; and thirdly, nations must undertake by convention to grant to the agency rights of inspection of any part of their territory, subject to appropriate procedural requirements and limitations.

The proposals of this second report provide for production quotas based on principles and policies specified by convention; ownership by the agency of nuclear fuel and source material; ownership, management and operation by the agency of dangerous facilities; licensing by the agency of non-dangerous facilities to be operated by nations; and inspection by the agency to detect clandestine activities. The specific proposals of this report are believed by the Commission to provide the essential basis for establishing an effective system of control to ensure the use of atomic energy only for peaceful purposes, and to protect States which comply with it against the hazards of violations and evasions. Furthermore, the Commission considers that such questions as the organisation and administration of the agency, the geographical location of dangerous activities and 'stock-piling', prohibitions and enforcements, and the stages of transition to a system of international control, can only be discussed effectively within the framework of conclusions regarding the functions and powers of the international agency.

In arriving at these conclusions, the Commission believes that the establishment of security is the paramount requirement, and the system of control is designed to give the international agency the means of preventing preparation for atomic warfare, as well as to diminish the possibility of one nation or group of nations achieving potential supremacy in the field of atomic energy, to give warning to complying States of any breach of the treaty and to dispel suspicions and false accusations. In choosing between alternative policies, the elimination of national rivalries in the production, distribution and accumulation of nuclear fuels and the determination of overall production-rates are regarded as of outstanding importance to security. At present the science and technique of the production of nuclear fuel are far in advance of its use for peaceful purposes ; nuclear fuels can be produced in quantities which greatly exceed their present possible uses in medicine, research and industry. In stressing this, the report emphasizes that if the right to decide on the number and size of production facilities and on the size of the stocks of source material and nuclear fuel situated on their territory be left to nations, the control measures recommended in the first report of the Commission would not, if applied alone, eliminate the possibility of one nation or group of nations achieving potential, or through seizure, actual, military supremacy.

For this reason the right to take these decisions cannot be left in the hands of individual nations; and accordingly, in this second report, the Commission would charge the international agency with the further duties of implementing the terms of the treaty or convention in respect to the production, distribution and storage of nuclear fuels and the distribution and utilization of dangerous facilities depending on nuclear fuels, as well as supervising mining quotas and the transfer and processing of source material. It is not recommended, however, that the agency should define the policy to be pursued in the production and use of atomic energy. The principles governing this policy should be established by international agreement, and it would be the duty and responsibility of the agency to implement such an agreement. The production of nuclear fuel in a form suitable for ready conversion to weapon use would be kept by the agency at the minimum required for efficient operating procedures necessitated by actual beneficial uses, including research and development. The agency would also be charged with the duty of carrying out the terms of the treaty or convention concerned with the type and location of reactors which fall within the category of dangerous facilities ; and when the technique of the industrial utilization of atomic power has been sufficiently developed, the international agency, within the limit imposed by security, should make that power available on a fair and equitable basis to any nation which may require it.

In regard to research and development, while the agency should have the power to conduct such work, and must have full scientific knowledge of all matters relating to atomic energy, including all innovations as they occur, it is not proposed that private or national research or development work should cease. Such national activities would be limited in scope only in so far as is necessary for reasons of security. Nations or individuals would be forbidden to use nuclear fuel for the manufacture of any atomic weapon, or to use dangerous quantities of nuclear fuel. Since the first report was issued, further study has established the necessity for international control and allocation of the quantities and locations of uranium and thorium which are to be separated, the time and place of the further processing and purification of source materials, and the size, use and disposition of working stocks and stocks in transit. Without such comprehensive international control of the flow of source materials, from the first point where they are capable of being diverted, there would always be a serious risk of the diversion of source material.

The basic policies and provisions governing the exercise of this international control and direction must be specified in the treaty or convention ; ownership of source-material, from the time it is removed from its natural deposit, or from the time other important constituents have been extracted, should be vested in the agency, which would be authorized to lease these materials for authorized uses. The exercise of the right which the international agency must possess, of determining on the spot whether a nation is conducting clandestine preparations for atomic warfare, would be subject to various procedures designed to guarantee nations and individuals against abuse on the part of the agency. These procedures will require consideration from a juridical point of view so that they may be defined in legal terms capable of juridical interpretation.

The rejection by the Soviet Union of the very principles on which these proposals are based, including as they do the prohibition of atomic weapons, makes it difficult to see what further proposals can be advanced with any real hope of unanimous agreement. It is not that there appears to be any ideological obstacle to preclude such agreement : apart from the International Control Commission proposed by the U.S.S.R. last June, so long ago as February 15, 1928, the U.S.S.R. delegation to the League of Nations proposed in a draft Disarmament Convention the adoption of a comprehensive scheme of international inspection. It seems rather that the U.S.S.R. refuses to recognize the logic and inevitability of the conclusions reached by other members of the Commission, and insists on imputing bad faith to all those who do not accept its own views.

Admittedly the atomic bomb put the United States in a powerful position in the military sense, and if competition in atomic weapons should prove unavoidable the United States would have a considerable start which it could almost certainly retain without difficulty. That its desire is otherwise could scarcely be made clearer, and it may well be questioned whether any country could have shown a more striking example of disinterested good faith in the peaceful aspirations of the common man. All atomic energy matters have already been placed by the U.S. Government under civilian control to facilitate the application of atomic energy to peaceful and beneficial purposes. Within its own territory also, all uranium and thorium ores, even those which contain as little as one twentieth of one per cent, have already been placed under the strict control of the American Atomic Energy Commission; and even apart from the threats and accusations of the U.S.S.R., the United States can scarcely be blamed for declining to destroy its stocks of materials before an international authority has been set up with the powers and resources to exercise effective control.

While it may be doubtful whether the U.S.S.R. would accept the point that a convention outlawing the atomic bomb could come into force only when satisfactory controls have been established, the suggestion has not yet been rejected by Mr. Gromyko. Moreover, against the slight gain that the international inspectorate to which the U.S.S.R. has agreed is to be answerable only to the Control Commission, has to be set the unequivocable rejection of the functions of licensing, management and supervision of the dangerous undertakings. Even minor powers of control by the Commission remain subject to the veto in the Security Council, and national acceptance of any recommendations for the carrying out of international rules is to be entirely optional. The questions of secrecy and of the exchange of information are scarcely mentioned in the second report, although their importance is emphasized in the Russian proposals. Without the inclusion of all these safeguards against national misuse of atomic power on which there is widespread agreement outside the U.S.S.R., no form of inspection could be effective.

It is still necessary to continue to explore the possibility of agreement, even though it be with diminishing hopes. The two primary questions that are now emerging, however, are whether at the present time it would not be wiser to postpone consideration of the control of large-scale power production and forgo the use of atomic power until the world is better prepared for it; and whether the development of an atomic energy authority among those nations which are prepared to accept the essential limitations of sovereignty should proceed. The first question has been pressed by two of the scientific workers who worked in the Oak Ridge gaseous diffusion plant, Mr. Cuthbert Daniel and Mr. A. M. Squires, who have suggested that for the present not even the atomic development authority should either mine or process fissionable materials or operate reaction piles which would yield significant quantities of nuclear fuel, and that production of weapons and further weapon research should be stopped. With the setting up of international inspection, the authority would take over all existing plans and stocks together with the 'secret', and it would also arrange for an approved allotment throughout the world of all the fissionable materials required for other purposes, but would destroy all surpluses and dismantle the plants.

Such a plan bids high for Russian agreement, and might secure it; but the vital question here is not whether the advantages to be gained from the industrial use of atomic power are worth the risks of the bomb which they incur. It is not simply a question of whether it is worth taking an avoidable risk for the sake of what might be gained at the power stations in the next twenty years. The question is rather, is the risk avoidable? To put it bluntly, could the United Nations trust Russian adherence to such an undertaking in the absence of such an inspection system as is proposed by the Atomic Energy Commission itself?

If we cannot give ourselves a satisfactory answer to that question of good faith—and recent developments make that increasingly probable—we are left with the security issue paramount, and the question becomes whether we should go forward without the U.S.S.R. with the development of an atomic energy authority. There can be no doubt as to the dangers and difficulties of such a course, but equally we should not overlook the value of a practical demonstration of the possibility of an international system even within a limited field. If the United States, Great Britain and a number of other like-minded States could demonstrate to the world that the essential sacrifices of national sovereignty were, in fact, being made, and that the system was working satisfactorily, the all-important first step would have been taken and nations at present inclined to stand aloof might come in. But participation now or at a future date presupposes just that goodwill, that confidence and mutual respect which the U.S.S.R. is disposed to deny to those who are unwilling to be over-ruled by her authority. Whether even in the field of science those relations of trust and understanding can be established, in the face of restrictions on movement and such restraints on communication of scientific and technical information as those of the new Russian law on disclosure of State secrets, may be doubtful. It seems clear, however, that in this field of atomic energy, as in wider fields of science, the scientific worker can only seek to move forward on the line that the discipline and tradition of science have taught, avoiding so far as possible all that could exacerbate feelings or confuse the issue, testing each hypothesis and trying out the most promising in a limited field if necessary, and extending the experiment as the results indicate and opportunity offers.

THE DEVELOPMENT OF BRITISH CHEMISTRY

The Chemical Society, 1841–1941

A Historical Review. By Tom Sidney Moore and James Charles Philip. Pp. 236+10 plates. (London: Chemical Society, 1947.) 12*s.* 6*d.*

British Chemists

Edited by Alexander Findlay and William Hobson Mills. Pp. 432+16 plates. (London: Chemical Society, 1947.) 18*s.*

FOUNDED in 1841, the Chemical Society was the first nation-wide organisation concerned exclusively with "the advancement of chemistry and those branches of science immediately concerned with it". It led the way to the foundation of similar societies in France (1857), Germany (1867), and the United States (1876). Among permanent records of the recent centenary celebrations, the Society has issued these two appropriate volumes. They abound in material of abiding interest to all lovers of chemistry, and are truly worthy of the historic occasion.

The first volume traces in detail the foundation and growth of the Society. It is a story of modest beginnings, of growing pains, and of many later vicissitudes; but the curve of progress ascends steadily with the passage of time. Of willing and devoted members and officers there has never been a lack in this Society.

The tasks have passed from hand to hand, from generation to generation; but they have always been fulfilled.

As we read, the story grows into one of expanding activities and increasing complexities of organisation and administration, brought about by the astonishingly rapid development of chemistry and of the chemical profession in Great Britain. When one considers the handicaps under which the Society has laboured, its accomplishments appear all the more remarkable. The greatest handicap of all has been for many years the lack of housing accommodation. "The Meeting Room . . . is filled to suffocation at discussions and can seldom be used for lectures . . . after a century of public-spirited activity the Society is housed in premises which in no single respect are even tolerably adequate for its nationally important work." The Society provides the main channel in Britain for the publication of research in pure chemistry, and houses a national chemical library; yet, to take one problem alone, it is called upon to operate in these confined quarters "a library of 44,000 volumes growing at the rate of about 1,000 volumes a year, to the use of which 15,000 individuals are entitled".

The narrative, which is embellished with ten illustrations of much historic value, throws light upon the foundation of other organisations of chemical interest, such as the Institute of Chemistry, the Society of Chemical Industry, and the Association of British Chemical Manufacturers. To a large extent these and still other organisations may be regarded as offshoots of the Chemical Society, and it is a satisfactory feature that a growing co-operation has taken place in recent years between the numerous British societies owing an ultimate allegiance to chemistry. It is to be hoped that this tendency, which means so much for British chemistry, may lead ultimately to the realization of Pope's ideal of a 'Chemistry House' to accommodate all the chemical organisations, thereby releasing the Chemical Society from its cramped quarters in Burlington House, London.

Although the first of the volumes under notice deals primarily with the organisation and growth of the Society, it throws many interesting sidelights upon past presidents and others who have been closely concerned with that organisation and growth. It is illuminating, for example, to find Liebig writing of England as "the country which I love like my own Fatherland"; and to discover Victor Meyer sitting between Roscoe and Hugo Müller at the jubilee dinner of the Society (1891) and talking of "Kekulé, as, buried in thought, he rode home on the top of an omnibus through the streets of this great metropolis, after spending an inspiring evening with my neighbour on my left, his friend Dr. Hugo Müller". Those were truly days of internationalism in chemistry.

In these pages, too, we encounter the doughty H. E. Armstrong, the 'grand old man' of British chemistry; Vernon Harcourt, whose "long sentences were as precious to him as to Henry James; but he swayed them with equal skill and we would sigh with relief when the soothing and beautifully modulated voice emerged successfully from a seemingly hopeless tangle"; Tilden, with "that shade of dignity which has now become old-fashioned but remains precious"; Philip, the range and quality of whose personal services is probably the greatest in the history of the Society; Meldola, who traced his descent through sixteen generations back to Israel Meldola, born at Toledo in 1282; Ramsay, P. F. Frankland, W. H. Perkin, jun., Pope, Morgan, Greenaway, the courtly and upright G. G. Henderson, and many another. Here is a richly variegated human tapestry.

The main theme of the first volume is the development of the Chemical Society. Happily, however, as just indicated, the account includes also numerous short personal sketches of eminent British chemists who have served the Society in their day and generation. This is a particularly valuable feature to the humanist in chemistry; for the second volume, which is complementary in scope, deals solely with the personalities and researches of a strictly limited number of British chemists of this period. Naturally, in a volume of this size, it is impracticable to give full-length studies of more than a select few of the outstanding figures. These range in chronological order from Crookes, who was a boy of nine when the Society was founded, to Barger, born in 1878.

Here we find worthy biographical sketches of sixteen British masters who have died since the outbreak of the First World War. Some of these memoirs have been specially contributed by writers with first-hand knowledge; others are reprinted or adapted from existing memoirs. The volume, which has been skilfully edited, contains an account of the life and work of each subject, together with a portrait. It fills a gap in biographical chemistry which has persisted for too long; for although the Chemical Society has published several volumes of memorial lectures of much dignity and charm, dealing with distinguished foreign chemists, it has been unduly modest in this respect about its own members. Now that the ice has been so admirably broken, the hope may be entertained that future volumes of a similar kind will be forthcoming in due season. These might perhaps to some extent be retrospective, so as to include not only British masters of the future, but also some more of the chemical past masters of the British Commonwealth of Nations—such as Purdie, in Scotland, Orme Masson and H. G. Smith, in Australia, and P. C. Rây, in India—for whom space could not be found in this inauguratory volume.

In conclusion, it is pleasing to note that the cost of these two volumes has been generously defrayed by the printers, Messrs. Richard Clay and Company, Ltd., who have done so much yeoman work for the Society, as a contribution to the centenary fund. Together, the two volumes form a contribution of such high interest and value that they will inevitably find a place upon the bookshelves of all who have a lively interest in chemistry. JOHN READ

VEGETABLES OF HONG KONG

Vegetable Cultivation in Hong Kong

By G. A. C. Herklots. Pp. iv+208. (Hong Kong: South China Morning Post, Ltd., 1947.) 12 dollars.

BOOKS on gardening are many and varied, but few volumes can have made a more dramatic entry to a localized horticultural community. Born during the incipient siege of Hong Kong and nourished during a forty-three months 'sojourn' in the Stanley Civilian Internment Camp, the book holds the attention of even a Western reader. It must have a far greater significance in the region for which it is particularly written. The volume describes about a hundred kinds of vegetables, giving cultural details, discussing varieties, recipes and food values. Chinese names and ideographs appear in the text, and most species are illustrated by very clear but artistic line drawings. Woven through these foundation strands, however, is a very modern exposition of horticultural science. This is, of course, particularly adapted to Chinese conditions; but is a graceful blend of simple, age-old methods with modern scientific achievement. One learns how to compost organic matter with human urine and also the use of D.D.T. for pest control. 'Canton mud' settling from ponds where fish are fed on human excrement still provides a source of garden fertility, and yet weeds are now controlled by 2:4 dichloro-phenoxyacetic acid.

Horticulture in Hong Kong brings its own special problems. Seeds must, in general, be kept dry until planted, being packed in lead envelopes, and even stored in a desiccator. Periods of dormancy and of seed life are very short; parsnips and rhubarb provide good examples, while *Hippeastrum* seeds should be sown within a day or two of dehiscence from the capsule. New Zealand spinach seeds, on the other hand, germinate more vigorously after a year's storage. Hong Kong soils vary from porous lateric sand to an impermeable clay, but all are poor in major plant nutrients and most are too acid for good growth of vegetables. Several pages are accordingly devoted to the improvement of the physical and chemical nature of the soil. Temperature limits the growth of some plants, as the English cabbage, to the winter in Hong Kong, but tropical warmth from May until September permits the growth of many plants from the torrid zone. Periods of high humidity in March and April provide good conditions for the spread of fungal diseases in those months. The relatively short day makes it impossible to grow European varieties of onions for bulb formation. Seed potatoes from England do not grow well in Hong Kong, but several short-day potatoes from the Empire collection at Cambridge have been flown there and are now under trial. Other adaptations to special conditions are discussed in this book.

Many English friends of Dr. Herklots will value this publication, not only for its scientific and horticultural worth, but also as marking a vigorous return from the trials of internment. It seems possible to read between the lines, to imagine the difficulties at Stanley camp, and to admire the persistence which produced this most useful book. It would have been a credit to a similar study made in freedom.

John Grainger

AMERICAN METHODS AND PRACTICE IN AIR SURVEY

Manual of Photogrammetry

Edited by P. G. McCurdy, L. A. Woodward, J. I. Davidson, R. M. Wilson and R. E. Ask. Pp. ix+819. (New York, Chicago and London: Sir Isaac Pitman and Sons, Ltd., 1944.) 45*s.* net.

THIS manual has been produced by the American Society of Photogrammetry, some sections having been previously published in *Photogrammetric Engineering*, the journal of the Society. The Society is a very active one, and its journal regularly provides valuable technical information. Its membership extends overseas, including some from Great Britain.

The manual is composed of contributions by some thirty eminent members, together with sections from official and commercial sources. It has been edited by a small committee and presents an up-to-date picture of aerial photogrammetry with reference to American practice.

The range of subject-matter is wide: from the principles of surveying, optics, photography, perspective, and stereoscopy, to the basis and practical application of graphical, analytical and instrumental methods of mapping from air photographs. The chapters in themselves are self-contained.

One of note is that on mapping from obliques, which is dealt with in some detail. Practice in Canada, where considerable areas have been covered by obliques for reconnaissance mapping, is described, as is that developed by the American Geographical Society, with particular reference to exploratory surveys. Most important, however, is the section on trimetrogon mapping, in which three wide-angle cameras are used—one vertical and two lateral high-obliques—so that a lateral strip is covered from horizon to horizon by each set of exposures. By use of primary trigonometrical control, or independent astro-fixes, a rapid and effective method is available of reconnaissance mapping at scales of 1/250,000 or 1/500,000. Many hundreds of thousands of square miles were mapped by the U.S. Army Air Forces during the recent War in connexion with the charting of air routes over undeveloped country.

Another important chapter is that on radial line plotting, where, in addition to the usual graphical method, descriptions are given of its 'mechanization', by slotted templates or by mechanical radial arms.

The chapter on American survey cameras, mostly of Fairchild manufacture, is in the nature of a catalogue. No foreign types are described.

The manual is a mine of information on practical detail, evolved as a result of lengthy experience in the methods described; but it suffers inevitably from its preparation by a large number of contributors. Some aspects are omitted altogether, others sketchily treated from a scientific point of view, while there is some overlapping between the chapters, due to different authorship and separate publication.

It can by no means be considered a text-book of the subject, since no attempt is made to present a balanced and logically developed treatment. It is surprising, for example, to find that there is no reference to precise three-dimensional instruments such as those of Wild, Zeiss and Poivilliers, or of British designs, since instruments of this class are now recognized as having important applications in air survey. Also the title should be more properly "Manual of Aerial Photogrammetry", since there is no reference to ground photogrammetry. The edition is, however, a provisional one, so it is to be expected that some of these anomalies will be omitted in subsequent editions.

The final chapter on nomenclature and definitions is particularly welcome, and although some of the terms are at variance with British practice, it is to be hoped that it will not be impossible in the future to standardize.

The manual will prove a valuable reference work to air surveyors so long as it is recognized that it refers to American methods and instruments only. There is little critical comparison between the various American instruments and methods, some of which have been described by those commercially interested in them. Neither is there any description of, or comparison with, methods and instruments used extensively outside the United States, in the British Empire and elsewhere.

C. A. Hart

OPERATIONAL RESEARCH IN WAR AND PEACE

A DISCUSSION on operational research in war and peace was held by the Division of the Social and International Relations of Science of the British Association, during the Dundee meeting of the Association. The chair was taken by Dr. C. H. Desch and the discussion opened by Sir Robert Watson-Watt. Other speakers included Dr. O. H. Wansbrough-Jones, Prof. S. Zuckerman, Prof. W. C. Wilson, Prof. F. A. E. Crew, Mr. L. Moss and Prof. J. D. Bernal.

Sir Robert Watson-Watt said he believed that responsibility for the term 'operational research' rested with himself. He had no recollection of any positive definition, which did not emerge until late in the work, although it contained something of "doing arithmetic for Air Staff", market and consumer research, and the less naively offensive elements of motion study. Neither did he recognize the description of operational research by the president of the British Association, Sir Henry Dale, as that "which estimated destructive effects and planned destructive policy". If terms of reference were needed, he would suggest these, for industry as well as in war :

"To examine quantitatively whether the user organisation is getting from the operation of its equipment the best attainable contribution to its overall objective, what are the predominant factors governing the results attained, what changes in equipment or method can be reasonably expected to improve these results at a minimal cost in effort and time, and the degree to which variations in the tactical objectives are likely to contribute to a more economical and timely attainment of the overall strategic objective."

Operational research, Sir Robert proceeded, is beginning to look very like real scientific management, and he believes that it is an important contribution to the still unsolved problem of the relationship between the administrator and the expert. The essence of that licensed busybody, the operational researcher, is that he has learnt about things and about people; that he "lisps in numbers, for the numbers come", and that he is believed by the individual user of technical equipment because he and his like have been shown capable of ensuring great improvements in the performance of the equipment and in the comfort, security and self-fulfilment of the user. In war, the pioneer practice in the R.A.F. might be described as having been centrifugal, certainly as highly devolutionary, and the naval counterpart was by contrast highly centralized. In peace, Sir Henry Dale had a right to ask whether "we can accept as directly obvious the suggestion that Operational Research . . . would qualify for guidance in the immeasurably more complicated and fundamentally different problems of reconstruction". It would be disastrous if this legitimate query were misread and misapplied as a positive statement of rejection. Sir Robert doubted whether the peace ensemble is, in fact, more complex than the war ensemble, nor could he perceive any fundamental difference between the problems within a peace-time industry and those on one side of the gulf of war. The argument, he considered, was "desperately important" and he said he meant every syllable and stress of those words.

In conclusion, it was with profound regret that he had heard Sir Henry Dale speak of the "conscription of science". All that was asked by those who believed in the present application of operational research, and felt that "the rocks might crumble beneath the ivory city", was that they "be given the academic freedom of operational research to measure the facts, the dangers and the towering possibilities".

Dr. O. H. Wansbrough-Jones, speaking of Army applications, stated that the method should have improved on that recommended by Newton for navigational technique by the introduction of better statistical and other scientific tools ; and on current methods of administrative planning in the Army by giving greater freedom both in opportunities of direct observation and of freedom from daily routine. Also, although successes might rightly be claimed by those who did the work, their scientific training and objective approach would have been insufficient if there had not been a readiness, especially at high levels, to receive, absorb and encourage these scientific men and to heed their results ; if there had not been a few outstanding men of science to lead the work, as well as a sufficient body with a good knowledge of the ways, tasks, and difficulties of the Army ; and, pervading it all, the intense stimulus of national need. Unless each condition was met, at least in part, this type of work would not be useful.

Home sections were formed during the War to study tank gunnery, field artillery and infantry weapons, and the process culminated in the provision of a further six sections to work in theatres of operations. Up to the end of 1945, some 365 scientific workers were employed in operational research on behalf of the army, the maximum number employed at any one time being about 174. Up to date, they had produced some 380 reports of varying importance roughly equivalent in size to the average scientific paper, and nearly 600 memoranda of smaller importance, besides dealing with a very large number of day-to-day queries. Those at home had worked under the Ministry of Supply, and the overseas sections under indirect War Office control. The present scientific force is very much reduced, and the division between the Ministry of Supply and the War Office still remains, but the relationship is very close and likely to become closer.

Taking two overseas sections as examples, that with 21st Army Group had a maximum strength of twelve. It was in the theatre of operations from D-Day until July 1945, and produced some forty reports covering a variety of subjects most of which had been suggested by the investigators themselves. Those first selected, after a few weeks of initial study, were the location of enemy mortars, the distribution of hits and penetrations in our own and the enemy's tank casualties, the performance and best method of use of the PIAT, the problem of dust on roads and airstrips, and the examination of mud. Of these, that on dust was taken over by the Air Force, that on mud proved too valuable, and the PIAT work was mainly technical ; but the mortar location and tank casualty work was completed with good results. The report on the first was the factual basis of the counter-mortar organisation later set up with 21st Army Group : that on the second provided accurate data on how armour should be distributed on tanks fighting in close country. Work was also continued on the two basic problems of air and artillery bombardment, and events led the operational researchers back to them. Among the results was the first objective assessment of the effects achieved by a given weight of bombing in support of ground troops.

The corresponding section with the 14th Army in Burma determined maintenance tonnages and man-power wastage. In the event, the application of these two studies to the planned assault on Malaya and Singapore remained untested. As to the need in such work for highly trained scientific workers, Dr. Wansbrough-Jones suggested that, although operational research probably did not demand such training, it was greatly helped by scientific training. "It is much more", he stated, "than the straightforward collection of facts and the writing of histories; it must continually seek out new sources of information, especially the least obvious, and by sound reasoning from the facts, provide a new understanding of its particular problem." In peace the emphasis falls naturally on training and administration, and it is hoped to study, in particular, the adequacy of the existing motive of Army service, means for increasing its value, and the effectiveness of substitute motives such as group or individual rewards, the acquisition of knowledge and skills, and the use made of synthetic trainers of various types.

Dr. Wansbrough-Jones believes that for some young scientific men, those really interested in the social applications of science, diversion for a time to operational research, but not for too long, would be not only justifiable but desirable. With adequate safeguards, and good career control, it would be an advantage to many to work for a year or so, say in their late twenties, for a Government department; to leave industrial laboratories to work on the scientific man-power sides of their industries, and defence laboratories to work with the Services. Army plans for the last are being put into force.

Prof. S. Zuckerman distinguished between operational research at the technical, tactical and strategic levels. At the first level was an investigation of the manner in which bombs cause casualties, and it was at this level that the better part of the scientific man-power engaged with the Fighting Services during the War was employed. Operational research into different kinds of tactics and methods of organisation consumed the bulk of the remaining effort. One example was the relationship between different types of formation-flying and accuracy of bombing. Scientific men, with their understanding of the techniques involved, appreciation of the tactical problems to be overcome, and emphasis on objectivity and statistical method, can arrive at solutions about tactics which could have been derived only accidentally by other methods. Scientific intervention at the level where major strategic policy is determined was slight—although it would have been impossible for the Ministries of Food and Home Security, for example, to take reasonable decisions on policy without the constant help of expert knowledge, fortified in one case by nutritional surveys and in the other by a large organisation working experimentally and in the field. On the military plane, however, most major operational policy was determined without recourse to scientific advice, and examples of scientific intervention are thus few. Lord Cherwell, as Paymaster-General and scientific adviser to the Prime Minister, was no doubt able to bring scientific method to bear on decisions affecting major policy. In addition, two specific examples were quoted. In the anti-U-boat campaign, scientific analysis not only helped to determine the convoy system, but also assisted in showing the value of diverting four-engined bomber aircraft to U-boat patrols. The second concerned the strategic policy underlying the employment of heavy bombers against the enemy. Objective and quantitative analysis showed that the bomber offensive against German industrial cities was not depressing the level of German production to the extent hoped for, but that attacks against communications would have a far-reaching and immediate effect. Revision of strategic policy in the spring of 1944 was based on this objective appreciation, which was confirmed by subsequent examination in Germany.

What was true about the value of scientific method during the War is no less true to-day, Prof. Zuckerman proceeded. War is not a state of unfettered individual enterprise, any more than unfettered individual enterprise could be the characteristic of the present economic and political state of Britain or Western Europe as a whole. The Government has added to the normal function of administration executive duties which make it necessary either that officials should lean more and more upon scientific advice or become more and more scientific themselves. Cabinet planning bodies such as that presided over by Sir Guy Plowden, and the Advisory Council on Scientific Policy presided over by Sir Henry Tizard, may be regarded as operational research sections established at a strategic level in the economic field. As the situation develops, the function of such different bodies may find a common meeting-ground for the exposition of the major economic, scientific and administrative problems which have to be taken into consideration in a fruitful peace-time strategy.

Prof. W. C. Wilson described the work of No. 1 Medical Research Section in the Middle East between May 1942 and April 1943. Its mandate covered all matters concerning the welfare of fighting men in a very large territory with several distinct and varied climates. The reports of Dr. A. L. Chute, a Canadian physician and physiologist, gave extensive factual data on wounds, evacuation of wounded, fatigue, effects of stress, hours of sleep, food, appetite, cooking and other aspects of tank fighting. Dr. E. T. C. Spooner, a Cambridge bacteriologist, undertook a general survey of Middle East conditions, and studied the typhus situation in Egypt, desert sores, and the outbreak of infective hepatitis of late 1942. Prof. Wilson's own work was on the problems of burns and 'wound shock'. Points which stood out in retrospect were the value of a section composed of independent, full-time and fully mobile observers; and the conclusion that minority opinions should not be ignored, even when counter to expected results. The shortage of trained medical investigators had proved a handicap, and Prof. Wilson was not optimistic that it could be easily or quickly remedied. But if the latent forces of interest and idealism in the medical profession could be mobilized, they might provide a research weapon of immense power in new fields such as social medicine.

Prof. F. A. E. Crew discerned two phases in the application of scientific research in a protracted war: the first in which the production of machines and materialities were the essential preoccupation, and the second in which these were gradually overtopped by problems of the health, morale and efficiency of men. It had been expected that the Army Council would refer to the Medical Research Council any problem of urgency and military importance which fell into the sphere of the biological sciences; but this arrangement did not work, and Sir Edward Mellanby had ultimately created a field investigational organisation which provided the model, so far as he knew, for what was later done by the Army itself. Lessons for the future were that the nature, and even the existence, of a problem of quite serious importance could remain unrecognized until investigated by selected and highly trained scientific workers; that mixed teams are required, of compositions determined by the probable nature of the problem; that hopeful investigation depends on willingness on the part of the community to participate actively; that results, however potentially valuable, can remain disregarded until thoroughly appreciated at the topmost levels; and that for rapid solutions, simultaneous investigation in different circumstances by different teams is a very great advantage. The only danger is that, with the return of peace, the Medical Research Council might find it necessary to withdraw from social biology.

Mr. Louis Moss, director of the Government Social Survey, referred to the need for studies of both the social and industrial conditions of particular jobs, as well as of the attitudes of potential recruits, if labour were to be induced rather than compelled to particular industries.

Prof. J. D. Bernal, as the last speaker, was handicapped by the length of discussion which had already taken place, and what follows is based on the written contribution which he had intended to make. The same needs, he contended, that led to the appearance of operational research in war should now lead to the conversion of that experience to peaceful uses, since the gap between imports and exports and the impossibility of Britain feeding itself are at least as serious and immediate as any war situation. 'Operation Production' should be considered with the same urgency and common purpose as 'Operation Overlord'. The technique of operational research could be made available to find out what has to be done, to check the success of the operation and modify its conduct. It is essential that the country's very limited resources in trained man-power in engineering and science should be used in the most effective way with a scientifically determined system of priorities, weighing not only present resources, but also those which could be increased, often by very large factors, by the application of high-pressure research and development. Only a combination of economists, engineers and scientists could achieve this; but they must operate on the highest planning authority in the country. The most obvious priorities are coal, steel, building and agriculture; but others such as transport, distribution and the utilization of chemical wastes may prove equally important. Prof. Blackett's general principle of operational research should be used, to do those things which combine the greatest need with the most rapid possibility of achievement.

All these are in the nature of economic planning, but physical research is required wherever materials and techniques have to be transferred from their present use to some new one. Lively and effective research would also be necessary on the workshop and farm level, and all the ingenuity in the country would be needed to solve the thousand small problems that would arise. Thousands of scientific workers and engineers are being used in a wasteful manner or for purposes of secondary importance—a very large number in industry and probably as many in Service research. Operational research is needed to find the best distribution and to check redistribution. It would be tragic, he concluded, if this one organisational development of the War were not given the chance to show its capacity in the peace.

THE INSTITUTE OF SEAWEED RESEARCH

"HERE, Scotland has a chance. Eire, Norway, America, Japan, have all, in varying ways, exploited their seaweed resources. We are only at the beginning, and this splendid research station gives us the opportunity not only of making up on these countries, but of surpassing them." So declared the Right Hon. Joseph Westwood, Secretary of State for Scotland, when, on September 19, he officially opened the headquarters of the Scottish Seaweed Research Association—the Institute of Seaweed Research, Inveresk Gate, Musselburgh, Midlothian. Until recently a large mansion house, Inveresk Gate now contains adequate botanical, chemical, engineering and photographic laboratories, engineering workshops, a drawing office, a library, and conference and display rooms, apart from the necessary offices. The Institute stands in eleven acres of ground, and is situated sufficiently near Edinburgh, the University, and the sea to meet the Association's various needs.

The Association was formed in June 1944, and until Inveresk Gate became available the director and staff used the King's Buildings (of the University of Edinburgh) A.R.P. Control Centre as offices, as well as certain of the University's research laboratories and facilities. During the first two years of its life the Association was financed by means of a grant of £25,000 from the Development Fund. Thus was made possible a survey of Scottish seaweed resources and investigations into methods of harvesting, handling and processing these resources. Now, Government has provided over a period of five years a further sum of £90,000, and it is hoped that at least another £10,000 will be forthcoming from industry, and from public-spirited individuals.

Dr. F. N. Woodward is director of the Institute, but at the moment has been seconded to act as director of the United Kingdom Scientific Mission in the British Commonwealth Scientific Office in Washington. The acting director is Major P. Jackson. Under this joint direction the staff of the Institute operates under three divisions: botanical, chemical and engineering. The activities of these divisions may be outlined, as in the director's report, as follows:

(1) *Survey of Scottish seaweed resources.* (*a*) Development of reliable survey methods. (*b*) Quantitative survey of the Scottish coast for littoral, sublittoral and cast brown weeds. (*c*) Study of economic and ecological factors. (*d*) Determination of optimum conditions of growth by controlled culture.

(2) *Harvesting and processing investigations.* (*a*) Development of economic harvesting methods. (*b*) Determination of optimum conditions of drying, grinding and processing.

(3) *New and extended uses of seaweed and seaweed products.* (*a*) Determination of the chemical composition of Scottish seaweeds and its variation with change of species, season, age, environment, etc. (*b*) Determination of the properties and characteristics of the chemical components of seaweed and their derivatives, with the view of finding new and extended uses. (*c*) Development of methods of production of such constituents and their derivatives as are of potential technical value. (*d*) Determination of the value of seaweed as a component of animal feeding-stuffs and as a fertilizer.

Superimposed upon this programme, and as a logical outcome of its partial completion, is the new problem which arose during 1946, that of endeavouring to establish in the Outer Hebrides a ground, dried, rockweed producing unit.

At this stage it may not be out of place to outline briefly the activities of the three Divisions. Acting head of the Botanical Division is Mr. F. T. Walker. He and his assistant algologists have had to solve one of the two main problems facing the Association, namely, whether or not there is enough weed on Scottish coasts at a density sufficient to warrant commercial utilization. Accordingly, a littoral weed survey was commenced in April 1945 and concluded in December 1946. During this time, 4,250 of the 4,630 miles (92 per cent) of practical Scottish coast, exclusive of the Shetlands, were covered and more than 180,000 tons of littoral weed estimated to be present. The most prolific area apparently is in North Uist, where Loch Maddy and Loch Eport support a total of about 60,000 tons of littoral weed. On the basis of this estimation and full-scale trials now nearing completion it may be feasible to establish a harvesting and processing unit in Loch Maddy. One of the most prolific areas for sub-littoral weed is likely to be found around the Orkney Islands, where the sea-bed between one and six fathoms (low water) has been estimated to support well over 1,000,000 tons, perhaps nearly 2,000,000 tons, of seaweed of the family Laminariaceæ. The species of this family most common to the Scottish coast do not apparently grow in measurable quantities below nine fathoms (low water), and to harvest at depths below six fathoms (low water) would be quite uneconomic. A further survey of the sub-littoral seaweed growth around the Orkney Islands, and, if possible, of other rich algæ-bearing areas in Scottish waters, is part of the programme of the algologists for 1947–48, using techniques developed in the Association's laboratories. Other aspects of their researches include a survey of the cast seaweed during the winter months of 1947–48, a determination of the rates of regrowth and recolonization of the Fucaceæ of Orkney, an estimation by controlled cultural methods of the minimum requirements for successful growth and development of the British Laminariaceæ from zoospore stages, and the induction of polyploidy in the Laminariaceæ by chemical and physical means. Moreover, several extra-mural investigations are in progress. Dr. Delf and Miss Moss of Westfield College, London, are studying the concentration gradients and constitutional and physiological differences in the Fuci from areas of varying exposure, and Prof. Bennet-Clark and Mrs. Milnthorpe, of King's College, London, the metabolism of respiration of the Laminariaceæ.

Meantime, one can say with safety that the Botanical Division has shown that sufficient seaweed is available in Scotland to make the seaweed industry a commercial proposition, *if the seaweed can be harvested.*

The harvesting of the seaweed is, of course, the second of the two main tasks confronting the Association, which stands or falls by its ability to solve the problem. This is the problem of the Engineering Division headed by the deputy director of the Institute, with Mr. Wm. Mackenzie, who has been with the Association since its inception, as second in command. Seaweed growing in the littoral zones is comparatively easy to harvest; and methods of harvesting have already been devised and are being developed. Sub-littoral seaweed, growing on the rocky sea-bottom at depths of between one and seven fathoms (low water), is much more difficult to harvest. In most parts of the Scottish coastline it grows fairly close inshore and necessitates the use of powerfully engined, shallow draft, and easily manœuvrable vessels. Therefore, before embarking on a costly series of experimental investigations, the Engineering Division has contacted upwards of thirty engineers and interested members of other professions in the universities and colleges, Government departments, Government and other research organisations and in industry with the view of obtaining as many suggestions and constructive criticisms of existing ideas as possible. As a result, the problem has been considerably clarified, and now six possible methods have been evolved which are considered worthy of full-scale investigation. Already the first two experimental units, operating on different principles, have been designed and all the necessary equipment ordered, and shortly the first trials will start off the west coast of Scotland. Meantime, during much of the past year the engineers have had to devote themselves to matters associated with the lay-out, furnishing, servicing, equipping and the adaptation of Inveresk Gate to the Association's needs.

Assuming, then, that the necessary apparatus for the harvesting of the sub-littoral seaweed will be evolved, the main object of the Scottish Seaweed Research Association will be the development of seaweed as a source of chemicals. So far, the only seaweed product that is being used commercially on a large scale is alginic acid; but for every ton of this acid which is extracted, there are three tons of potentially useful chemicals running to waste. Obviously, the Chemical Division, headed by Dr. W. A. P. Black, has a huge field for research, and many problems have been initiated. Several of these are extra-mural investigations at certain universities and research establishments, either on a contractual or on a collaborative basis. Dr. Percival, at the University of Edinburgh, has developed accurate methods for the estimation of alginic acid, laminarin and mannitol, and is also directing research on fucoidin. At the University of Manchester, under the direction of Prof. E. L. Hirst, the chemistry of alginic acid and laminarin was being investigated. Perhaps this work will now also be conducted in Edinburgh, in view of Prof. Hirst's recent appointment to the new Forbes chair of organic chemistry in this University. At the Imperial College of Science and Technology, Sir Ian Heilbron and his colleagues Dr. L. N. Owen and Dr. A. H. Cook are studying the brown seaweed lipoids and the chemistry of the algal reproductive processes. Algal sterols are being studied at King's College, London, by Prof. D. H. Hey; while at University College, Nottingham, Dr. D. O. Jordan with the late Prof. J. Masson Gulland was attempting to isolate and identify the unknown constituents of the brown seaweeds by electrophoretic methods.

During the past two years the staff of the Chemistry Division has been working on the seasonal variation in the composition of some common brown algæ. For example, in 1946, some 144 samples of littoral weeds of the family Fucaceæ, *Pelvetia canaliculata*, *Fucus spiralis*, *F. serratus*, *F. vesiculosus* and *Ascophyllum nodosum*, and of sub-littoral weeds of the family Laminariaceæ, *Laminaria digitata*, *L. saccharina* and *L. Cloustoni*, have been collected and prepared under strictly controlled conditions, and their dry weight, ash, iodine, nitrogen, mannitol and alginic acid contents determined. It is of interest to note that the results recorded for 1946 are comparable with those obtained for 1945; indicating that the results may be approximately reproducible in subsequent seasons.

Another problem of much scientific and technical importance is a study of the variation in the composition of the sub-littoral seaweeds with depth of immersion. So far, the results obtained substantiate the hypothesis that, consequent upon depth of immersion, there is a decrease in light intensity affecting the photosynthetic processes, which is reflected in the composition of the weeds.

The above programmes of research and development have been approved by the Board of Management under the chairmanship of Sir Steven Bilsland, who is also chairman of the Scottish Council (Development and Industry), as well as by the three specialist Advisory Committees, Algological, Chemical and Engineering. At the official opening of the Institute, Sir Steven emphasized that Scottish seaweed could provide an industry worth £15,000,000 per annum. Of this sum one third would go to collectors. In all, 90 per cent would be spent in Scotland and only 10 per cent outside Scotland.

Thus, for the first time, there has been sponsored in Great Britain an organisation set up to develop an industry based on waste, indigenous, natural products. It is interesting and suggestive to recall that it is now more than sixty years ago (1884) since Stanford, employed in the Scotch kelp industry, first discovered algin and some of the substances contained therein—calcium, magnesium and sodium in combination with the new alginic acid.

H. R. FLETCHER

MECHANISM OF COLOUR VISION

ALTHOUGH some references were made to visual investigations carried out for the Forces during the War, the International Conference on Colour Vision held at Cambridge during July 28–August 2 was concerned mainly with the fundamental problem of how the visual mechanism works and, in particular, with the apparatus by which differences of colour are perceived.

R. Granit (Stockholm) reviewed the outstanding new development in this field, the work which he and his school have carried out on the electrical response of single fibres of the optic nerves of experimental animals such as the frog, cat, snake, etc. The response is picked up by applying a micro-electrode to the retina of an eye from which cornea and lens have been removed. Potential spikes generated between the micro-electrode and a second electrode, placed usually at the back of the bulb, may occur only on illuminating the retina (pure on-elements), or only on cutting-off the illumination (pure off-elements), or after both these operations (on-off-elements). But in every case a spectral sensitivity curve for the element which the micro-electrode has contacted can be measured by finding the smallest energy of various wave-lengths which just suffices to elicit a minimal characteristic response. Certain signs, for example, a single spike response at the threshold, enable the experimenter to decide whether the micro-electrode is in contact with the fibre of a single ganglion cell.

The following types of spectral sensitivity curve are obtained: (*a*) *scotopic dominator*, a broad curve which by its shape and position in the spectrum and by its appearance in rod retinæ and under conditions of dark-adaptation can be attributed to ganglion cells associated with end-organs for which visual purple (or, for freshwater fish, visual violet) is the photosensitive substance; (*b*) *photopic dominator*, another broad curve, obtained with light-adapted and predominantly cone retinæ, which is displaced some 60–70 mμ towards the red compared with the scotopic dominator of the same retina (when this can be recorded); (*c*) *modulator curves*, comparatively narrow curves obtained with light-adapted retinæ and located at various points of the spectrum from about 440 to 610 mμ, possibly in groups in the red, green and blue regions; (*d*) *composite curves*, which can be regarded as the 'summation' of a dominator and a modulator or of two modulators.

From replies to questions on the relative frequency with which dominator and modulator curves are obtained, it appeared that perhaps one in twenty curves (presumably for light-adapted retinæ) would be of modulator type. A new worker in this field, de Vries (Groningen) reported that he had had no difficulty in obtaining dominator curves, but had not yet observed a modulator curve.

Some criticism was expressed of Granit's second method of obtaining modulator curves, the method of selective adaptation. The modulator curve is derived by taking at each wave-length the difference between (*a*) the sensitivity (reciprocal threshold energy) of an element after strong adaptation to coloured light, and (*b*) the reduced sensitivity of the same element in the fully dark-adapted state, that is, the dark-adapted sensitivity reduced by a constant factor so chosen that the difference in question is zero at some wave-length and is nowhere negative. One of several assumptions underlying this procedure is that both rods and 'modulator receptors' are connected to the ganglion cell, the fibre of which is in contact with the micro-electrode, and that the effects of radiational quanta absorbed in rods and modulator receptors are summed at the threshold just as if they were all absorbed by a single end-organ.

Pirenne (London) and others found this latter assumption difficult to accept. Apart from the difficulty of justification, however, the procedure used leads to modulator curves for the cat's retina which are very similar to those obtained for other retinæ by the direct method.

Certain main trends relating the on-or-off character of an element with its spectral response and other properties had been observed. Thus pure on-elements were strongly predominant in pure rod retinæ, while pure off-elements were common in retinæ having no rods. Taking as standard the spectral sensitivity curve corresponding to light absorption by visual purple, Granit and Tansley (Birmingham) found that off-responses, particularly those from pure off-elements, were in general relatively red-sensitive, but on-responses, if they deviated at all, did so in the direction of blue-sensitivity. From these and similar results Granit was led to group together rods, on-effects and blue-sensitivity on one hand, cones, off-effects, inhibition and red-sensitivity on the other.

In the latest micro-electrode work, Granit and Gernandt (Stockholm) had found that if, instead of illuminating the retina, a polarizing current of about 0·1 mA. was passed through it, on-elements gave an on effect and off-elements an off effect for one direction of the polarizing current and the reverse effects when the current was reversed. On-off-elements behaved to the polarizing current either like on-elements or like off-elements, depending on the relative strengths of their on- and off-responses to the ordinary light stimulus. The effect of a polarizing current on the spectral sensitivity curve of an element was expressed by taking at each wave-length the *ratio* of the light thresholds with and without polarizing current. The ratio curves so obtained show peaks and depressions at various parts of the spectrum, different for different current directions and for elements of different type. These peaks and depressions are assimilated to the modulator curves obtained by the method of selective adaptation. In Granit's view the polarization method provides the most satisfactory way of determining modulators. The bearing of the polarization results on the question of inhibition in the neural network of the retina was also discussed by Granit.

A paper by Polyak (Chicago) on retinal structure and colour vision was read by Le Gros Clark (Oxford). Le Gros Clark also summarized the evidence for his interesting suggestion that conduction from the central retina is mediated by three-fibre units, the respective fibres terminating in corresponding cell layers of the lateral geniculate body, and that this triplicity is closely related to the trichromatic basis of colour vision. One supporting observation was obtained from a war-time experiment in which monkeys kept in red light for some weeks showed, in two out of three animals, a degeneration of the cell layers associated by other evidence with the 'blue' mechanism. Oddly enough, this presumed atrophy by disuse affected mainly the layer of 'blue' cells receiving crossed fibres. Two of the main points made by Polyak were that in the extrafoveal retina the ganglion cells are generally connected through bipolars to both rod and cone end-organs, and that in the central fovea the end-organs are structurally indistinguishable, although connected in different ways through bipolars to the ganglion cells.

The latter conclusion cuts across the hypothesis recently developed by Willmer (Cambridge), according to which the end-organs of the central fovea are of two kinds, cones and non-adapting or day rods. Willmer suggested that the staining reactions used by Polyak to identify rods might pick out only those which have the capacity of accumulating visual purple in the dark and might fail for day-rods. Willmer, after summarizing the phylogenetic argument for his hypothesis, presented some new sensory measurements on the luminosity curves of colour-blinds obtained with small test fields in the central fovea. Under these conditions, normal trichromats behave like dichromats (tritanopic), while dichromats are reduced to monochromats. The differences in the luminosity curves of various colour-defectives were correlated by Willmer with the several possible end-organ-ganglion cell systems consistent with his hypothesis. Also the actual shapes of the curves were related to the absorption curves of rhodopsin and iodopsin.

In the discussion, this last step was strongly criticized for the same kind of reason as already noted in connexion with Granit's derivation of modulator curves by selective adaptation. In fact, one main impression from the Conference was that workers on vision have been prone to take differences of experimental curves or to apply other mathematical manipulations to their data without a proper discussion of the kind of summation, inhibition or other process which is automatically assumed to occur in the organism whenever particular mathematical methods are applied.

Wald (Harvard) reviewed the considerable knowledge we now have of the rhodopsin–retinene$_1$–vitamin A$_1$, and the porphyropsin–retinene$_2$–vitamin A$_2$ photochemical systems of the retina. Morton (Liverpool), who has recently obtained retinene$_1$ in the crystalline state, explained briefly his reasons for attributing to retinene$_2$ a structure differing from retinene$_1$ by one additional conjugated double bond in the ring. The extraction by Bliss (Boston, U.S.A.) of a substance termed cephalopsin, a kind of non-bleaching visual purple, from the eye of the squid raised interesting possibilities. No substantial advance in the difficult problem of extracting from the retina photosensitive substances which might be assigned to cones or to hypothetical end-organs possessing spectral sensitivities of modulator type was reported. Wald showed how measurements of the absolute light threshold in the visible and ultra-violet for parafoveal rod vision and foveal and parafoveal cone vision on normal and aphakic eyes led to determinations of the absorption curves of the macular pigment and of the eye lens. The results were in satisfactory agreement with his direct measurements on preparations from human eyes. The macular pigment could be identified as a xanthophyll, probably ordinary lutein.

Turning to purely sensory studies of colour vision, MacAdam (Rochester, U.S.A.) explained how by the use of Landolt test objects (*a*) of usual type, (*b*) with the broken circle of one colour and the background of different colour but equal brightness, he had succeeded in comparing the visual acuities attributable respectively to pure brightness and pure colour contrast. Taking as standard the relative importance of colour and brightness contrast in determining the observed discrimination in a 2° colorimeter field, colour contrast was found to be much less effective in the acuity observations, which depend on discrimination in small areas. At the other extreme of large non-contiguous areas, colour contrast was much more effective than brightness contrast. As fixation was not controlled in the acuity measurements, the results were not directly comparable with those of Willmer and Wright (London) showing tritanopic colour defect in the central fovea, and, in fact, the loss of colour discrimination was not of this specific type.

Wright considered the recent work on colour matching and discrimination in small fields in his talk on the present status of the trichromatic theory. His general conclusion was that the theory in some form is necessary to explain some of the known facts and, at the same time, it is not inconsistent with much of the remaining data. According to Stiles (Teddington) the observed foveal thresholds of a coloured light patch superimposed on an adapting field of, in general, a different colour are consistent with a classical trichromatic theory and lead to fundamental response curves of König type. But from the threshold recovery curves obtained after extinguishing the adapting field, it appears that the 'blue' mechanism has very different dynamics from the 'green' and 'red' mechanisms, a result already indicated by Wright's studies of colour adaptation by the binocular matching method. The difficulty of reconciling three fundamental response curves which are widely separated in the spectrum (for example, curves of

König type) with the apparent saturations of different spectral colours was enunciated by Hecht (New York), who also raised the problem of the sensations experienced by subjects with one normal and one colour-defective eye.

In the discussion two issues were separated: (*a*) differences in the number of just perceptible colour steps between white and the various spectrum colours; (*b*) the relation between the descriptions of colour sensations given by normals and various types of colour-defectives. Wright argued that attempts to explain (*a*) on the basis of the trichromatic theory, while not without some success, were too mechanistic. On (*b*), it was suggested that the colour names applied by colour-defectives are determined during the development of the individual so as to give, under the conditions of everyday life, the greatest measure of agreement with the names used by colour normals; or, in the case of a single defective eye, maximum agreement between the names which would be applied when the two eyes were used in turn.

Judd (Washington, U.S.A.) found the explanation of the colour sensations experienced by colour-blinds the principal stumbling-block to the interpretation of dichromatic vision on the trichromatic theory. He summarized several alternative views according to which a different form of explanation of colour vision is required for the various stages (photosensitive, substance, receptor, optic nerve, cortex) of the visual process.

By measuring the foveal threshold sensitivity through the spectrum, Hecht had deduced that the effective luminosity of an equi-energy spectrum would be, for the protanope, about one half and, for the deuteranope, about three fifths that of the normal. On the assumption that luminosity is the dominant factor in determining differences of visual acuity between normals and colour-defectives, he tested and confirmed this result by acuity measurements on subjects of the three types. de Vries determined the modification in brightness match between green and red stimuli when the matching field was covered by a veiling brightness of red or blue light. The modified matches agreed with those obtained in the absence of the veiling brightness by protanopes and deuteranopes respectively. This result and that of Hecht appear to support the simple theory of dichromatism as the loss of a receptor system.

Pitt (Harrow) developed the interesting suggestion that for protanomalous trichromats only the 'red' fundamental response curve is aberrant, this curve being related to the corresponding normal curve by some modification of form, progressive with increasing anomaly, and perhaps resembling the change of the absorption curve for a layer of increasing thickness. Schouten (Eindhoven) put forward related ideas for both deuteranomalous and protanomalous cases. Hecht questioned the usual interpretation of anomaloscope studies of large groups as showing a continuous transition between the normal and the anomalous. By taking account of the whole range of uncertainty in each subject's setting of the anomaloscope, he concluded that the groups are clearly separable without overlap. Farnsworth (New London, U.S.A.) showed a pseudo-isochromatic chart, which he had designed and made up from Munsell colour patterns, for the detection of tritanomalous subjects, a type which is likely to have escaped earlier tests of colour defect. The genetics of colour vision were not discussed in any detail, but Kalmus (London) made a plea for the study of the colour vision of heterozygous females.

Of the several points raised by Hartridge (London) in developing a polychromatic theory of vision, his use of the negative values in sets of fundamental response curves like those of Wright as an argument for additional receptor mechanisms was not generally acceptable. On the other hand, Dimmick (New London, U.S.A.) and Schouten were sympathetic to certain aspects of the theory, which they consider are in better accord than the usual trichromatic presentation with the psychological analysis of sensation.

Measurements, by a new method, of the chromatic aberration of the eye, which is of particular importance in the recent studies of colour in small fields, were presented by Ivanoff (Paris). His results agreed satisfactorily with other new measurements by American workers. Hecht, Shaer, and Pirenne's notion of quantum fluctuations in the stimulus as the main factor in determining the intrinsic indefiniteness of absolute threshold values was discussed by Van der Velden (Utrecht) and Bouman (Utrecht). By extending the theory to take account of variations of threshold with the area and exposure-time of the test stimulus, they conclude that the absorption of two quanta is sufficient to initiate a response. Hecht reported new work on the effects on the threshold of the size and shape of the test stimulus. He found that the dominant factor is the length of the boundary edge rather than the area.

It was a great pleasure to all present to have the Conference opened by the veteran of the subject, Sir John Parsons.

W. S. STILES

OBITUARIES

Dr. Ellsworth Huntington

DR. ELLSWORTH HUNTINGTON, who died recently at the age of seventy-one, was well known for his views on the dominant effect of climate on human affairs. As a student of geography under Prof. W. M. Davis, he spent the years from 1900 to 1906 in the exploration of Asia Minor and Central Asia, his first paper being an account of the Upper Euphrates published in 1902. In Central Asia he was struck by the evidence that large populations formerly inhabited regions now arid and deserted, and from these and other historical studies, including the changes of level of the Caspian Sea, he developed the theory that during the past few thousand years there have been great oscillations of climate. These researches were published in "The Pulse of Asia" in 1907 and aroused much controversy among geographers. In the following years he extended his studies of climatic change to Palestine and North America, and he was one of the pioneers in the measurement of tree-rings as climatic indicators. These researches led him to the view that the ideal climate for human vigour is one of moderate but rapidly fluctuating temperatures, which is best developed in the storm-belts of temperate latitudes; and in "Civilization and Climate" (1915) he compared estimates of the level of existing civilizations in different countries, obtained in various ways, with their level of climatic energy, finding remarkably close agreement. In the same book he extended his studies of the effect of climatic changes on the history of ancient civilizations, including a new version of the decline and fall of the Roman Empire.

Huntington followed up these ideas in great detail in a series of articles and books—"World Power and Evolution", "The Pulse of Progress", "Weather and Health", "Season of Birth", "Mainsprings of Civilization", etc. He believed that the origin of climatic variations was to be sought in the sun, and especially in shifts of the storm belts associated with changes in sunspot activity. This hypothesis fits well enough with historical changes of climate; but he stretched it too far when, in conjunction with S. S. Visher, he based a theory of ice ages on increases in the number of sunspots. His rather wild hypothesis of the electro-magnetic influence of the fixed stars on solar radiation found no favour with astronomers. In his later years Huntington became interested in the study of weather cycles, and he was one of the originators of the Foundation for the Study of Cycles which was established in the United States.

Huntington's books were all eminently readable and full of ideas, but at times his claims were exaggerated; for this reason his books had less influence than they might have done had they been phrased more cautiously. On the other hand, he did much to arouse interest in historical variations of climate. In the early 1900's, climate was generally believed to have remained static for thousands of years; "The Pulse of Asia" shattered this calm and began a controversy which has added much to our knowledge.

C. E. P. Brooks

We regret to announce the following deaths:

Mr. William Densham, who assisted Marconi in his early experiments in the Isle of Wight, at Poldhu, Clifden and in America, on October 25, aged seventy.

Prof. Henryk Hoyer, emeritus professor of comparative anatomy of the Jagiellonian University, Cracow, widely known by his work on the comparative anatomy of blood and lymph vessels of vertebrates, on October 17, aged eighty-three.

Sir Leonard Pearce, C.B.E., engineer-in-chief to the London Power Company, who was responsible for the engineering design of the Battersea Power Station, on October 20, aged seventy-four.

NEWS and VIEWS

The Royal Wedding

Since attaining her twenty-first birthday in April of this year, during the tour of the Royal Family in South Africa, Princess Elizabeth has been taking a prominent part in many public functions. Thus apart from the general affection among the public which has been inspired by the sympathetic understanding and devotion to duty of the Royal Family, the people at large have had increased opportunities of learning to know Princess Elizabeth. In these pages it is appropriate to refer particularly to her association with, and interest in, scientific and similar bodies. Early this year, she was elected an honorary member of the Institution of Civil Engineers, and shortly afterwards she became a Royal fellow of the Royal Society. She has also accepted the office of president of the Royal Society of Arts, the activities of which were of deep concern to Prince Albert and in memory of whom the Society's premier award, the Albert Medal, was founded. In her address from the chair at the opening meeting of the present session of the Society, she stressed the importance of design, not only from the point of view of usefulness, but also from that of æsthetics. The industrial revolution, she said, had left a legacy of squalor, misery and ugliness, which was followed by a fall in standards of taste accompanying mass production methods. It is our duty to lead the world in finding a remedy and "to establish that beauty is as essential to utility as it proverbially is to truth". Scientific workers will wish to be associated with the good wishes which are being conveyed to Princess Elizabeth and Lieut. Philip Mountbatten from every part of the world on the occasion of their marriage.

Scientific Adviser to the Ministry of Food: Dr. N. C. Wright

Dr. N. C. Wright, director since 1928 of the Hannah Dairy Research Institute, Ayr, has recently been appointed to succeed Sir Jack Drummond as scientific adviser to the Ministry of Food, being seconded during the period of this appointment from the directorship of the Institute. Dr. Wright is a graduate of Oxford, and during his post-graduate training, carried out research in biochemistry at Cambridge, at the National Institute for Research in Dairying, Shinfield, and in the United States, where he held a Commonwealth Fund Fellowship during 1926–28. While at Shinfield, he investigated, with Mr. W. L. Little, the etiology of milk fever in cattle. These investigators were the first to point out the fall in blood calcium accompanying this disease, a discovery which laid the foundation for the modern method of treatment. Dr. Wright was appointed first director of the Hannah Institute in 1928, and the noteworthy progress of that Institute has been largely due to his efforts. He and his collaborators have, among other researches, examined the influence of heat on the behaviour of milk proteins, the mechanism of the secretion of calcium, phosphorus and other milk constituents by the mammary gland, the differences in biological value for milk secretion of various mixtures of food proteins in common use in the rations of dairy cows, and they have made valuable contributions to knowledge in each of these fields.

Dr. Wright has also in recent years studied the questions, at present of great national importance, of the feeding-stuffs requirement of farm animals in relation to home and overseas supplies, and the rival claims, under war-time conditions in Britain, of animals and man for food. His appointment at the Ministry coincides in time with the agricultural expansion programme for greater home production of food, a programme which largely depends for its implementation on the increased importation from overseas of animal feeding stuffs. Dr. Wright's recent studies will doubtless be of especial value in relation to this importation, which is a function of the Ministry of Food. Since 1936 he has paid several advisory visits overseas: to India, the Middle East, Ceylon, and recently to Greece with a mission of the United Nations Food and Agriculture Organisation, mainly in connexion with food production and livestock problems.

Discovery of Chloroform Anæsthesia

The discovery of the use of chloroform as an anæsthetic, made by Sir James Young Simpson in Edinburgh in 1847, was marked by a graduation ceremony at the University at which the honorary degree of LL.D. was conferred on Dr. H. W. Featherstone, founder-president of the Association of Anæsthetists of Great Britain, and Mr. T. B. Simpson, a grand-nephew of Simpson. A meeting to discuss the present-day use of chloroform was also held, at which Prof. R. R. Macintosh (Oxford) and Drs. D. S. Middleton and John Gilles (Edinburgh) read papers. Dr. Douglas Guthrie, lecturer on the history of medicine in the University of Edinburgh, gave an address at a reception in the Upper Library, where an exhibition of Simpson relics had been arranged. Dr. Guthrie said that the discovery of chloroform anæsthesia was one of the most dramatic episodes in the history of medicine, and with antiseptics had revolutionized surgery; it was remarkable that it had been delayed until the middle of last century. After graduating M.D. at Edinburgh in 1832, Simpson became assistant to Prof. John Thomson, professor of pathology, who advised him to specialize in midwifery. He was appointed professor of midwifery in the University in 1840, a post which he held until his death at the early age of fifty-nine in 1870. Since the discovery by Simpson of the anæsthetic properties of chloroform, there have been great advances in the technique of its administration, to which he himself contributed; and in spite of the introduction of many new substances, it still holds its place as a general anæsthetic.

Carl Friedländer (1847–87)

Friedländer's name is familiar to every medical student through 'Friedländer's bacillus', which, he described in 1882. A capsulated micrococcus, this is not now considered pathogenic for true lobar pneumonia, though it may cause the accompanying septicæmia. A native of Brieg in Silesia, Carl Friedländer was born a century ago on November 19, 1847. After taking the M.D. at the University of Berlin, he became assistant to Friedrich von Recklinghausen at Strassburg in 1874, and five years later was appointed to the modest post of assistant superintendent of post-mortem examinations in the Friedrichshain Hospital, Berlin. The courtesy title of professor was conferred on him only a few months before his death. Founder-editor of the *Fortschritte der Medicin*, Friedländer brought that journal to the front rank of German scientific periodicals. Among his most original work may be mentioned his description of thromboangiitis obliterans and his recognition of the tuberculous nature of lupus. He himself was a victim of pulmonary tuberculosis, which first manifested itself about 1882. His "Mikroskopische Technik" was a manual valued by student and expert alike.

Dr. Charles Creighton (1847–1927)

Founder of modern British epidemiology, Charles Creighton, who was born on November 21, 1847, towered above his fellows yet partook of their foibles and frailties. After obtaining the M.D. at Aberdeen in 1878 and studying in Berlin and Vienna, he practised for a time in London, but his heart was never in his work. He practically lived in the British Museum, where he collected material for his "History of Epidemics in Britain" (1891–94), described by Garrison as a "classic of unimpeachable accuracy". To the gigantic task of translating unaided Hirsch's "Handbuch der historisch-geographischen Pathologie" for the New Sydenham Society he devoted twelve hours a day for three years. He was the most learned British medical scholar of the nineteenth century, who stood for something fundamental in the intellectual world of his generation. He was handicapped, however, by a curious mental obliquity which forced him to believe that the generally accepted must be necessarily false. Incapable of sharing much of the current medical teaching and frequently clashing with his medical colleagues, he brought matters to a head when in his article on vaccination in the "Encyclopædia Britannica" he declared that cowpox had nothing to do with smallpox, affording no protection against it. This was acclaimed by the antivaccinators, and Creighton was ostracized by the medical profession. He spent his last years in philosophical isolation in a tumble-down cottage at Upper Boddington, turning to Shakespeare for solace. His slender means were amplified by a Civil List pension secured for him by Mr. Asquith, who admired his learning.

Hop Research in Britain

A new research centre has been set up for hop production problems. It is situated at Wye College, Kent, and is to be administered by the College. The Ministry of Agriculture, the Hops Marketing Board and the Institute of Brewing will provide grants to meet the costs of maintenance, and the two last-named will bear the capital costs of establishing the centre. Scientific advice on the programme of work of the new centre and the staff necessary to carry out that programme will be given by the Agricultural Research Council; to assist on technical matters, the Council has a Committee on Hop Research, on which there are members nominated by the grant-making bodies. The investigations at the new centre will include those concerned with soils, cultivation, varieties, breeding, diseases, brewing qualities and storage, and there will be close co-operation with investigations on hop diseases carried out at the East Malling Research Station or elsewhere.

Atomic Energy Train Exhibition

The atomic energy exhibition, organised by the Atomic Scientists' Association, was launched on November 6 at Liverpool by Sir James Chadwick. Speaking of the purpose of the exhibition, Sir James remarked that the excursion of scientific workers from the lecture room and the laboratory into the hurly-burly of public life was forced upon them by the urgency of the situation. Sooner or later the countries of the world will have to come to a decision about atomic energy, the trend of its development and the use to which it is to be put. This decision will have an important effect on the relations between nations and on the establishment of goodwill and confidence between them. In order to come to a wise decision it is necessary that the people at large should understand the fundamental facts. It is one of the aims of the Atomic Scientists' Association to explain to the public the facts about atomic energy. The main feature of the exhibition is the inclusion of experiments of the same type that are used in the laboratory. The first of the two coaches deals with the fundamental facts about atomic energy, and in it several Geiger counters are employed in order to demonstrate radioactive phenomena. The production of artificial radioactivity in silver by bombardment with slow neutrons is also demonstrated. The second coach deals with the practical applications of atomic energy, and it starts with a demonstration of the detection of fission in uranium. The gas diffusion, thermal diffusion and electromagnetic methods of isotope separation are all demonstrated on working models. The application of radioactive elements to medicine is illustrated on a film. All experiments are arranged to run automatically, but a member of the Atomic Scientists' Association is in attendance to give additional explanations.

The exhibition was first open to the public in Chester on November 10. It went from there to Stoke, and its further itinerary includes Manchester, Blackpool, Carlisle, Glasgow, Dundee, Aberdeen, Edinburgh, Newcastle, Middlesbrough, York, Leeds, Sheffield, Derby, Coventry, Nottingham, Leicester, Birmingham, Shrewsbury, Swansea, Bristol, Cardiff, Oxford, Reading and London. Efforts are being made to extend the duration of the exhibition to enable it to visit more places in the south of England. Inquiries about the exhibition should be addressed to Dr. J. Rotblat, Physics Department, University of Liverpool.

Starch Hydrolysis by Polarized Light

It has earlier been reported that exposure to polarized light induces hydrolysis of starch both *in vitro* and in the mesophyll of leaves. Now Dr. Elizabeth S. Semmens (*Plant Physiology*, 22, 270–278; 1947) describes experiments on the effect of polarized light on the starch content of stomatal guard cells. With a variety of plants and using both detached strips of epidermis and whole leaves attached to the parent plants, polarized light induces starch hydrolysis in the guard cells of the stomata; and this hydrolysis is accompanied by stomatal opening. Although in some cases the periods of exposure that preceded the observations were somewhat prolonged, these effects were also found when the period of exposure was only a few hours. With polarized direct sunlight the starch hydrolysis proceeded more vigorously, and bursting of the guard cells sometimes occurred. Although it appears likely that these observations, regarded as preliminary by the author, may, when extended, make a contribution to our knowledge of the vexed problem of stomatal mechanisms, their precise significance is at present difficult to assess.

Dominion Observatory, Wellington

The annual report for the year 1944 of the Dominion Observatory, Wellington, N.Z., shows that there was a general decline in seismic activity as compared with previous years. There was some concentration of activity south of Lake Taupo, but the intensity anywhere did not exceed V + on the modified Mercalli scale and the shocks were not destructive. Sixty-one tremors were felt in the North Island, forty in the South Island and six in both. The Jaggar seismograph at Hastings was in operation again by July and the seismographs at Auckland, Arapuni, Tuai, New Plymouth, Bunnythorpe, Wellington, Takaka, Kaimata, Christchurch and Monowai were recording throughout the year. The death occurred on May 24, 1944, of Mr. A. W. Burrell of Stratford, who for some time operated a Jaggar seismograph for the Department of Scientific and Industrial Research in the Dominion.

National Museums of Ceylon

This Director's report for 1945 (published 1946) on the national museums of Ceylon includes the Colombo, Kandy, Ratnapura, Jaffna and Navala Museums. All have suffered, in varying degrees, the difficulties associated with requisition, evacuation, or other war-time contingency, and in some cases results have been serious. The present report, however, shows that these institutions are now returning to their normal peace-time activities. From the Colombo Museum, for example, it is reported that the important work on the Museum's collections in relation to Ceylon's extinct mammals, living fauna, prehistory and certain antiquities, was resumed and the results published during the year. Damage and losses are still being assessed in this Museum, and the Jaffna Museum reports that only a very small part of the Twynam collections (stored in the Old Dutch Church) will be fit for exhibition again. Lists of acquisitions in respect of each museum are given in detail.

Anthropological and Archæological Work in India

The *Journal of the Indian Anthropological Institute*, vol. 1 (New Series), 1945, contains a number of interesting articles. Desiccation of Asia and its effect on human occupation is discussed by the late Sir Aurel Stein. Colonel Gordon surveys ancient Gandhara, and also describes some rock engravings and microliths in the Bangalore area. Colonel Gordon has long ago shown that most of the rock-shelter paintings and the rock carvings in India cannot be of any considerable antiquity. Nevertheless, such finds are of great interest, even if not very ancient. There are also papers on megalithic monuments of southern India by A. Aiyappan, and on Gond exogamy by M. P. Buradkar.

French Scientific Library in London

A small French scientific library is being built up at the Institut Français du Royaume-Uni, London. Both books and periodicals can be borrowed by post. In addition, microfilms of articles appearing in periodicals not available in the library can be obtained from France. These can either be consulted in the library, where a microfilm reader has been installed, or borrowed by post. All the library services are provided free. A catalogue of the books and periodicals available can be obtained from the Librarian, Scientific Library, Institut Français du Royaume-Uni, Queensberry Place, South Kensington, London, S.W.7.

Institution of Civil Engineers: Council for 1947–48

The Council for 1947–48 of the Institution of Civil Engineers is as follows: *President:* Sir Roger Hetherington; *Vice-Presidents:* Sir Reginald Stradling, Sir Jonathan Davidson, W. H. Morgan, V. A. M. Robertson; *Other Members of Council:* H. E. Aldington, Sir Stanley Angwin, Prof. J. F. Baker, G. Baxter, D. B. Brow (India), W. S. Cameron, F. M. Corkill (New Zealand), H. F. Cronin, Sir Arthur Dean (India), Dr. W. H. Glanville, A. Gray (Canada), Dr. E. J. Hamlin (South Africa), A. C. Hartley, G. H. Humphreys, Sir Claude Inglis, L. Leighton, H. J. B. Manzoni, M. S. Moore (Australia), Prof. A. J. S. Pippard, A. S. Quartermaine, J. C. L. Train, W. K. Wallace, Sir Arthur Whitaker; *Past-Presidents:* Dr. D. Anderson, F. E. Wentworth-Sheilds, Sir Peirson Frank, Sir William Halcrow; *Secretary:* E. Graham Clark.

A New Technique for Studying the Helium Film

In previous experiments the properties of the helium film and the mechanism of the transport in this film have been investigated systematically[1]. However, all these measurements were carried out with the bulk liquid present, and the film was therefore always under the vapour pressure of the latter. We have now developed a technique which permits the study of the film in equilibrium with the gas phase only, thus reducing the observations to the simpler case of a two-phase (film-gas) equilibrium. Use is made of the frictionless flow of the film through capillary leaks below the λ-point.

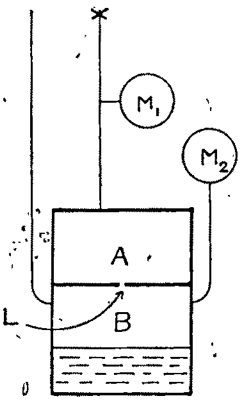

Fig. 1

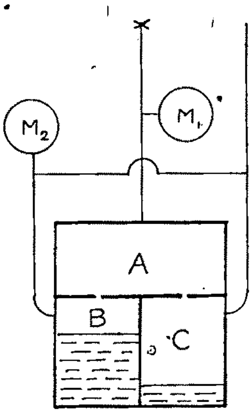

Fig. 2

Two containers, A and B (Fig. 1), the latter containing liquid helium I, are connected by the capillary leak L. If A is evacuated and then closed off, helium *gas* will leak from B through L into A, the rise of pressure in A being measured by the gauge M_1. When the liquid helium in B is cooled below the λ-point, however, a new process makes its appearance. Helium in the form of the transfer film now runs up the sides of B and passes over the perimeter of L into A, thereby constituting an additional leakage. By using progressively smaller capillary leaks, the stage can be reached where the gas leakage becomes insignificant compared with the film leakage, and it is then possible to study the film in A under varying gas pressures independent of the vapour pressure of the liquid. Tubes containing closely packed wires such as used by Allen and Misener[2] in their work on the viscosity of the bulk liquid were found to provide suitable capillary leaks.

The first experiments undertaken were determinations of the equilibrium pressure which will be set up in A through film leakage from B; that is, the vapour pressure of the film. However; some of the results obtained at first sight appeared quite paradoxical. In a number of experiments, the pressure in A rose not only to the value of the vapour pressure in B, which was measured independently on the gauge M_2, but surpassed it, settling at a higher value. The reason for this curious behaviour was indicated when it was found that in these cases, owing to the heat influx from outside, the container A was slightly warmer than the liquid in B. By purposely increasi the temperature of A, it could be made to fill up an equilibrium pressure more than twice as high the vapour pressure in B. Daunt and Mendelssoh have found that there exists a thermo-mechani effect in films similar to the fountain effect in t bulk liquid[3], and it would seem that in the prese case helium is transferred by the film to a regi of higher temperature and consequently high vapour pressure. This observation raises the intere ing question (to be settled by further experimen as to whether under these conditions the helium in will appear in the form of bulk liquid, and wheth there exists a temperature gradient in the trans film itself.

The new technique of studying the helium film c be applied to a wide range of problems. For examp by introducing a second capillary leak (Fig. 2) leadi into a third container C, which is also filled wi liquid helium II, but at a lower liquid level th that in B, the transfer of liquid by means of the fi from B through A into C can be studied. Prelimina experiments have shown that the transfer persi even when the pressure in A is reduced below t vapour pressure of the bulk helium. Other expe ments under way concern the actual temperatu of the film under various conditions and the spe of heat impulses along the film with the gas pha completely excluded. We are indebted to Dr. D. K. MacDonald for help during the experiments.

Electron Density in Meteor Trails

Contemporary studies of the radio echoes fro meteors indicate that dense transient concentratio of electrons are produced by the meteors at heigh of 90–120 km. above the earth's surface[1,2] Eckersley[4] calculated the intensity of scatter radio waves by assuming that the electrons we produced in a small cloud, and Pierce[5] by assumi that the electrons were produced in a long colum of diameter *large* compared with the wave-length the radio wave.

Recent experimental work on higher frequenci in the region of 60–70 Mc./s. has shown that the ma radio echo is obtained only when the aerial beam directed at right angles to the track of the meteor[1] This effect can be explained if the ionization is in t form of a long column, of diameter *small* compar with the wave-length of the incident radio wave. T intensity of a radio wave scattered from such a lo narrow column of ionization in the atmosphere, assu ing that the electrons scatter coherently, has be calculated by Blackett and Lovell[6], and in terms the parameters of the radio apparatus it can be show that if α is the number of electrons per cm. pat formed by the meteor and ε is the power scatter back to the receiver when the aerial beam is direct at right angles to the direction of the trail, then

$$\alpha = \sqrt{24\,\pi}\left(\frac{mc^2}{e^2}\right)\frac{1}{G}\sqrt{\frac{\varepsilon R^3}{P\lambda^3}},$$

where (mc^2/e^2) is the inverse of the classical electron radius, G is power gain of transmitter and receiving aerials over a half-wave dipole (assumed the same), R is distance of meteor trail from the apparatus, P is peak transmitter power, λ is wave-length of apparatus.

The validity of this formula has recently been tested experimentally as regards the predicted variation of received power ε with λ for a given meteor trail. During the Perseid meteor shower of August 1947, simultaneous observations of radio echoes from the same meteor trail were made on frequencies of 72 and 36 Mc./s. and also on 72 and 46 Mc./s. The experiment on 72 and 36 Mc./s. was repeated during a continuous 24-hour watch on September 23–24. For each pair of coincident echoes R and α will be the same, and if G and P are the same for the two equipments, the formula predicts that the ratio of the received powers ε_1 and ε_2 on two wave-lengths λ_1 and λ_2 will be $\varepsilon_1/\varepsilon_2 = (\lambda_1/\lambda_2)^3$. In the actual experiment the quantity measured is the amplitude of the echo on the cathode ray tube display, which can be converted to equivalent voltage input at the aerial by appropriate calibration of the receiver. If the two observed voltages are v_1 and v_2, then

$$\frac{v_1}{v_2} = \sqrt{\frac{\varepsilon_1}{\varepsilon_2}} = \left(\frac{\lambda_1}{\lambda_2}\right)^n,$$

and the theory predicts that the exponent n is 1·5.

107 coincident pairs of echoes were measured with $\lambda_1 = 8{\cdot}3$ m., $\lambda_2 = 4{\cdot}15$ m., and 57 coincident pairs with $\lambda_1 = 6{\cdot}5$ m., $\lambda_2 = 4{\cdot}15$ m., between August 12 and 27. On September 23–24 a further 160 pairs were measured with $\lambda_1 = 8{\cdot}3$ m., $\lambda_2 = 4{\cdot}15$ m. From the measured values of v_1 and v_2, the exponent n has been calculated for each pair and the results are summarized in the accompanying table.

	Number of observations	Number of observations used in calculation	Ratio $\frac{\lambda_1}{\lambda_2}$	Mean value of measured voltage ratio $\left(\frac{v_1}{v_2}\right)$	Mean value of exponent n	Standard deviation
Aug. 12–27 :						
Simultaneous observations on 36 and 72 Mc./s.	107	74	2·0	2·6	1·4	0·5
Simultaneous observations on 46 and 72 Mc./s.	57	38	1·56	2·2	1·8	0·5
Sept. 23–24 :						
Simultaneous observations on 36 and 72 Mc./s.	160	135	2·0	2·4	1·3	0·5

The observed voltages v_1 and v_2 used in these results have been corrected for the differences in peak power P between the three equipments. The main error in the experiment lies in the assumption that the aerial gain G is the same. Although geometrically similar aerial systems were used on the three wave-lengths, slight differences of terrain and surroundings inevitably introduce variations in the polar diagrams of the aerials. It can therefore be anticipated that a certain number of meteor trails will form in regions where the polar diagrams of the two comparison equipments are not exactly similar, and hence give rise to a considerable scatter of the results about the mean value. In deriving the results given in the table, coincident pairs showing deviations from the mean exponent greater than three times the average deviation have been rejected.

The results are in reasonable agreement with the predicted relation between ε and λ, and although more experiments are needed to establish the exact relationships, it now seems plausible to assume that the fundamental assumptions made in deriving the formula are not seriously in error for radio wave frequencies in the 30–70 Mc./s. region.

By using this formula it is possible to calculate the electron density in meteor trails, since G, P and λ are constants of the apparatus and ε and R are measured for individual echoes. The densities measured (with $G = 4$, $P = 70$ kW., $\lambda = 4{\cdot}15$ m.) lie in the range 10^{10}–10^{12} electrons per centimetre of path. Triple simultaneous observations of meteors on the two equipments and visually were also made during this experiment. These results show that a 5th magnitude meteor which is near the limit of naked eye visibility produces about 2×10^{10} electrons per centimetre of path. These results for electron densities lie in the same region as those found by combined visual and radio echo measurements on the 1946 Perseid shower[2].

These experiments were made at the Jodrell Bank Experimental Station of the University of Manchester in conjunction with J. A. Clegg, J. G. Davies, C. D. Ellyett and V. A. Hughes.

A New Technique for Following the Attack of Metallic Mirrors by Free Radicals

THE removal of metallic mirrors is a well-established technique for the detection and identification of free radicals produced in the decomposition of organic compounds. The rate of removal of mirrors is usually followed by photometric means, in which the opacity of the mirror is matched against that of a standard. In the course of an investigation into the attack of free radicals on coal and coal by-products at high temperatures, it was found that the evolution of smoke and tarry material tended to make the use of optical methods somewhat unreliable. It was thought that measurement of the electrical conductivity of mirrors could be applied to the problem and, in particular, glass elements of the type used in the measurement of the dewpoint of combustion gases containing sulphur oxides[1] seemed to be ideal for this purpose.

The elements used have been described in detail by Dooley and Whittingham and consist of a 'Pyrex' tube closed at one end into which two platinum–platinum-rhodium thermocouples are fused. The convex surface is carefully polished so that the thermocouples lie correctly in the surface, and a known potential is applied across the gap, the current passing being measured on a micro-ammeter.

The temperature of the surface can be accurately recorded, and the deposition and removal of extremely thin metallic mirrors is reflected in changes in the electrical conductivity across the gap between the thermocouples. The use of this technique can best be illustrated by reference to some exploratory work carried out on the decomposition of lead tetraethyl.

The element was fitted with a ground-glass joint, to permit ease of removal, and was placed at one end of a long 'Pyrex' tube through which a rapid stream of oxygen-free nitrogen, at a pressure of 1–2 mm., was passed. The nitrogen was charged with lead tetra-ethyl vapour by passage through a trap, maintained at − 78° C., containing lead tetraethyl. The area of glass between the two thermocouples, approximately 0·5 sq. cm., was heated either by a small platinum spiral inserted inside the element, or by directing a stream of air through an electrically heated quartz tube on the underside of the element.

On heating the glass a slow increase in conductivity due to the production of a lead film was first observed at 180° C., and a more rapid build-up took place at 200–220° C. These temperatures are well below those at which the glass begins to exhibit conductivity. After the conductivity had increased to any desired value the source of heat was removed, and the element allowed to cool to room temperature. The tube through which the nitrogen – lead ethyl mixture passed was then heated at different distances from the element, and the accompanying table gives values obtained for the time of removal of the mirror (θ) at a distance d from the point at which the ethyl radicals are produced. The streaming velocity of the gases was 11 metres per sec. and the life of the radical (t) is therefore $d/1{,}100$ sec.

Distance, d, in cm.	Life, t, in sec.	Removal time, θ, in sec.	$\log_{10} 1/\theta$
4	$3\cdot6 \times 10^{-3}$	26	$\bar{2}\cdot5850$
8	$7\cdot2$	31	$\bar{2}\cdot5086$
12	$10\cdot9$	45	$\bar{2}\cdot3468$
18	$16\cdot4$	65	$\bar{2}\cdot1871$
28	$25\cdot4$	120	$\bar{3}\cdot9208$

From the plot of $\log_{10} 1/\theta$ against t the half-life period of the ethyl radicals was found to be $1\cdot4 \times 10^{-2}$ sec. No difficulty has been encountered either in depositing reproducible mirrors of a given thickness or in obtaining consistent times of removal.

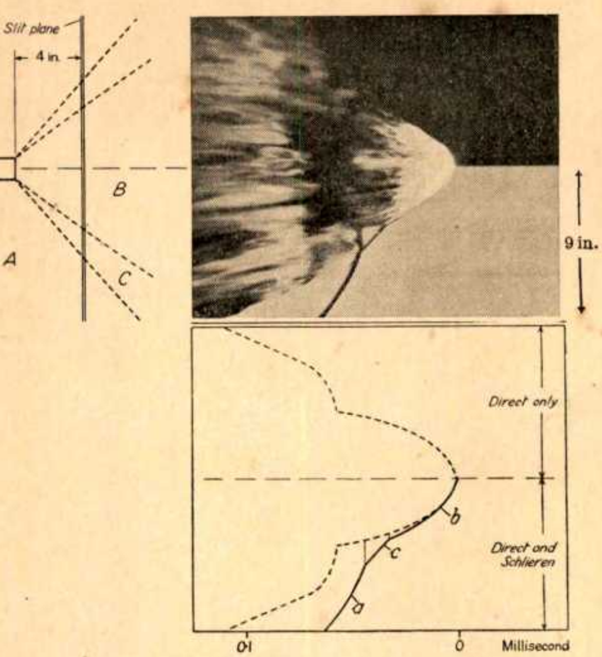
Mach Waves in Shock Wave Systems from Detonating Explosives

WE have recently obtained many photographs of Mach waves[1], known alternatively as 'bridge' or 'Y' waves[2], in the shock wave systems resulting from the detonation of unconfined charges of solid explosive. Waves of this type, which Mach postulated from the observation of soot patterns, are produced when supersonic waves intersect at obtuse angles of incidence. Instead of the simple intersection (which obtains in collisions at acute angles as well as in collisions of sonic waves at any angle of incidence), there is formed a Mach wave which travels in a direction parallel to the plane of symmetry bisecting the angle between the original colliding shock waves.



The accompanying *Schlieren* photograph, taken with the Buxton rotating-mirror camera, depicts the development of the flame and shock wave system in a plane 4 in. beyond the end and at right angles to the axis of a right cylinder of cast 30 : 70–tetryl/T.N.T., 1¼ in. in diameter (velocity of detonation 7,030 m./sec.). The diagram to the left of the photograph indicates the position of the charge with respect to the camera slit. The lettered diagram below the record shows a lateral wave a, a terminal wave b and an intermediate wave c, all in full line; the broken line represents the boundary of the products of the detonation. Waves a and b arise in a way previously proposed[3], a during the passage of the detonation wave along the charge, and b from the detonation of the ultimate layers of explosive. The impulses are directed, one very nearly in the equatorial plane and the other along the axis; wave c is a Mach wave arising from the progressive collision of a and b at sufficiently oblique incidence.

From plottings of the linkage points of c with a and with b as measured on records of the shock wave system in different planes, curves can be derived which outline a widening annular region swept out by the Mach wave c. The section of this region is a funnel with smooth boundaries which curve towards the axis, the inner more so than the outer. The position of the funnel C is shown in the diagram to the left of the photograph, the regions marked A and B being those traversed by the waves a and b respectively. As expected, the funnel is generated from the circular periphery of the plane end of the explosive, and its initial direction coincides approximately with the external bisector of the angle between the two intersecting surfaces, that is, at about 45° to the axis in the simple case of the right cylinder. The shape of the Mach funnel and its direction depend, however, on the shape of the charge; for example, a circular Mach wave (as distinct from the above annular type) is generated from the point of a cone, provided that the apical angle is less than about 135°. In similar fashion, it is found that Mach-type discontinuities link the lateral waves from adjacent surfaces of a square prism of explosive.

These photographic experiments have been carried out for the Ministry of Supply, and approval for the publication of this note has been given by the Chief Scientist.

The 'Floating Thread', a Surface Phenomenon on Flowing Water

IN 1936, W. Schmidt[1] described the following phenomenon. When the surface of slowly moving water encounters an obstacle (such as a stick put across a brook and upon its surface), a tiny elevation of the surface is formed at a distance of some decimetres or metres before the obstacle, "appearing like a very fine thread or hair floating on the surface". "Minute floating particles crossing the thread are abruptly retarded and thus accumulate." "That capillary forces are largely responsible for the phenomenon is proved by pouring a liquid of lower surface tension like liquid paraffin over the surface, when the thread is at once displaced upstream by several metres." Schmidt offers no detailed explanation of the phenomenon, and, so far as I know, nothing else was published about the matter.

The surface between the thread (which is perpendicular to the direction of flow) and the obstacle being motionless, the shearing force being in equilibrium with the gradient of surface tension:

$$\mu\left(\frac{\partial v_x}{\partial y}\right)_{y=0} + \frac{d\sigma}{dx} = 0$$

(where y is depth, and velocity of undisturbed flow is $(-v_0, 0)$). The solution of Oseen's equation for the flow along a rigid half-plane[2] gives an approximate formula for the shearing velocity:

$$\left(\frac{\partial v_x}{\partial y}\right)_{\substack{y=0\\x<0}} = -\sqrt{\frac{\rho v_0^3}{-\pi\mu x}}$$

(the half-plane covers the negative x-axis). Whereas the tension of the free-flowing part of the surface upstream of the thread ($x > 0$) has a constant value ($\sigma = \sigma_0$), on the downstream side the tension falls towards the obstacle:

$$\sigma = \sigma_0 - 2\sqrt{\frac{-\rho\mu v_0^3 x}{\pi}}.$$

Thus the distance (d) between the thread and the obstacle is determined with the minimum surface tension (σ_1) which can be attained with the present quantity of capillary-active substance:

$$d = \frac{x(\sigma_0 - \sigma_1)^2}{4\mu\rho v_0^3};$$

in the case of turbulence, that is, at $\rho v_0 d/\mu > 500{,}000$, the formula gives values which are too large.

The hydrodynamic problem was solved by assuming the surface to be plane. A constant value of the pressure (equal to the atmospheric pressure p_0) was found only at the downstream part of the surface, while at the upstream part the calculation gives the difference $p - p_0 = \sqrt{\frac{\rho\mu v_0^3}{\pi x}}$. An approximation for the real shape of the surface, $y = y(x)$, can be obtained by putting the calculated pressure-difference into the equation for the equilibrium between pressure-, gravity- and capillarity-forces:

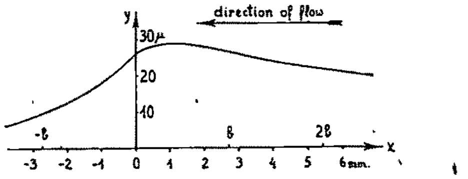
$$\sigma\frac{d^2y}{dx^2} - \rho g y = \begin{cases} 0 \ldots\ldots\ldots\ldots x < 0 \\ \sqrt{\dfrac{\rho\mu v_0^3}{\pi x}} \ldots\ldots x > 0 \end{cases}$$

y and dy/dx must both be continuous at $x = 0$, whereas d^2x/dx^2 becomes infinite at the upstream side. Neglecting now the inconstancy of the surface tension on the downstream side, we get the approximate result:

$$y = \frac{\lambda}{2g}\sqrt{\frac{\mu v_0^3}{\rho b}} \cdot \exp\frac{x}{b} \ldots\ldots x < 0.$$

$$y = \frac{\lambda}{2g}\sqrt{\frac{\mu v_0^3}{\rho b}} \cdot \frac{\lambda}{\sqrt{\pi}} \int_0^\infty \frac{\left(\exp - \left|\frac{x}{b} - \xi\right|\right)}{\sqrt{\xi}} d\xi \qquad \ldots\ldots x > 0.$$

The length $b = \sqrt{\sigma_0/\rho g}$ may serve as a measure of the width of the thread. The maximum elevation is at $x \doteq 0{\cdot}40\,b$; $y_{\max} = 1{\cdot}104y(0)$.



CROSS-SECTION OF THE FLOATING THREAD. THE HEIGHT IS EXAGGERATED 100 TIMES

A numerical example (see figure) may give an idea of the size of the phenomenon. Take $\sigma_0 =$ 70 dyne/cm., $\sigma_1 = 30$ dyne/cm., $\mu = 0{\cdot}01$ poise, $v_0 = 10$ cm./sec. It follows that $d = 126$ cm., $b = 0{\cdot}27$ cm., $y(0) = 0{\cdot}0026$ cm., $(dy/dx)_0 = 0{\cdot}01$ cm. Obviously the results justify the simplifications made above. Very rough preliminary observations seem to agree with the suggested theory (measurements are in progress). With a slight modification the same theory can help to describe the mechanism of spreading of capillary-active films on liquid surfaces, as first observed by Osborne Reynolds[3].

The discontinuity at the thread might seem to present a theoretical difficulty. The infinite curvature at $x = +0$ involves an infinite pressure below that point. Of course, the consideration of the diffusion of the capillary-active substance would have avoided that difficulty. But even without that, it is evident that large pressures do not appear at all; calculation shows that the interval in which the pressure difference would be comparable with the atmospheric pressure is of molecular order of size or smaller.

Mechanical Degradation of Large Molecules

From the thermo-chemical data for the strength of the carbon-carbon single bond (about 5×10^{-3} dynes), the rate of shear was estimated for rupturing the centre bond of large hydrocarbon molecules in solution under laminar flow conditions owing to the component of the viscous drag in the direction of the long axis of the molecule. Experiments confirmed the calculated order of magnitude of the critical value of the rate of shear as a function of the chain-length of the molecule.

Table 1. Percentage permanent viscosity-loss at 20° C. with the number of passages of the liquid through the jet for a 5 per cent solution of a polymer having an average molecular weight above 100,000 with an initial mean rate of shear of $1 \cdot 75 \times 10^5$ sec.$^{-1}$

Apparent percentage permanent viscosity loss from (pt)-values*	Number of cycles through jet	Percentage permanent viscosity loss at low rates of shear	Viscosity-temperature coefficient
0	0	0	− 1·770
4·8	6		
6·3	7		
6·3	8		
7·8	9		
7·8	11		
7·9	12		
8·2	13		
10·0	18		
10·6	25		
11·1	28		
11·1	29		
11·3	30		
13·7	56		
13·8	70		
15·0	71		
13·9	72		
15·2	102		
15·3	103	8·8	− 1·877

* p = pressure difference across jet in cm. mercury, t = time of flow in seconds. The permanent decrease of the (pt)-values of very long molecules (length of the order of 1 per cent of the diameter of the jet) is always larger than the permanent viscosity-loss measured at low rates of shear because turbulence arises with these long molecules even at very low Reynolds' numbers. With the degradation of the molecules this tendency to turbulence becomes reduced.

With an apparatus[1] giving mean rates of shear of the order of 10^5 sec.$^{-1}$ under laminar flow conditions, long-chain molecules of molecular weights above 100,000 were broken down (Table 1), yielding an exponential type of decay curve for the percentage permanent viscosity-loss plotted as a function of the number of cycles of forcing the solution in individual drops through a jet. The mechanical degradation was assessed by the *permanent* viscosity-loss of the solutions at low rates of shear, by the accompanying increase of the viscosity-temperature coefficient of the solutions and by the displacement of the transition region from laminar to turbulent flow towards higher values of the rate of shear as the result of rupturing the largest molecules.

According to the simplifying assumptions made for the calculations, the stretching forces reached their largest value for the centre chemical bond and would increase with the square of the length of the molecule for a given value of the shearing stress. Thus, rates of shear of more than $1 \cdot 6 \times 10^6$ sec.$^{-1}$ would be required for the breakdown of molecules of molecular weights of 25,000 and less.

Table 2. Percentage permanent viscosity-loss with the number of passages of the liquid through the jet for a 5 per cent solution of a polymer having an average molecular weight less than 25,000

Mean rate of shear in sec.$^{-1}$	Percentage permanent viscosity loss at low rate of shear and at 37·8° C.	Number of cycles	Viscosity-temperature coefficient
0	0	0	− 2·813
$3 \cdot 823 \times 10^6$	3·4	500	− 2·846
$3 \cdot 823 \times 10^6$	7·0	2500	− 2·882
$3 \cdot 823 \times 10^6$	9·2	5000	− 2·907
$6 \cdot 324 \times 10^6$	6·0	1000	− 2·885
$6 \cdot 324 \times 10^6$	12·3	5000	− 2·954
1×10^7	8·0	2000	− 2·912
1×10^7	13·0	5000	− 2·979

With a high-pressure jet (to be described elsewhere) calculated to give rates of shear of the order of 10^7 sec.$^{-1}$ for Poiseuille flow, materials of molecular weights of 25,000 and less which remained unaffected in the previous apparatus[1] for rates of shear of the order of 10^5 sec.$^{-1}$ were broken down (Table 2).

Christiansen Filters for the Ultra-Violet

Gaydon and Minkoff[1] have described a Christiansen filter designed to isolate the 2537 A. resonance line of mercury. We have been working for some time upon the general problem of the design of Christiansen filters for the isolation of various spark and discharge tube lines to be used in ultra-violet microscopy. We have amplified the work of Kohn and von Fragstein[2], and developed a series of filters employing benzene–alcohol mixtures with fused quartz chips, which can span the region 3000–4000 A.

The absorption of benzene prevents the use of this combination below 3000 A. Therefore, we have developed a set of filters employing mixtures of purified decahydronaphthalene and cyclohexane,

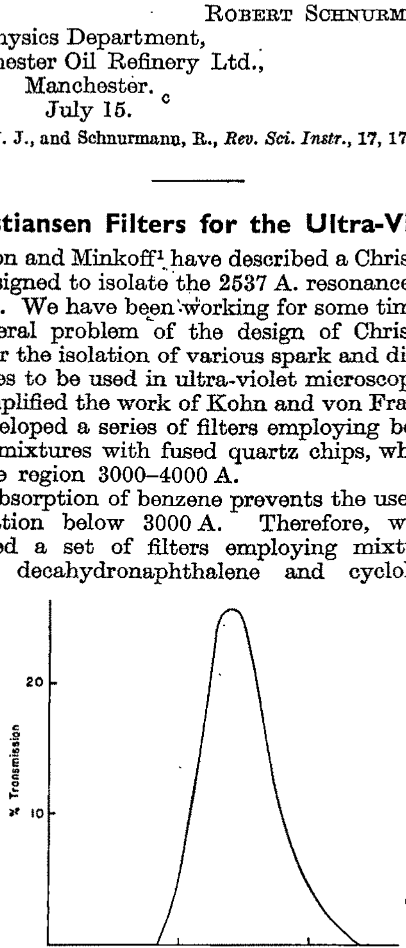

Fig. 1

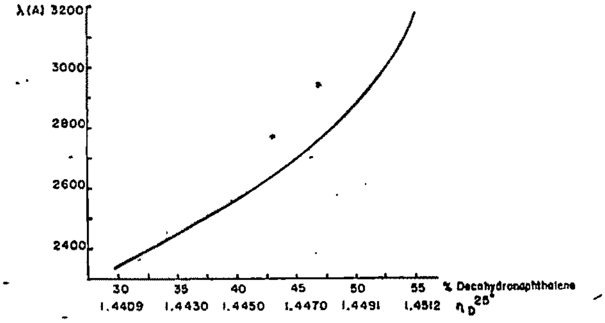

Fig. 2

which, with quartz chips, can be used in the region 2350–3000 A. The decahydronaphthalene and cyclohexane are purified by treatment with activated silica gel, either by passage through a column or by shaking with repeat charges. When thus purified, the cyclohexane in 1 cm. thickness will transmit, with a density less than 0·05, to 2250 A., the decahydronaphthalene to 2380 A.

A typical transmission curve for a filter designed to isolate the 2652 A. line of a medium-pressure mercury discharge tube is shown in Fig. 1. This filter employed quartz chips, graded between 0·6 and 0·8 mm., and was 5 cm. thick. The transmission curve was obtained on a small Hilger spectrograph. Fig. 2 indicates the composition of mixtures to provide filters giving a peak value at the wave-length indicated by the ordinate at 25° C. The $n_D^{25°}$ of the mixture is also given, as this is probably a more accurate indication of the correct mixture.

Above 3000 A., benzene–alcohol mixtures are to be preferred, as they provide filters of narrower band-width for the same thickness.

Studies are in progress as to the effect of particle size, optical parameters, etc., upon the peak transmission and band-width of these filters.

This work has been done in part under an American Cancer Society fellowship and grant recommended by the National Research Council Committee on Growth.

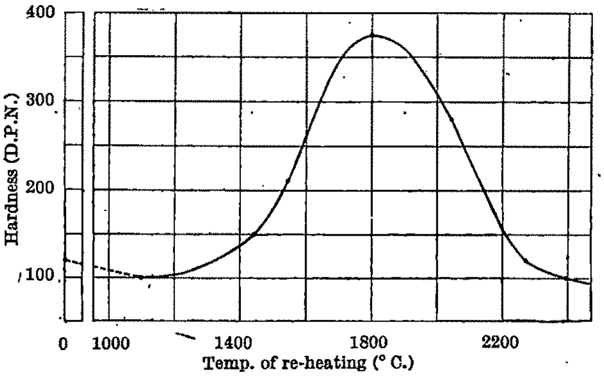
Annealing Temperature and Hardness of Tantalum

During experiments to determine the relationship between annealing temperature and hardness of tantalum after cold working, it was found that after a slight preliminary softening (temperatures up to 1,100° C.) the hardness rose steeply, reaching a maximum value after heating to 1,800° C., then falling again with higher temperatures.

The heating was carried out by passing a low-voltage current through the test piece in a vacuum of the order of 10^{-3}–10^{-4} mm. of mercury. When the current ceased to flow, the test piece cooled quickly by radiation. A typical curve is given in the accompanying figure.



The following points have been proved:

(*a*) Tantalum powder from three sources (American, Australian and German) compacted by pressing and sintering was cold worked (room temperature) by swaging and wire drawing and was quite ductile. On heating to 1,800° C. (as above) all materials became hard and brittle.

(*b*) The maximum value of hardness is found after heating to 1,800° C. irrespective of the initial amount of cold work.

(*c*) The hardness maximum appears to be a function of the initial amount of cold work, though no regular relationship has been found. The hardest material produced had a value 500 D.P.N.

(*d*) Hard tantalum becomes soft again if the heating is carried to 2,400° C. followed by quick cooling.

(*e*) Tantalum reheated to 2,400° C. and slowly cooled (7° C. per minute) to 1,100° C. is hard and brittle.

(*f*) X-ray diffraction patterns from tantalum in the soft and hard states indicate a body cubic structure in both cases. However, in the soft condition the lines are composed of distinct sharp spots, whereas in the hard state the lines are diffuse, and broader, and the spacing indicates an expanded lattice. No new lines were visible.

The most reasonable explanation of the above facts would appear to be that some gas molecules are absorbed even at the low pressure stated, and that these are held most tenaciously at 1,800° C. The increase in hardness of 300–400 units D.P.N. for such relatively low concentrations is, however, remarkable. The phenomenon is being further investigated.

Tryptophane as Precursor of Nicotinamide in Mammals

Tryptophane can replace nicotinamide in the nutrition of the growing rat[1] and when ingested increases the urinary elimination of nicotinamide derivatives of mammals and man[2–6]. The site and mechanism of this conversion of tryptophane into nicotinamide are unknown and form the subject of this investigation.

Biosynthesis of nicotinamide may occur in the mammalian tissue[7] or in the intestinal flora[8–12]. Bacteria of the *coli* type seem to be mainly responsible for the synthesis[13,14]. To find out whether the tryptophane conversion takes place in the tissues or the intestinal flora, rats kept on a mixed diet received 100 mgm. of *d,l*-tryptophane at three-day intervals alternatively either orally or parenterally. The increase in urinary nicotinamide methochloride elimination proved to be two to five times greater after oral than after parenteral administration, which is in accordance with findings of Schweigert and Pearson[3]. In other rats similarly fed, the increase in urinary nicotinamide methochloride output following tryptophane ingestion was measured before and during the daily administration of 1 gm. succinylsulphathiazole, with simultaneous bacteriological control of the fæces. When the fæcal *coli* and the spontaneous nicotinamide methochloride output were considerably reduced the increase in nicotinamide methochloride elimination caused by 100 mgm. of *d,l*-tryptophane was reduced to a fifth to a half the original increase. The results of both groups of experiments demonstrate at least that the intestinal flora is involved in the tryptophane conversion.

Of the known metabolites of tryptophane, kynurenic acid[15], kynurenine[16] and xanthurenic acid[17], none is a probable precursor of nicotinamide, because the first is an α-carboxylic acid, and nicotinic acid is a β-carboxylic acid, and the two others are only sparingly formed in the non-deficient animal. The urinary output of nicotinamide derivatives could not be increased by the ingestion of kynurenic acid[18]. Only 25–30 per cent of ingested tryptophane is eliminated as these metabolites.

When considering another possible way of degradation, we thought of the hitherto unproved formation of ornithine by reductive splitting off of the pyrrole nucleus. Ornithine was suggested as basis of the biosynthesis of nicotinic acid by Guggenheim[19].

To investigate this question, 24-hr. cultures of two *coli* strains isolated from rat fæces and known to synthesize nicotinamide when grown in an ammonium lactate medium[20] were inoculated and grown in this medium containing various concentrations of the following amino-acids : *l*(+) ornithine, *l*(+) arginine, *d,l*-glutamine, *d,l*-glutamic acid, *l*(+) citrulline, *l*(+) proline, *l*(+) leucine, *l*(−) isoleucine, *d,l*-valine, and *d,l*-tryptophane. Concentrations of $M/1,500$ to $M/1,000$ of the amino-acids proved to be most efficient. After 24 hr. incubation, the cultures were autoclaved and the growth assayed by titrating the acid formed with $N/10$ sodium hydroxide. Nicotinamide formed was measured microbiologically using *Lactobacillus arabinosus* in Barton-Wright[21] medium as a test object. Controls showed that none of the amino-acids used affected the acid formation by *Lactobacillus arabinosus*. The growth was increased by about 30–70 per cent by leucine, isoleucine, valine, citrulline, glutamic acid and tryptophane, but not, or less than 10 per cent, by the others. The formation of nicotinamide was, however, increased up to 4½ times by ornithine, by 50–70 per cent by glutamine and arginine when compared with the synthesis of nicotinamide in the controls. Of the other amino-acids, proline and tryptophane did not affect the relative nicotinamide production, while the others inhibited it. By a simultaneous assay using a *Leuconostoc mesenteroides* strain (kindly supplied by Dr. B. C. Johnson of the University of Illinois) which was much less sensitive to nicotinamide than to nicotinic acid, it was found that the derivative formed by the *coli* was almost exclusively nicotinamide.

These results show that ornithine can be utilized *in vitro* for the biosynthesis of nicotinamide by *coli*, and that arginine and glutamine, also with amino-groups in the δ-position and which probably can be converted into ornithine, have a similar effect. Whether ornithine can be formed from tryptophane has still to be proved. The fact that tryptophane does not increase the nicotinamide production by *coli* under the conditions of the experiment might be due to the inability of the *coli* to perform the tryptophane degradation. Other intestinal bacteria might be able to do this. Experiments using a mixed culture from the contents of a rat's cæcum showed an increase of nicotinamide production when tryptophane was added. This needs further investigation.

Ingestion of ornithine by rats did not increase the nicotinamide methochloride output, which might be explained by the quick utilization of this compound for protein formation. Perhaps the use of some possible intermediary between ornithine and nicotinamide may elucidate this point.

Composition and Structure of the Liver Cell in Pregnancy

It has been previously shown that the deoxyribonucleic acid content of the liver is independent of the protein content of the diet, while the protein, phospholipin and ribonucleic acid contents vary directly with the dietary protein intake[1].

Little is known regarding the changes occurring in the liver during pregnancy. Liver proteins are increased and more of the maternal protein is apportioned to the liver in pregnant rats than in non-pregnant controls[2]. The total nucleic acid content is considerably increased, both deoxyribonucleic acid and ribonucleic acid taking part in this rise[3].

It has now been found that in pregnant rats, during the third week of gestation, the deoxyribonucleic acid content of the liver (mgm. per liver) is considerably raised. Since the deoxyribonucleic acid content of the liver rises with increasing body weight, the changes in body weight during pregnancy have to be taken into account. The statistical analysis of the data (Dr. J. O. Irwin) shows that when adjusted for differences in maternal body weight (without fœtuses), the deoxyribonucleic acid content of the liver is significantly greater in pregnant than in non-pregnant rats, and, further, that the total quantity of deoxyribonucleic acid found in the liver during pregnancy closely corresponds to the sum of the maternal and fœtal body weights. This would signify that in pregnancy the liver has to fulfil its metabolic functions not only for the maternal body but also for the fœtuses. The rise in liver deoxyribonucleic acid is found in rats fed on the stock diet (group *A*), and in rats which had been fed on a protein-free diet for five days prior to the examination of the liver (group *B*).

The most remarkable of the changes occurring in the liver during pregnancy is, however, the rise in the ratio of ribonucleic to deoxyribonucleic acid. We found that this increased from 3·97 to 5·81 in group *A* (+46·5 per cent) and from 3·17 to 4·42 in group *B* (+ 39·5 per cent). It is known[1] that the changes in the ratio of ribonucleic to deoxyribonucleic acid due to variations in the dietary protein intake are accompanied by corresponding changes of approximately the same magnitude in the protein to deoxyribonucleic acid and phospholipin to deoxyribonucleic acid ratios. This also is true for pregnant rats; but in addition to the dietary variations of all three ratios, there is in pregnancy a specific rise in the ratio of ribonucleic to deoxyribonucleic acid, with inconsistent and relatively small changes in the other two ratios. Thus in group *A*, the protein to deoxyribonucleic acid ratio of the pregnant rats was only 9 per cent higher than that of the non-pregnant controls, while the phospholipin to deoxyribonucleic acid ratio did not change significantly; in group *B* there was no significant change in the protein to deoxyribonucleic acid ratio, while the phospholipin to deoxyribonucleic acid ratio rose by 21 per cent in the pregnant rats. The magnitude of the rise of the ratio of ribonucleic to deoxyribonucleic acid above the values found in non-pregnant controls is positively correlated with the weight of the uterine contents.

The presence of these large amounts of ribonucleic acid in the liver cell during pregnancy has its histological counterpart in a great increase in cytoplasmic basophilia. This is particularly well seen as diffuse basophilia in the periportal area and, by means of Brachet's ribonuclease test, has been proved to be caused by ribonucleic acid.

The glycogen content of the livers in both dietary groups is very much decreased during pregnancy.

We wish to thank Dr. J. O. Irwin, who kindly carried out the statistical analysis of the deoxyribonucleic acid data. We are also indebted to the Medical Research Council for grants for scientific assistance and expenses (to H. W. K.).

Fluorescent Constituents of Liver Lipid Extracts

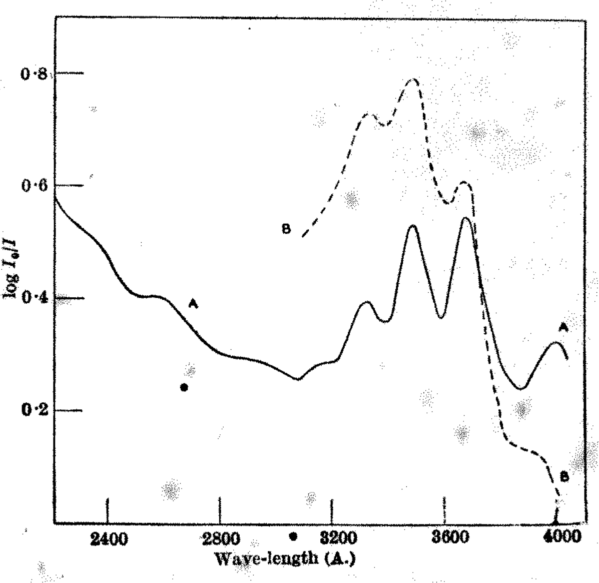
Penn and Kaplan[1] recently reported the preparation of concentrates exhibiting banded fluorescence spectra from acetone extracts of the livers of cancer patients. They have directed attention to the similarity between these spectra and the fluorescence spectrum of methylcholanthrene.

In continuation of earlier work[2], we have concentrated the fluorescent constituents of the non-saponifiable lipid-soluble material obtained from the livers of five cancerous and two non-cancerous individuals; but in none of our fractions have we been able to recognize any polynuclear aromatic hydrocarbons by ultra-violet spectrophotometry.

From two of the livers, fractions were obtained which possessed sharply banded absorption spectra between 3000 and 4000 A., and which exhibited an intense bluish-green fluorescence. The spectrum of one such fraction (Curve *A*) gave strong maxima at 3320, 3480 and 3680 A. in solution in *n*-heptane, together with a weaker maximum at 3990 A. The absence of intense absorption between 2000 and 3000 A. in curve *A* makes it improbable that these bands are associated with the presence of a condensed polynuclear aromatic hydrocarbon in the extract. The spectrum between 3200 and 3800 A. is closely similar to that reported by Zechmeister and Polgár[3] for material isolated from several plant sources, and tentatively identified by these investigators as iso-anhydro-vitamin A; the band at 3990 A. may be due to anhydro-vitamin A [4].

Iso-anhydro-vitamin A, prepared in our laboratory by the prolonged action of dry hydrogen chloride on a chloroform solution of vitamin A, gave the spectrum shown in Curve *B*, the location of the maxima being in good accord with those reported by Shantz, Cawley and Embree[4]. This product also exhibited a greenish-blue fluorescence, more stable and much more intense than that of vitamin A. Mixed with one of the fluorescent liver concentrates, it yielded a single fluorescent zone when adsorbed from hexane on a column of activated alumina.

These results indicate that at least part of the fluorescing material in the non-saponifiable fractions of liver lipids is probably associated closely with



vitamin A, although it is not clear whether the compound occurs in the liver as such or arises as a transformation product of vitamin A during the saponification and isolation process. The work of Edisbury and co-workers[5] on fish liver oils would suggest the latter may be the case.

Our concentrates were obtained by processes of solvent extraction, saponification, chromatographic adsorption and molecular distillation which will be described in detail elsewhere and which parallel quite closely those employed by Penn and Kaplan. The relationships between ultra-violet absorption spectra and fluorescence spectra are still not well understood; but the presence of fine structure in the near ultra-violet absorption of these fluorescing concentrates suggests the possibility that the banded fluorescent spectrum observed by Penn and Kaplan might have arisen from a similar substance.

The carcinogenic action of these liver extracts was negative when tested by subcutaneous injection in tricaprylin solution in mice. Since these extracts were essentially free from sterol, these observations do not contradict the findings of Hieger[6] concerning the carcinogenic activity of cholesterol fractions from similar source material.

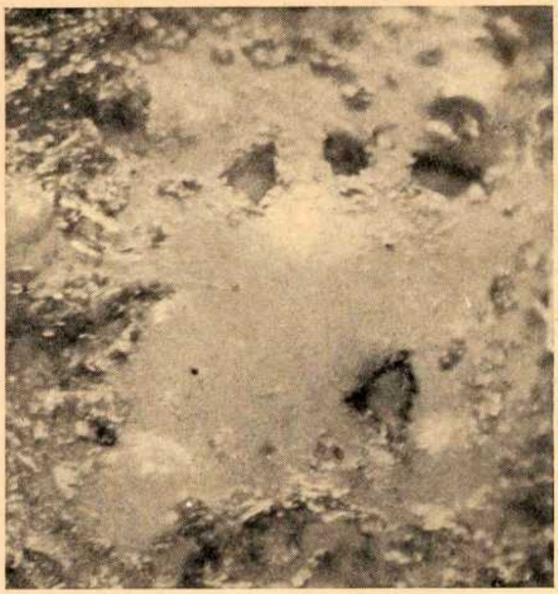
Tensile Stress as a Factor in Fern Phyllotaxis

ANATOMICAL investigations of the development of leaf primordia in the broad shield fern (*Dryopteris aristata* Druce)[1,2] have led me to the view that during growth each primordium sets up tangential tensile stress in the apical meristem above its axil. A further hypothesis is that the next primordium to be formed arises in that region of the apical cone in which tensile stress is minimal. It has been observed that meristematic tissue in regions subjected to tensile stress typically develops into parenchyma.

In his "Allgemeine Morphologie der Gewachse" (1868, p. 508), Hofmeister has advanced a hypothesis on the same general lines. He has suggested: (1) that the outer walls of the superficial cells of the shoot apex offer resistance to the lateral outgrowth of new organs (primordia); (2) that this resistance is not uniform over the growing point, new lateral organs appearing in regions of greatest elasticity; (3) that in proximity to the last formed primordia the superficial membrane, being already stretched, has minimal elasticity; (4) that a new primordium will appear in that position on the apex which lies farthest from the last formed primordia, that is, in the position of maximal elasticity and minimal tension. While Hofmeister's observation that new leaf primordia arise in the largest gap has been accepted by many investigators of phyllotaxis, his mechanical theory outlined above has received little support.

Already Snow and Snow[3,4] have shown that if the vegetative apex of several different flowering plants is incised, either transversely or longitudinally, the cuts typically gape. They have used this information to refute the view of Schuepp[5,6] and Priestley[7] that there is more rapid growth of the superficial than the internal tissue at the apex and hence that leaves arise as a result of compressive stress; but they have not directly suggested that the presence of tensile stress in the apical meristem may be a factor determining phyllotaxis (in conjunction with other factors).



DOWNWARD VIEW OF THE SHOOT APEX OF *Dryopteris aristata*. THE CIRCULAR PUNCTURE (TOP CENTRE) IS IN THE POSITION OF THE NEXT LEAF PRIMORDIUM TO BE FORMED. THE PUNCTURE IN THE AXILS OF THE PRIMORDIA (TOP LEFT AND RIGHT) ARE DISTENDED TANGENTIALLY, AS IS ALSO THAT OF THE PRIMORDIUM (BOTTOM RIGHT) BELOW. (× 40) (PHOTO. BY ERNEST ASHBY)

Preliminary studies of the distribution of growth in *D. aristata*, in specimens in which the apical region had been covered with a thin layer of lamp-black (applied as a suspension in 10 per cent gum arabic), support the hypotheses now advanced. Furthermore, when apices were laid bare and incised or punctured in different regions, positive evidence was obtained of the existence of tensile stress in and above the axil of each primordium, whereas stress was slight or absent in those regions in which the new primordia would arise (see accompanying photograph). The largest unoccupied space on the apical cone above the level of the last formed primordium, which, as Snow and Snow have pointed out, is the position in which the next leaf primordium will arise, is also that region of the apical meristem in which tensile stress is minimal. Why the imposition of tensile stress should affect the further development of the distinctive meristematic tissue at the shoot apex of ferns as it does is still obscure. The problem is an interesting one: its solution may be of considerable importance to our knowledge of morphogenetic processes.

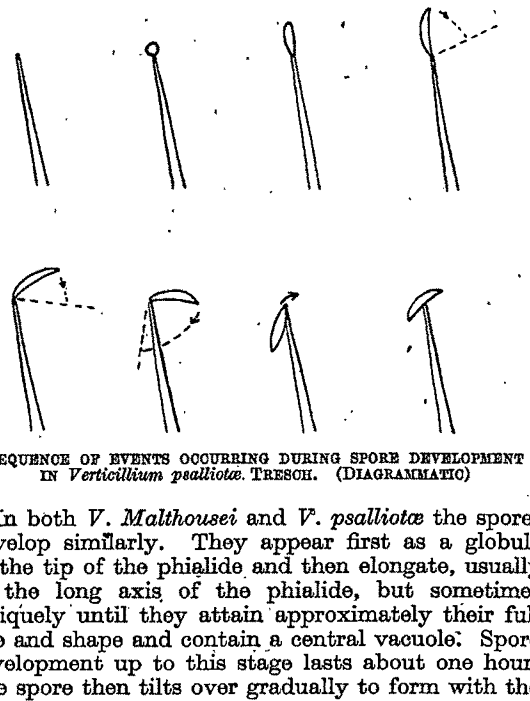
Passive Movements of Newly Formed Acrogenous Spores in *Verticillium* and Some Other Genera of the Hyphomycete Fungi

THE development of the spores in two species of *Verticillium*, namely, *V. Malthousei* Ware and *V. psalliotæ* Treschow, both parasitic on the cultivated mushroom *Psalliota* sp., was reported by Treschow[1] to be different. He observed the spores of *V. psalliotæ* lying transversely across the tips of the phialides on which they were developed. He concluded from this observation that the spores, which originated as a minute globule, grew out on either side perpendicular to the long axis of the phialide. He did not observe this transverse arrangement in *V. Malthousei* Ware, and neither did Ware[2] himself. It was, however, recorded in illustrations of this fungus by Atkins and Bulloch[3]. My own observations from time to time confirmed this record. More recently, I decided to compare the development of the spores in both these species under similar conditions, by continuous observation, using a moist chamber placed on slide cultures.



SEQUENCE OF EVENTS OCCURRING DURING SPORE DEVELOPMENT IN *Verticillium psalliotæ*. TRESCH. (DIAGRAMMATIC)

In both *V. Malthousei* and *V. psalliotæ* the spores develop similarly. They appear first as a globule at the tip of the phialide and then elongate, usually in the long axis of the phialide, but sometimes obliquely until they attain approximately their full size and shape and contain a central vacuole. Spore development up to this stage lasts about one hour. The spore then tilts over gradually to form with the long axis of the phialide an angle of about 120°. Eventually, it continues to tilt, but more rapidly, sometimes even suddenly, to an angle of 90° or less. Then, after a short interval, while remaining in the plane perpendicular to the long axis of the phialide, it suddenly describes an arc through an angle of 90°, but sometimes 180°, and then almost immediately slips across the tip of the phialide to lie in the transverse position recorded by Treschow for *V. psalliotæ* and by Atkins and Bulloch in their illustrations of sporing phialides of *V. Malthousei*. In agreement with these various authors, I observed that in *V. Malthousei* many spores developed in succession at the tip of the same phialide, the first formed becoming levered out of its horizontal position by the second spore, which followed later. These spores remained clustered together in a drop of fluid. In the case of *V. psalliotæ* I have not so far observed the formation of more than one spore at the tip of each phialide, except in an isolated instance where two were formed in succession.

These spore movements which I have described for two species of *Verticillium* explain the misinterpretation by Treschow of the transverse position of the spore relative to the phialide in *V. psalliotæ* and the uninterpreted illustrations of *V. Malthousei* by Atkins and Bulloch.

From preliminary observations of spore development in some other genera of Hyphomycetes bearing non-pedicellate spores, notably *Cylindrocarpon*, *Fusarium* and the *Clonostachys* form of *Gliocladium*, it seems that movements of a similar nature and occurring in the same sequence are not confined to the genus *Verticillium* but probably occur in many other genera. I have, however, observed movements of a different nature often occurring in *Cylindrocarpon* and in *Fusarium* as an alternative to those I have described.

Regulation of the Sodium–Potassium Ratio in Insects

THE variability of the sodium–potassium ratio in the cœlomic fluid of different species of insects and its association with the normal diet has been pointed out in previous papers[1,2]: the vegetarians having a high potassium concentration, the carnivorous insects a high sodium concentration in their cœlomic fluid.

In order to ascertain the nature of this association, the following hypotheses were tested: (1) The sodium–potassium ratio of the food might have a direct influence on the composition of the cœlomic fluid through lack of regulatory mechanisms in the insects. This possibility was suggested by the similarity between the sodium–potassium ratio of the cœlomic fluid and that of the diet; thus it is greater than 1 in the carnivorous insects and in animal fluids, less than 1 in vegetarian insects and in plant cells and saps. Carnivorous insect (*Calliphora erythrocephala*) and vegetarian insects (*Ephestia Kühniella*, *Pieris rapæ* and *Vanessa urticæ*) were raised from young to full-grown larvæ on diets with modified sodium–potassium ratio, all other factors being equal. This was done either by dialysing meat and wheat flour against solutions of various ionic

TABLE 1. NA/K REGULATION IN THE CŒLOMIC FLUID OF INSECTS

Insects and diets	Ions concentration in equiv./kgm.			
	In the diet		In cœlomic fluid	
	Na	K	Na	K
Calliphora erythrocephala (6 days on dialysed meat)	0·082	0·007	0·158	0·037
	0·010	0·111	0·083	0·040
Ephestia Kühniella (35 days on dialysed flour)	0·098	0·011	0·030	0·047
	0·098	0·011	0·027	0·056
	0·008	0·115	0·016	0·059
	0·008	0·115	—	0·065
Pieris rapæ (5 days on cabbage)	0·006	0·077	0·010	0·075
	0·006	0·077	0·013	0·074
	0·027	0·061	0·009	0·080
	0·027	0·061	0·010	0·077
Vanessa urticæ, 2 days on:				
Leaves	0·010	0·100	0·022	0·043
Leaves coated with NaCl	0·366	0·088	0·058	0·049
Leaves coated with KCl	0·010	0·700	0·021	0·080

ratios, or by cultivating cabbages on coastal and inland soils, and also by coating leaves with salt solutions.

From the results (Table 1), a regulatory mechanism capable of dealing with the ionic composition of both diets is therefore undoubtedly present in insects.

(2) Unsuspected constituents of the diet might have an influence on the regulatory mechanisms; this eventuality was studied by raising the same insect, *Tenebrio molitor*, on a vegetable diet (cabbage and flour) or on a powdered meat diet. After 3½ months, the sodium and potassium concentration in the cœlomic fluid of the two batches was unaffected, as shown in Table 2.

TABLE 2. INFLUENCE OF THE DIET ON THE CŒLOMIC FLUID COMPOSITION OF *Tenebrio molitor*

Diet (during 3½ months)	Ions concentration in equiv./l.	
	Na	K
Cabbage + wheat flour	0·091 0·090	0·040 0·042
Meat	0·097 0·096	0·042 0·042

From these experiments, we may conclude that the association observed between the sodium–potassium ratio in the cœlomic fluid and the diet is not the result of the chemical composition of the foodstuff acting during the actual life of a given insect. The ionic composition of the internal medium, as found now, is a species characteristic, maintained by mechanisms of mineral regulation.

Chick Embryos Surviving the Inoculation of an Equine Strain of Encephalomyelitis Virus

DURING routine work for the preparation on a big scale of embryo chick vaccine against equine encephalomyelitis, we observed that of 400 chick embryos 10–11 days old, inoculated with 0·05 ml. of a 20 per cent suspension of the infective brain tissue of guinea pig, there were sixty surviving embryos which continued development without inconvenience, judging by the trans-illumination control. Afterwards, and with the object of avoiding this effect, precautions were adopted to obtain the maximum mortality figures. Again, 400 chick embryos, 10–11 days old, were used and inoculated with the same virus strain with a dose of 0·1 ml. of a 30 per cent suspension of infective brain tissue of guinea pig taken from animals in the agonic period of the experimental encephalomyelitic infection. The effect was repeated; and about 10 per cent of the inoculated embryos behaved apparently like refractory animals, producing in due course well-shaped chicks.

In six other experiments, where 2,000 chick embryos, 9–12 days old, were used, it was found that if the experimental conditions were not changed, there were always chick embryos which, although having been duly inoculated, did not appear to be affected in their vitality after having received extraordinary amounts of active virus.

Further, experiments were also made, not only to check the observations, but also to study the possible influence of the age of the chick embryo, as well as the concentration of the virus at the dose used.

In all experiments we used a strain of virus of the encephalomyelitis equine West type maintained by passages in guinea pigs of 350–400 gm. weight, every 30 days, exclusively by the intralingual route.

Starting from brains extracted from guinea pigs in the agonic period, that is to say, 4½–5 days after inoculation, we made suspensions in buffer solutions at 7·2 pH with previous trituration and centrifugation of the infectious tissues. We chose, during the last assay, the dilution 10^{-1} at a dose of 0·1 ml. by the intra-alantoides route. This dose represents, on the basis of calculations made according to the recommendation of Reed and Muench[1], 500 L.D. (50) for guinea pigs by the intralingual route and 50 L.D. (50) for mice 28–30 days old by the intra-abdominal route; this last calculation is subject to the considerations quoted by Sabin and Olitsky[2] and Olitsky and Harford[3]. The age of the embryos we used was carefully controlled, and adequate controls were used for the inoculation technique, as well as for the maintenance of the chosen dose in contact with the embryonic tissues. Every inoculated embryo which died was extracted, and with previous trituration and dilution, inoculations into virgin guinea pigs and mice produced the encephalomyelitic infection.

Of 166 inoculated embryos, 22 which survived were tested and many of them born, presenting in all cases good vitality 96 hours after having received the corresponding doses.

Summing up our accumulated experience on the special behaviour of this virus strain of the encephalomyelitis equine West type, it is proved that it was not possible to obtain a regular mortality in chick embryos inoculated with a considerable dose of virus, and, further, that chick embryos younger than 9 days perish regularly due to the mortal action of the virus strain employed. Embryos older than 8 days, which have resisted alive the inoculation of a concentrated dilution of the strain studied, are comparatively less susceptible than guinea pigs and mice.

Nephrotoxic and Renotropic Effects of Lead on White Rats and its Prevention by *B.A.L.*

THERE have been many studies on renal injuries produced by lead, but so far as we are aware, mention has never been made of a renotropic effect of lead.

Daily administration to white rats of 2 c.c. of a 4·5 per cent lead acetate solution by stomach tube produced an increase of weight in the kidneys, which was already appreciable at the ninth day and persisted in rats poisoned throughout periods of three, five and twelve months (see table). No changes in blood pressure were observed throughout the experiments. Controls received 2 c.c. of a 4·5 per cent sodium acetate solution. Microscopic study of the kidneys of lead-treated animals showed degenerative lesions in the cells of Henle's loop and simultaneously signs of intense regeneration with large anomalous nuclei.

EFFECTS OF LEAD ACETATE ON THE WEIGHT OF THE KIDNEYS OF FEMALE WHITE RATS, CALCULATED PER 100 CM.² OF BODY SURFACE

Treatment	Duration of experiment (days)	Number of animals	Body-weight, average (gm.)	Kidneys weight, average (gm./100 cm.²)
Lead treated	9	10	114± 4·7*	0·552±0·019*
Controls	9	10	128± 5·4	0·395±0·012
Lead treated	150	8	181± 6·5	0·499±0·016
Controls	150	5	196±12·0	0·367±0·012
Lead treated	365	7	190±11·2	0·653±0·037
Uninephrectomy. Proteins and NaCl lead	90	6	175± 8·8	0·512±0·023
Uninephrectomy. Proteins and NaCl.	90	4	191± 9·9	0·398±0·023

* Standard error.

Hypophysectomy or adrenalectomy did not prevent the increase of weight and renal injury when lead salt solution was given to rats for a period of ten days.

Uninephrectomized rats fed on a standard diet and given lead for a period of six months had a tubular mass, as determined by diodrast excretion, 25 per cent greater than that of normal animals with both kidneys. Uninephrectomized controls on the same diet, but without lead, had a tubular mass 20 per cent below that of normal rats[1]. Uninephrectomized rats fed a diet rich in protein and sodium chloride and treated with lead throughout a period of three months had the same degree of hypertrophy of the tubular mass as those treated with lead and fed a standard diet.

The increase of kidney weight produced by giving the 4·5 per cent lead solution during ten days was almost completely prevented by injecting intraperitoneally twice daily 33 mgm. per kgm. of body-weight of a 2–3 dimercaptopropanol (*B.A.L.*) solution in distilled water. Microscopic study confirmed the results of the macroscopic observations.

It is worth mentioning that *B.A.L.* did not prevent the anæmia of lead poisoning in this species.

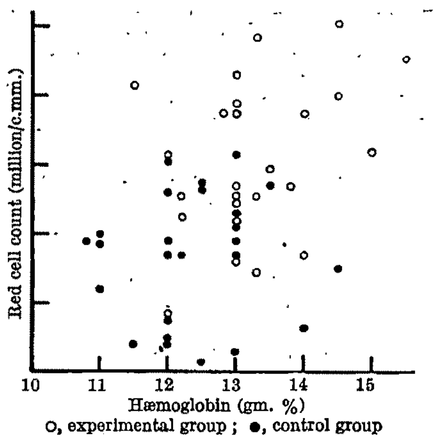
Induced Polycythæmia by *l*-Ascorbic Acid in Albino Mice

THE effect of *l*-ascorbic acid in increasing the number of red blood corpuscles has been studied in various laboratory animals[1] but hitherto not in mice. The present investigation was made to ascertain the action of the vitamin on the latter animal, taking into consideration, at the same time, the fact that there are many dietetic factors which affect the blood picture. Thus besides being properly fed on a diet consisting of cabbage and a mixture of cereal flour (8 parts) and whole milk powder (2 parts), the animals were given a salt mixture of iron, copper and cobalt (42, 55, 0·03 p.p.m. respectively[2]) and cod liver oil.



The animals, all male, were procured from the market and kept in the laboratory for one month before the experiment. Half received ascorbic acid and half served as control. Each mouse in the experimental group was fed daily 0·5 c.c. of a 4 per cent vitamin solution with a tuberculin syringe. The solution was prepared afresh every day. At the end of the third week, blood samples were taken from the tails of the animals. The red cell count was made with a Neubauer counting chamber after dilution with Hayem's solution. For hæmoglobin determination, the colorimetric acid-hæmatin method was employed.

EFFECT OF ASCORBIC ACID ON MEAN RED CELL COUNT AND HÆMOGLOBIN VALUE OF MALE ALBINO MICE

Duration of experiment, 3 weeks. Number of mice in each group, 25. Ascorbic acid fed to experimental group, 2 mgm./mouse/day

	Average initial body wt. (gm.)	Average final body wt. (gm.)	Mean red cell count (million/c.mm.)	Mean hæmoglobin (gm. per cent)
Control group	15·1±0·30	20·4±0·36	9·70±0·124	12·36±0·125
Experimental group	15·2±0·35	19·2±0·39	11·12±0·143	13·25±0·132
Difference			1·42 5·07	0·89 3·59

The results, as summarized in the accompanying table, show that there is a general increase in the average body weight and that the mean red cell count and hæmoglobin value of the 25 mice in the experimental group are higher than those of animals in the control group. When the values of the red cell count and hæmoglobin are presented simultaneously in a graph, the points for the two groups can be seen to have different centres of distribution. The significance of the data, however, was clearly shown by treating them statistically. By the *t*-value method[3], the probability that the difference is due to chance is found to be 0·001 in the case of hæmoglobin value and less than 0·001 in that of the red count.

DETECTION OF THE FREE AMINO-ACIDS OF PLANT CELLS BY PARTITION CHROMATOGRAPHY

By DR. C. E. DENT, W. STEPKA

AND

PROF. F. C. STEWARD

Departments of Botany and Pathology, University of Rochester, U.S.A.

ACCORDING to the classical and perhaps most generally accepted theory of protein synthesis in plants the amino-acids are intermediates in a process which proceeds after the pattern first outlined by Emil Fischer in the well-known polypeptide theory. On other views the amino-acids are regarded rather as the products of protein hydrolysis and as the form in which soluble nitrogen may be stored and eventually mobilized when synthesis proceeds[1]. Whichever of these views is held, it is a commonplace that free amino-acids are widespread in plants and they are known to exist dissolved in the cell sap, to which they contribute part of the buffering properties which titration curves reveal. This is neither the place nor the occasion to give the number of free amino-acids which have been identified in plant materials.

The application of the technique of partition chromatography on paper, devised originally by Consden, Gordon and Martin[2], to the investigation of the soluble nitrogen components of plants is a natural development particularly in view of the further reports of its successful applications in animal biology[3-6]. It is also of interest that a similar technique has been applied to other compounds such as sugars[7].

A note[8] in *Nature* by LaCour and Drew reports, apparently for the first time, the use of this technique on plant material and therefore calls for some special comment.

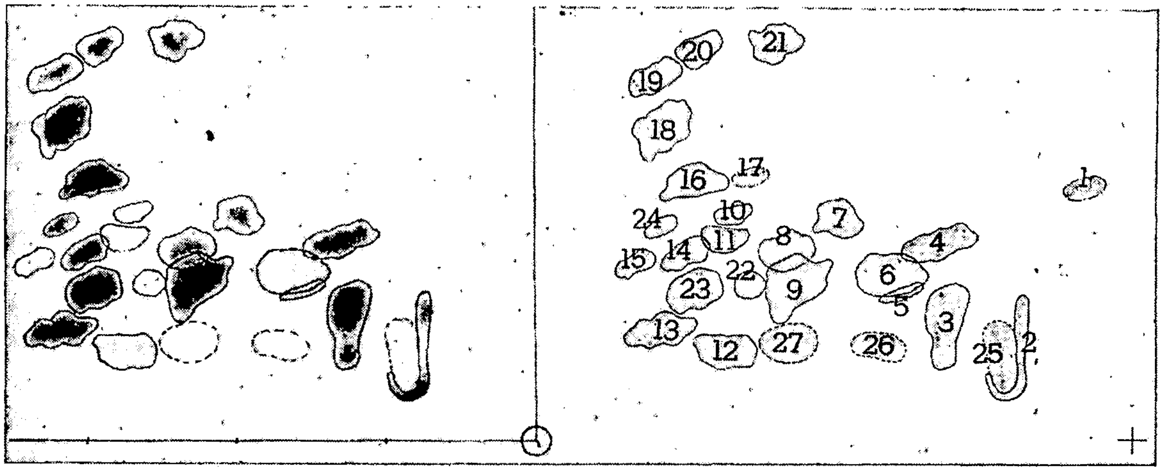
LaCour and Drew examined two types of plant materials: root-tips of *Trillium* and anthers of *Tradescantia* at various stages of development. The tissue was applied to filter paper strips in the form of a smear and the amino-acids were made to pass along the paper strip in phenol saturated with water, in accordance with the 'strip' or 'one-dimensional' technique familiar to users of the paper chromatographic method. On development of the chromatogram with the ninhydrin reagent LaCour and Drew obtained "two or more coloured bands indicating the presence of two or more free amino-acids".

It would indeed be somewhat surprising if plant cells contained as few amino-acids as suggested by the phrase "two or more". Although LaCour and Drew imply some casual relation between "nuclear activity" and the presence of amino-acids, their paper only allows one to conclude that two or more unidentified amino-acids are present in the crushed cells of *Trillium* root tips and the crushed anthers of *Tradescantia*. We therefore find it desirable to report the results of our own use of the paper chromatographic technique in the analysis of plant material. We do this, in advance of the publication of fuller details elsewhere, to show now the possibilities inherent in the method and also the biochemical range which studies of this kind involve.

The tissue at a cut potato surface is known to be capable of rapid metabolism in which protein synthesis from stored reserves of soluble nitrogen is a salient feature[1,9]. In moist air this tissue undergoes a recrudescence of growth which culminates in cell division and the formation of a meristem. In the form of thin disks (0·6 mm. or thinner) the tissues will accumulate salts from dilute solution and, without any inactive core of cells, will show evidence of great metabolic activity. We regarded, therefore, the potato tuber as particularly favourable material to study; first because the tissue is known to be rich in soluble nitrogen compounds, approximately two-thirds of the total nitrogen being soluble in alcohol; secondly, because of its known ability, under specified conditions, to synthesize protein at the expense of these reserves; thirdly, because of the known ability of the cells to grow and divide[10].

Briefly, we have established the following facts. The basic technique of paper chromatography is applicable to extracts of the soluble nitrogen of potato tissue under conditions which we shall specify exactly in a later communication. The amino-acids are best extracted in cold 70–80 per cent alcohol, giving a protein-free solution. The alcohol extracts are evaporated to dryness under reduced pressure without the use of heat and then are redissolved in water to give a solution which contains 10 mgm. of nitrogen per ml. For the chromatography an aliquot of extract containing approximately 50 μgm. of nitrogen (that is, 5 μl. of the solution) is normally used. The amino-acids on the paper square move for approximately thirty hours in phenol saturated with water, then the paper is dried. Afterwards the amino-acids move for approximately another thirty hours in a collidine (2–4–6 trimethyl pyridine)-lutidine (2–4 dimethyl pyridine) mixture (1 : 1 by volume) freshly equilibrated at the working temperature with the same volume of water. We then obtain a chromatogram (see accompanying illustration) which shows within a square of paper approximately 35 cm. by 45 cm. about twenty-four well-defined spots giving typical ninhydrin reactions. In addition there are at least three as yet unidentified constituents which appear yellow on the paper. By this means, positive and, we believe, unequivocable identification has been achieved of twenty-one amino-acids as normal constituents of the alcohol-soluble nitrogen of potato tuber tissue and three more still await final identification. So far as we are aware, this is the first systematic application of this relatively new technique to plant material, and some of the amino-acids thus identified will be reported for the first time to be present free in potato tissue and in plants.

A list of amino-acids (in the approximate order in which they are spread on the paper) which we have positively identified in the cold alcohol extract is as follows: cystine, aspartic and glutamic acids, serine, glycine, asparagine, threonine, alanine, glutamine, α-amino-*n*-butyric acid, histidine, arginine, lysine, methionine sulphoxide, proline, valine, methionine, isoleucine, phenylalanine, tryptophane and tryosine. Amino-acids which are still subject to investigation and confirmation or which are present in minimal amounts are: β-alanine or citrulline, and two distinct amino-acids near the position occupied by proline on the paper. The two latter substances have been seen by one of us (C. E. D.) in animal material and, therefore, they seem to be of general distribution in Nature. The possible presence of ornithine is still under investigation as there is some



A *B*

A. Two-dimensional paper chromatogram of alcoholic extract of potato tissue applied within the circle shown: direction of movement in phenol shown horizontally, movement in collidine-lutidine vertically. For the purpose of this photograph 150 μgm. of nitrogen were used: this larger amount reveals the relatively weak spots, although it tends to cause overlapping of some of the stronger ones. Using still larger amounts has revealed two constituents not shown here. Before photographing the original chromatogram each distinct spot was ringed with pencil. The photograph does not give a true rendering of the relative intensities of the spots, since it was necessary to 'print-in' certain areas to increase their density. *B* is a key to *A* prepared from a tracing from the original, but also showing the location of methionine and cystine as they are revealed after the extract is treated with H_2O_2. The identified substances are: 1, cysteic acid from cystine; 2, aspartic acid; 3, glutamic acid; 4, serine; 5, glycine; 6, asparagine, which gives a brown ninhydrin reaction; 7, threonine; 8, alanine; 9, glutamine; 10, α-amino-*n*-butyric acid; 11, histidine; 12, lysine; 13, arginine; 14, methionine sulphoxide; 15, proline which, owing to yellow ninhydrin reaction, does not show well in the photograph; 16, valine; 17, methionine sulphone from methionine which when unoxidized is normally obscured by the leucines at position 18; 18, isoleucine (leucine also occupies this position, but an independent method shows the predominance in these extracts of isoleucine); 19, phenylalanine; 20, tryptophane; 21, tyrosine., The as yet unidentified substances are: 22, probably β-alanine, although the position is also occupied by citrulline; 23, an unidentified amino-acid occurring in quantity; 24, an unidentified amino-acid occurring in small amounts; 25, 26, and 27 are unidentified substances of entirely unknown nature which appear as yellow areas on the chromatogram. These interesting substances are generally distributed in Nature, for example, large quantities have been found in normal blood and urine. The substance at position 25 characteristically distorts the spot due to aspartic acid at position 2.

difficulty in detecting it in presence of lysine. We do not claim to have exhausted the possibilities inherent in the method, but we do suggest that these are scarcely evident from the earlier statement by LaCour and Drew.

The mere list of amino-acids, coupled with our semi-quantitative observations, presents at the outset some interesting features. The preponderance of isoleucine over leucine (which we have not yet found) is surprising. Cystine and methionine require special procedure to demonstrate their presence[4] and although they have both been clearly seen they are by no means as conspicuous in the chromatograms as might have been expected. Hydroxyproline has not yet been positively detected. Glutathione can be revealed by the method but has not been seen in the chromatograms. α-Amino-*n*-butyric acid is present only in traces, and in accordance with the previous claim for its presence in blood and urine[6] it is suggested that it is more likely to be a breakdown product of an amino-acid (such as methionine) than an intermediary of protein synthesis.

Under conditions in which protein synthesis is known to occur in potato disks we have been able to show that many of these amino-acids decrease in amount to such an extent as to be no longer detectable in the chromatograms. Others, however, persist throughout in relatively large amounts, for example, glutamine and asparagine, glutamic and aspartic acids, and this is particularly suggestive in relation to the view[1] that in protein synthesis the soluble nitrogen may be drawn from a variety of stored amino-acids but is canalized through the system glutamine $\rightleftharpoons$ glutamic acid en route to protein.

We believe that the technique, in the form in which we have used it, opens a new chapter in the study of nitrogen metabolism in plants. However, the method will only be profitable if it is used in ways which utilize its remarkable selectivity. If the identity of a particular amino-acid cannot be established critically by matching against standards consisting of known amino-acids and by such specific tests as may be carried out either on the paper or on the amino-acid extracted from the chromatogram, the method of Polson, Mosley and Wyckoff[11], using electron defraction, offers other means of approach. It should also be noted that these authors claim to have used the paper chromatogram technique in a more quantitative manner after extracting the product of the ninhydrin reaction in acetone for subsequent measurement in a colorimeter.

Our own experiments will be reported in detail elsewhere, but it is already evident that the method enables one to detect the presence of a large number of amino-acids in plant cells and to reveal both qualitatively and quantitatively the changes which occur when cells, like those of the potato, embark upon protein synthesis and upon the kind of metabolism which normally culminates in cell division. It is true that the alcohol extracts do not localize the amino-acids in any particular cellular inclusion, and it will be necessary to find other means to demonstrate their distribution within the cell.

ARMY EDUCATION COURSES: PREPARATION FOR MARRIAGE

IN response to the great interest in family problems shown by students at the Command School, the General Officer Commanding, London District, sought leave to hold courses in "Preparation for Marriage" for Army personnel. Permission to hold such courses was granted by the War Office on condition that they should be looked upon as experimental and that attendance should be purely voluntary. Three such courses were held at the Command School, London District, during the summer this year, each of three days duration. The lecturing staff was provided by the National Marriage Guidance Council. In all cases the students were of mixed sex: at one of the courses men and women of all ranks attended together; for the others, officers and other ranks were divided into separate groups. The syllabus was planned to cover the sociology of marriage and the family, biology of sex and reproduction, sexual psychology and ethics, marriage and its adjustments, the emotional development of the child and the adolescent, parentcraft and homecraft. The speakers were Dr. D. Mace, Dr. Edward Griffiths, Dr. Gilbert Russell, Dr. Ethel Dukes, Mrs. Marjorie Hume and Mrs. Vera Mace. A special feature of each of the courses was a 'brains trust' consisting of all the speakers, who dealt at considerable length with each question. The questions themselves reflected a high level of frank and sincere inquiry.

In his report on these courses the General Officer Commanding, London District, is of the opinion that they were a distinct success. There was much evidence, he states, that they were appreciated by the students, who took the subject-matter as being long overdue, welcome and ordinary. As a result of this experiment, he recommends that further courses should be held in the London District, and that the holding of similar ones in other parts of the country should be considered. He also expresses himself as being in favour of permitting certain non-Service people to attend such courses, so that engaged and newly married couples might jointly take part in them. Special courses, he considers, should be held for married families in the Regular Army; and for the Roman Catholics separate arrangements should be made. It was generally agreed that the time allotted to these courses should be extended from three to four days.

It is stated that the Archbishop of Canterbury and the former Secretary of State for War regard these experimental courses as important preliminaries to Army-wide consideration of this vital subject. There would seem to be every justification for holding further ones and for widening their scope. These first courses were attended by carefully selected students who were engaged to be married, married, or sincerely interested; their ages tended to be higher than that of average Service personnel. Even so, there must be large numbers of similar men and women in the Services who would be glad to avail themselves of such valuable information and advice. Yet to restrict these courses on preparation for marriage to such students alone would be severely to limit the usefulness of what promises to become a most valuable branch of the educational service. For it is well known that in all the Services interest in sex and in personal relationships associated with sex runs at a very high level, while the temptations of physical gratification in surroundings away from home-circles are strongly intensified. The high incidence of venereal disease among members of the Forces is further evidence, not only of a medical and moral problem of serious dimensions, but also of the urgent need for a widely extended educational and advisory service which would have as its object the fostering of happy and harmonious family life.

To provide speakers with suitable training and outlook for such a service would at first throw a serious strain upon the National Marriage Guidance Council as well as upon the other voluntary organisations who are interested in sexual problems and family life. After a time, however, it should be possible for the Services to develop their own special educational and advisory staff. The preliminary courses also revealed a great need for a good supply of the right kind of books.

R. WEATHERALL

PHYSICS AND THE STEEL INDUSTRY

NEW LABORATORIES OF THE BRITISH IRON AND STEEL RESEARCH ASSOCIATION

THE laboratories of the Physics Department of the British Iron and Steel Research Association were officially opened by Lord Rayleigh on October 22. They are at 140 Battersea Park Road, London, under the charge of Mr. M. W. Thring, with a scientific staff numbering between forty and fifty. This is the second laboratory to be opened by the Association since its formation in 1945, the South Wales establishment having been opened on July 3 (see *Nature*, July 19, p. 100). The purpose of these laboratories is to enable the Association to carry out its function of supplementing and 'backing up' the great volume of research carried on by individual firms within the iron and steel industry. Before the formation of the Association, Corrosion Laboratories at Birmingham and the Marine Biology Laboratories at Millport (Scotland) were already in existence; experimental open hearth and blast furnaces have been constructed by the Association at Stoke-on-Trent, and plans are well advanced for the establishment of a metal-flow research station at Sheffield, which will complete the Association's immediate plans for the establishment of its own research stations.

Mr. G. H. Latham, president of the Association, presided at the informal lunch which marked the opening of the Physics Laboratories, when Lord Rayleigh spoke of the opportunities for physicists in the metallurgical field. Lord Rayleigh recalled discussions with Prof. Max Planck, Prof. H. L. Callendar, Sir Charles Parsons and others on the subject, and commented on the possibilities before the physicist in connexion with pyrometry, continuous casting, heat-resistant alloys and other such subjects. He commented on the increased organisation behind modern research, and "the great contributions to science and technology" that such organisation could make possible. Research had become a career, as a gathering such as that one demonstrated, and it was with pride and pleasure that he declared the Physics Laboratories open.

Sir Edward Appleton, secretary of the Department of Scientific and Industrial Research, spoke briefly and wittily in wishing that the work of the staff might be "exciting as well as fruitful and productive. . . . Your industry abounds with opportunity for the physicist", he said. "It was Isaac Newton himself who first posed the theoretical problem of elucidating the strength of materials—of explaining why the contiguous parts of a solid stick together, and that problem still gives people something to think about even to-day." He paid a warm tribute to Sir William Larke's zealous and selfless work for industrial research. "Although the Research Association is in itself youthful", he said, "the research spirit has for many years been alive in the iron and steel industry, and it must be gratifying to the pioneers to see the steady development of the central research organisation under the vigorous leadership of your council and your director, Sir Charles Goodeve."

Mr. D. A. Oliver, head of the research department of the B.S.A. group of companies, spoke on behalf of the Council of the Association. Emphasizing the close relations between fundamental physics and the steel industry, he instanced Dr. Schofield's work on the quick-immersion thermocouple, and work at the Association's laboratories on lead sulphide cells, aerodynamic flow through models, spectroscopy and X-ray crystallography. He laid great stress on the close relations between the Association, industry, the universities and other research organisations.

After lunch the guests proceeded to an inspection of the new laboratories. These are disposed on two floors of a factory building, and comprise some 14,000 sq. ft. of laboratory and office space. Their equipment includes a 50-kW. output high-frequency induction furnace, X-ray diffraction apparatus, a 3-in. aperture black-body furnace (designed and built at the laboratories) for use up to 1,700° C. for calibration of pyrometers, and a complement of laboratory and steelworks equipment.

The arrangement of the Physics Department is based on a plan approved by the governing council of the Association in 1946, which envisaged three main functions for the Department. These are: (1) to keep in touch with the advances of physical science with a view to possible application in the iron and steel industry; (2) to carry out research into the more fundamental physical problems connected with the work of the Association; (3) to carry out on behalf of the various divisions of the Association, research and development in fields of physics which are common to more than one division.

The Department may therefore be described as a 'horizontal' department in the Association's organisation, carrying out fundamental research to assist any or all of the six divisions under which the bulk of the work is organised. These six 'vertical' divisions correspond to the main divisions within the iron and steel industry, and are largely autonomous in operation. It is therefore an additional function of the 'horizontal' departments to assist in maintaining liaison between the divisions.

In implementing this programme two guiding principles have been adopted. (i) Experimental work should be backed up by theory wherever possible in order to avoid laborious testing of every combination of conditions ('long-shelf' research). (ii) The use of similarity theory can greatly enhance the value of a research laboratory by enabling it to test on a fundamental scale the key laws underlying complex industrial processes. This is particularly true in the iron and steel industry, where processes are too involved to permit the reduction of conditions to a form which can be solved by physical measurements of the required coefficients and mathematical solution of the corresponding differential equations.

These considerations have led to the division of the work of the Department into five broad categories, each organised under a section with a separate laboratory and office accommodation in the Department's laboratories. The sections are general physics, instruments, heat and thermodynamics, aerodynamics and mathematics. Guests inspecting the laboratories were able to see work in progress in each section, organised on the following lines.

General Physics Section. This is concerned with the state of the physical properties of steel and the metals used in steelmaking, and the interrelations between these properties. In order to avoid overlapping existing programmes, this field has been narrowed by the choice of bulk rather than surface properties, and by an emphasis in the direction of the properties of iron and steel above 1,200° C., that is, in a temperature range concerned rather with manufacture than with use. Work on continuous casting, in so far as it is concerned with experiments of heat transfer and plastic flow and with models of commercial processes, is being carried out by the General Physics Section, which in addition to its main laboratory has an X-ray laboratory and dark rooms.

Instruments Section. This is concerned with the large and increasing use of instruments in the steel industry. Recent developments in instrument design have raised new possibilities, and a part of the work of the Instrument Section is to bring together the instrument industry and the iron and steel industry in improving the supply and application of existing instruments. Its other main line of work is to develop new instruments, and work is proceeding in connexion with the measurement of the tension of wire in the process of drawing, a remote-reading electrical pressure meter for furnace pressures, and new developments in automatic temperature and radiation recording.

Heat and Thermodynamics Section. Problems of radiation, temperature measurement and heat transfer, which are of vital importance to the steel industry, are dealt with in this Section, which has a high-temperature laboratory in addition to its main laboratory. The Section is working on projects concerned with the development of methods for measuring the thermal properties of flames in furnaces, the exact assessment of the properties of radiation pyrometers and the development of a black-body furnace for their calibration, and the development of improved methods for surface temperature measurement.

Aerodynamics Section. This Section is concerned with all problems of flow, whether of gas in furnace systems or of liquids such as molten steel, slag and iron, and granulated solids. Such work is largely carried out by means of models, such as those used to investigate the flow of gases in an open-hearth furnace or the action of air-jets on the steel in a side-blown converter. The first problem in such cases is to determine which physical properties govern the process, and hence what is the correct similarity criterion which governs the time-scale of the model after the dimensional scale has been fixed by considerations of convenience.

Mathematics Section. A Section to deal with mathematical investigations has been introduced to ensure that problems which are examined experimentally will be dealt with also in terms of theory. It has already been found that more projects are coming along for calculation than can be dealt with by the number of staff originally planned. Among such problems are the heat transfer in continuous casting, the effect of oxygen on the thermodynamics of the blast furnace, the statics of furnace roofs when made with basic bricks, heat transfer in immersion pyrometers and in furnace systems, and the thermodynamics of the Bessemer converter.

There is also provision at the Physics Department's laboratories for a laboratory for the Association's Chemistry Department, and one for the Steelmaking Division. The former is devoted to investigations into the fundamental thermodynamic and kinetic aspects of the behaviour of iron and other elements during the process of iron and steel making. Dr. F. D. Richardson is in charge of this Department. The Steelmaking Division (under Dr. A. H. Leckie) carries out at Battersea work connected with instruments and process chemistry. In this connexion guests at the opening were able to inspect a mobile laboratory for use in steel works, which, mounted on an ex-army lorry chassis, has been designed by the Steel-making Division and assembled at the Physics Laboratories.

MARKET RESEARCH

THE importance to the manufacturer of acquiring accurate knowledge of his market is now becoming generally recognized. Should there have been any residual doubts, they were rapidly dispelled at the conference on market research conducted by the Manchester Joint Research Council on October 22, when the following papers were presented: "The Technique and Applications of Market Research", by Mr. O. W. Roskill (senior partner, O. W. Roskill, Industrial Consultants), "The Investigation of Trends of Consumer Tastes", by Mr. L. R. England (chief research officer, "Mass Observation"), and "Market Research and the Seller", by Mr. D. S. F. Vernon (Calico Printers' Association, Ltd.).

Mr. Vernon directed attention to influences such as machine production and increased mobility which were at work in the nineteenth century and which had the result of separating the producer from the consumer: "It is to bridge the gap between producer and consumer and appreciate more clearly 'consumer preference' (consumer requirements) that a scientific study of these factors has come to the fore under the label of Market Research". The other speakers noted the remarkable lack of knowledge of their own markets which was displayed by many manufacturers, even the efficient ones; and interesting examples were given by Mr. England and the other speakers of astonishing misconceptions as to the strength (or weakness) of customers' preference for a particular product.

In describing the technique of market surveys, Mr. Roskill observed four main avenues of investigation calculated to facilitate the establishment of the manufacturer's sales plan: the division of consumption into the separate uses for the goods in question, a survey of the factors affecting demand, an analysis of the channels of distribution and a knowledge of competition.

As might well be expected from a conference taking place in Lancashire, the treatment of the subject of market research was by no means confined to its relationship with consumable goods. In particular Mr. Vernon was concerned with the importance of investigations of textile markets, where the product is not one which is packed at the factory ready for final consumption, but a fabric which may be used for a variety of purposes. Similarly, Mr. Roskill devoted considerable attention to the technique of market research in relation to producer goods, and it is refreshing to note his emphasis upon the marketing problems which confront those manufacturers who are not concerned with the final retail consumer, but as sellers of semi-finished material, machine tools and other forms of industrial equipment are involved as links in a long chain of manufacture. In consequence, any analysis of the factors affecting the demand for their products cannot be limited to one immediate customer, but may involve an investigation extending into industries one, two, or even three times removed from the industry immediately under survey.

An aspect of market research which might perhaps have been elaborated with profit is the extent to which the manufacturer, having been presented with an analysis of his market, could venture to mould the demand to correspond with his manufacturing conditions. In so far as the market survey discloses the reasons for the preferences of customers, it should be possible to make some estimate of the risks involved in persuading them to accept articles which do not entirely conform to their tastes and prejudices, but which present advantages from the manufacturing point of view. The problem is one which is exercising the minds of manufacturers to-day, particularly those concerned with export markets, and invaluable guidance would be given to them if it were possible to assess the probable reactions of foreign customers, for example, to a policy of greater standardization directed towards the reduction of manufacturing costs by increasing the length of runs on relatively few models.

PROBLEMS OF SOIL AND LAND CLASSIFICATION

THE newly formed British Society of Soil Science held its first conference during September 26–29 in Oxford; the principal topic of discussion centred on problems of soil and land classification.

The first session was devoted to the problems of soil classification, which fall into two categories: how far can soils, which show continuous gradations from one type to another, be divided into types with sufficiently sharply defined differences, so that a soil map can be made of a whole region; and whether the soil map should be made without any reference to the use to which it will be put. Mr. C. G. T. Morison (Oxford), Prof. G. W. Robinson (Bangor) and Prof. S. W. Wooldridge (London) read papers at this session and many members took part in the discussion.

The first two speakers were concerned with mapping soils by 'associations'. In any one region the soil will vary because, as Prof. Robinson put it, the soil is a passive agent of variable constitution acted upon by climate, vegetation and so forth, and these vary over the region. In many regions most of these active agents remain fairly constant with only one or two changing appreciably. Such an area can then be mapped, not by mapping the individual patches of the different kinds of soils present, patch by patch, but by indicating that all variations occur in regular succession between certain types. This includes both the ordinary method of mapping associations and Milne's method of recognizing catenas. The principle is easily applied if only one soil-forming factor is varying appreciably over the region, but becomes more difficult to apply if several are varying. Prof. Wooldridge discussed the more specific problem of the value of recognizing the geomorphological age of the surface on which the soil is formed, and illustrated the points he made by discussing the chalk surfaces of southern England.

The second session was devoted to problems of land classification. Here the problems are of immediate interest to the community, since they concern the conflicting demands upon the use of land for buildings, mineral exploitation and food production. Dr. E. C. Willatts described some of the problems confronting the administrator who has to approve certain types of land use, developments and changes to ensure they are consistent with the policy laid down in the White Paper on "The Control of Land Use" (Cmd. 6537) and in subsequent legislation. By clearly stating the problems facing land planners, he hoped that soil surveyors and other people who had to assess the value of land would prepare their results in such a form that the administrator could easily understand and use them.

Dr. D. A. Osmond gave the definitions, adopted by the West Midland Group on Post-War Reconstruction and Planning, for classifying agricultural land into three categories of good, medium and poor on the basis of its inherent features of site and soil. Site involves the consideration of aspect, slope and elevation, while water-conditions, depth and texture are taken into account as soil factors. Using this simple classification, the major categories of agricultural land can be readily picked out. Eight western counties of England have been mapped on this basis. Because of the high farming on soils frequently of medium quality, market garden areas such as the Vale of Evesham, and some other districts, are included in sub-categories of good agricultural land.

Mr. F. R. Day (Oxford) then discussed criteria for judging the economic value of land for forestry. He showed that if the tree is to come to a proper height at maturity, or at a given age, there is an optimum curve relating its rate of growth with age for each species of tree in a region. Any falling off from this curve is due to some soil factor making the site less suited for the economic exploitation of that species. He illustrated these points by discussing the rate of growth of forest on thin or wet land, often considered suitable for forestry because unsuitable for agriculture, and showed that growth of many species is too slow for economic exploitation, even though initially the growth may be very rapid.

Finally, Mr. G. R. Clarke (Oxford) described the gravel survey of the London area, a survey undertaken to map the good, medium and indifferent agricultural soils overlying the gravel. The object was to see how far it would be possible to prevent the exploitation of the gravels under the best agricultural and market garden land and to continue their exploitation under the poorer soils. Unfortunately, as Prof. Wooldridge later pointed out, there are many different types of gravels, and some essential for making concrete only occur in sufficient quantity under some of the best agricultural land.

TUBERCULOSIS OF VOLES AND SHREWS

It is ten years since Dr. A. Q. Wells reported the presence in the wild vole (*Microtus agrestis*) of a murine type of tubercle bacillus; since then a good deal of work has been done upon this organism. Tuberculosis has been found also in the bank vole (*Clethrionomys glareolus*), the wood mouse (*Apodemus sylvaticus*) and the shrew (*Sorex araneus*), and the relationships of this murine type of tubercle bacillus to the bacilli which cause human and avian tuberculosis have been carefully studied. The present position of our knowledge of the problems raised by the discovery of this bacillus has now been ably stated by Dr. A. Q. Wells in a report entitled "The Murine Type of Tubercle Bacillus (The Vole Acid-Fast Bacillus)", to which Dr. A. H. T. Robb-Smith has contributed notes on the morphology of infection by the vole acid-fast bacillus.*

Illustrated by very clear photographs and by graphs and diagrams, this report is a valuable addition to the literature about tuberculosis. The structure, cultivation, antigenic structure, pathogenicity and other features of the vole bacillus are all discussed, and Wells concludes that the statement that the disease which it produces is tuberculosis "seems justified, in spite of the fact that tuberculosis as a disease of other wild animals in their natural habitat has not hitherto been found". It is not possible to separate the vole bacillus from the human or bovine bacilli tubercle by serological methods; animals infected with the vole bacillus are sensitive to human or bovine tuberculin, and animals infected with human or bovine tubercle bacilli are sensitive to a tuberculin prepared from the vole bacillus. The vole bacillus can, moreover, produce progressive disease of the animals which it can infect, and this disease is indistinguishable from that produced by human or bovine tubercle bacilli. The vole bacillus is therefore a third type of tubercle bacillus. One of the most valuable sections of this report discusses experiments which have been designed to find out whether experimental infection of laboratory animals with the vole bacillus will confer any degree of immunity to the human or bovine tubercle bacilli. The use of a vaccine prepared from the vole bacillus for the production of immunity in man is also described; and the instrument used for some of these experiments, which enables forty simultaneous punctures of the skin to be made, is described and illustrated. Wells discusses the results obtained and also the relative merits of B.C.G. vaccine and the vole bacillus vaccine. An evaluation of the results obtained can be made only by experts who have a wide experience of that kind of work. Those who are interested must read the report itself.

Dr. A. H. T. Robb-Smith's notes on the lesions produced by the vole bacillus and the excellent photographs of them with which he illustrates his notes are a worthy addition to the report. Everyone who is interested in the intricate problems presented by tuberculosis will be grateful for the inclusion in a single compact and well-written publication of so much information, together with the references to the literature which are relevant to it.

G. Lapage

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, November 17

Royal Physical Society of Edinburgh (at the Royal Scottish Geographical Society, Synod Hall, Castle Terrace, Edinburgh), at 5.15 p.m.—Dr. D. O. Morgan: "The Liver Fluke".

Tuesday, November 18

British Psychological Society, Industrial Section (at the London School of Hygiene and Tropical Medicine (Room 105), Keppel Street, London, W.C.1), at 1.10 p.m.—Mr. Elliott Jaques: "Methods of Changing Group Behaviour".

Chadwick Public Lecture (at the Royal Sanitary Institute, 90 Buckingham Palace Road, London, S.W.1), at 2.30 p.m.—Mr. G. A. R. Sheppard: "Modern Trends in Waterworks Practice" (Bossom Gift Lecture).*

Royal Society of Arts, Dominions and Colonies Section (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Dr. J. G. Malloch: "Scientific Research in Canada and its Links with Science in the United Kingdom" (Neil Matheson McWharrie Lecture).

Society of Chemical Industry, Agriculture Group (in the Physical Chemistry Lecture Theatre, Royal College of Science, Imperial Institute Road, London, S.W.7), at 2.30 p.m.—Dr. R. S. Cahn: "The Role of Chemistry in Recent Developments of Animal Insecticides".*

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5 p.m.—Rev. E. W. Smith: "The Ba-Ila Revisited".

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Sir Edward Salisbury, F.R.S.: "The Vegetation of the Chalk", 4, "The Woodlands of the Chalk".

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. G. C. L. Bertram: "Eugenics, Population Trends and the World's Resources".*

Physical Society, Low Temperature Group (joint meeting with the Chemical Engineering Group of the Society of Chemical Industry, at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. P. M. Schuftan: "A New Process for the Recovery of Ethylene from Coke-Oven Gas".

Society of Dyers and Colourists, Scottish Section (at St. Enoch Hotel, Glasgow), at 7 p.m.—Dr. A. Landolt: "Improvement of the Properties of Fibres and Dyeings by Treatment with Hydrophobic Melamine-Formaldehyde Compounds".

Wednesday, November 19

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Sir Ernest T. Fisk: "The Development of Sound Recording and Reproduction".

Royal Meteorological Society (at 49 Cromwell Road, South Kensington, London, S.W.7), at 5 p.m.—Scientific Papers.

Royal Microscopical Society (at B.M.A. House, Tavistock Square, London, W.C.1), at 5 p.m.—Communications on "Electron Microscope Studies of Tissues from High- and Low-Breast Cancer Strains of Mice" (to be introduced by Prof. R. D. Passey).

Royal Institute of Chemistry, London and South-Eastern Counties Section (at the Wellcome Research Institution, 183 Euston Road, London, N.W.1), at 6.30 p.m.—Annual General Meeting.

Society of Dyers and Colourists, Midlands Section (at the Victoria Station Hotel, Nottingham), at 7 p.m.—Dr. E. S. Paice: "Petroleum Chemistry as applied to Textiles".

Thursday, November 20

Royal Society (at Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Symposium on "The Results of the Heligoland Explosion" (to be opened by Dr. E. C. Bullard, F.R.S.); at 4.30 p.m.—Special General Meeting to consider the Annual Report of Council.

Chemical Society (in the Chemistry Lecture Theatre, The University, Liverpool), at 4.30 p.m.—Prof. H. W. Melville, F.R.S.: "The Chemistry of Ethylenic Polymers".

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—"Cross-Linking in Polymeric Systems" (other lectures on November 27, December 4 and 11).

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Report on "The Practical Training of Professional Electrical Engineers" (to be presented by Sir Arthur Fleming).

Chemical Society (joint meeting with the University College Scientific Society, in the University College, Hull), at 6 p.m.—Prof. A. C. Chibnall, F.R.S.: "The Structure of Proteins from the Viewpoint of the Chemist".

Women's Engineering Society, Manchester Branch (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Mr. W. Bosley: "The Cyclotron and Betatron".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Scientific Papers.

Friday, November 21

Institution of Electrical Engineers, Measurements Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Prof. J. Greig and Mr. H. Kayser: "Iron-Loss Measurement by A. C. Bridge and Calorimeter".

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Sir Alwyn Crow: "The Rocket as a Weapon of War in the British Forces" (Thomas Hawksley Lecture).

Royal Institute of Chemistry, London and South-Eastern Counties Section (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Mr. G. Taylor: Streatfeild Memorial Lecture.

Society of Dyers and Colourists, Manchester Section (joint meeting with the Textile Institute, in the Gas Department Showrooms, Town Hall Extension, Manchester), at 7 p.m.—Mr. C. P. Tattersfield: "The Effect of Physical Pretreatment on the Ease of Saponification of Cellulose Acetate Rayons and Films".

Chemical Society (in the Royal Technical College, Glasgow), at 7.15 p.m.—Prof. M. G. Evans, F.R.S.: "Electron Transfer Reactions".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. C. H. Desch, F.R.S.: "Recent Developments in the Steel Industry".

Saturday, November 22

Royal Institute of Chemistry, London and South-Eastern Counties Section (at Brighton Technical College, Brighton), at 6 p.m.—Mr. J. G. N. Gaskin: "The Examination of Questioned Documents".

Thursday, November 20—Friday, November 21

Institute of Physics (joint meeting of the Midland Group and the X-Ray Analysis Group, in the Temple Room, Imperial Hotel, Birmingham).—Conference on "The Structure and Physical Properties of Metals".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Chemistry up to B.Sc. standard—The Principal, Chelsea Polytechnic, Manresa Road, London, S.W.3 (November 22).

Principal Deputy Director and a Deputy Director (Research) in the Meteorological Office—The Under-Secretary of State, Air Ministry (S.2), Cornwall House, Waterloo Bridge Road, London, S.E.1 (November 30).

Lecturers in General Science, Geography, and Mathematics—The Secretary, University of London Institute of Education, Malet Street, London, W.C.1 (November 30).

Chair of Geography at Bedford College—The Academic Registrar, University of London, Senate House, London, W.C.1 (December 1).

Assistant Director (Development) in the Department of Atomic Energy, Risley, Lancs—The Ministry of Labour and National Service, Technical and Scientific Register, Room 699, York House, Kingsway, London, W.C.2, quoting F.898/47A (December 2).

Chair of Botany at Queen Mary College, and the Hildred Carlile Chair of Botany at Bedford College—The Academic Registrar, University of London, Senate House, London, W.C.1 (December 4).

Superintendent of the Engineering Division of the National Physical Laboratory in the Department of Scientific and Industrial Research—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2034 (December 4).

Fuel Engineer to undertake the investigation of problems associated with the use of turf in domestic and industrial consumer appliances—The Secretary, Bord na Mona, 28–30 Upper Pembroke Street, Dublin (December 6).

Educational Psychologist—The Secretary, The University, Edmund Street, Birmingham 3 (December 6).

Senior Principal Scientific Officer in the Royal Naval Scientific Service (in the first instance as Superintendent of the Royal Naval Physiological Laboratory, Gosport)—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2025 (December 8).

Principal Scientific Officers or Senior Scientific Officers in the Ministry of Supply, (*a*) at Headquarters in London for handling research work connected with high temperature alloys and materials for use in gas turbines and other engines, (*b*) at the Royal Aircraft Establishment, Farnborough, to undertake research and development work on light alloys used in aircraft production—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2032 (December 9).

Deputy to the Scientific Adviser to the Army Council—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2026 (December 10).

Chemist in the Endocrine Unit—The House Governor, London Hospital, Whitechapel, London, E.1.

Physicist or Metallurgist with X-ray crystallographic experience, and a Metallurgist, for research on the surfaces of metals and coatings—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1.

Senior Lecturer in Mathematics—The Principal, Chelsea Polytechnic, Manresa Road, London, S.W.3.

Lecturer in Bacteriology—The Registrar, The University, Reading.

Mathematical Physicist for the Theoretical Physics Branch of the Research Division—The National Research Council, Atomic Energy Project, Chalk River, Ont., Canada, quoting File 9–F.

Organic Chemist, a Radio or Electronic Engineer, and a Technical Assistant for general laboratory work—The Secretary, British Rubber Producers' Research Association, 19 Fenchurch Street, London, E.C.3.

Lecturer in Pharmacology—The Dean, College of the Pharmaceutical Society, 17 Bloomsbury Square, London, W.C.1.

Research Assistant in the Pomology Department—The Director, John Innes Horticultural Institution, Merton, London, S.W.19.

Lecturer in Physical Chemistry to Honours Degree standard—The Registrar, College of Technology, The Newarke, Leicester.

Lecturer in Mathematics—The Principal, Sir John Cass Technical Institute, Jewry Street, London, E.C.3.

Lecturer in Physiology—The Registrar, University College, Nottingham.

MASS EDUCATION AND INTERNATIONAL UNDERSTANDING

THE discussion on the United Nations Educational, Scientific and Cultural Organisation which took place at the British Association meeting at Dundee attracted a very small audience; no doubt this was due in part to the fact that the meeting clashed with other important and topical discussions; but a more important reason is the general lack of knowledge of the activities of the Organisation. Sir John Maud, it is true, headed members of the British co-operating body, and expounded most ably the aims of the Organisation; he believes it should attempt to instruct the peoples of the world on the realities of the situation, so that they can understand better the causes of peace and war and thus make the politicians' task of direction easier. He sees its task as primarily that of helping people to learn that they need one another, and to deepen their sense of social responsibility, thus pursuing much the line of thought in more general terms that Mr. Henry Stimson follows in his article in *Foreign Affairs* on "The Challenge to Americans". Prof. F. J. M. Stratton dealt with the relations of the Organisation with the international scientific unions, and other speakers in the discussion indicated the wide range of fascinating subjects with which it is already concerned. Its major activities have since been reviewed in a progress report by Dr. W. H. C. Laves, the deputy director, in the *United Nations Weekly Bulletin*. Already some 72 million dollars' worth of material has been collected by voluntary agencies, chiefly in the United States, under the Temporary International Council for Educational Reconstruction, and fifty sets of laboratory equipment have been collected for consignment to forty-one selected laboratories in five countries. Technical needs in the fields of the Press, radio and films have been surveyed in some eight or ten war-devastated countries. It is expected that a conference at Nanking will encourage a pilot project on fundamental education, for which the Organisation will provide an adviser; and consultant-advisers for pilot projects in the same field are also to be provided for the Governments of Haiti and Nyasaland. The Organisation is also vitally concerned with mobilizing social scientists throughout the world for an inquiry into the tensions affecting international understanding, and a preliminary outline on this study has been distributed to nearly five hundred workers in this field in twenty-nine countries. Preparations are under way for a conference on the social sciences in 1948.

The Organisation also participated in the meetings of the United Nations Sub-Commission on Freedom of Information and of the Press, and has prepared for the Economic and Social Council a study of the shortage and unequal distribution of newsprint and of the bearing of this on the freedom of the Press. Material is being collected through national sources for world lists of films on international understanding, fundamental education, agriculture, health and popularization of science and the arts. An International Scientific Commission called by the Organisation and the Government of Brazil, which met in Belem in September, discussed the establishment of an Institute of Hylean Research (see *Nature*, Sept. 27, p. 427).

A temporary science co-operation office has been set up in Rio de Janeiro and steps taken to establish an office in the Middle East. A third office, in the Far East, is being established this autumn. Several grants-in-aid have been made to scientific international bodies which are members of the International Council of Scientific Unions. The copyright problem is also being tackled, and assistance has been given in the award of fellowships provided by member States and organisations such as the American Chemical Society for the exchange of qualified personnel.

That the United Nations Educational, Scientific and Cultural Organisation may in such ways as this render great service to science is not to be doubted. The primary ideal on which the Organisation was founded—the free flow of ideas among men—is at the root of scientific advance also. But it should be recognized also that while the Organisation derived much of its original shape and confidence from the intellectuals of Europe, with the new morale among professional men and the clearer understanding of the political power inherent in cultural affairs which the experience of the War gave them, the real leverage of the Organisation in whatever it does must be the power of public opinion; and as Mr. Byron Dexter observes in *Foreign Affairs* (**25**, 388; 1947) the two requirements for the effective application of that force are technical efficiency and unremitting attention to the business in hand.

Dr. Laves' progress report gives promise that the director-general and his staff do, in fact, embody these virtues as they are designed to do, but neither his report nor the discussion at Dundee came to grips with the real issue that confronts the Organisation—the firm rejection by the U.S.S.R. of that primary freedom of information which is an inseparable part of freedom of speech and expression. Mr. Ritchie Calder, it is true, dealt at Dundee with the problem of securing the interest and support of the two thousand million peoples in the world, and maintained that this is only possible through the media of mass communication. The instruments of mass communication, though effective, can be very dangerous; and Mr. Calder estimated that if the Organisation were to have its own newspaper, film-studios and broadcasting stations, it would need an income of a billion dollars a year.

While that would appear to be outside the range of possibility for a considerable time to come, even if it be accepted as necessary or desirable, on the cultural side there are much more hopeful signs than in the political and economic field. The series of international conferences in so many branches of science, and other intellectual activity during the present year, bear witness to a remarkable yearning to override national frontiers, to confer and compare experience. A deep thirst for books and periodicals, for the exchange of dramatic works, films and music is evident to any traveller in Western or Eastern Europe. Mr. Kenneth Lindsay notes in *The Manchester Guardian* that most of those concerned in the rebuilding of European education and culture are anxious to leave political views in abeyance and to resume their specialist studies and scholarship in order to catch up with the last years of research and reading.

Mr. Lindsay points out that besides the old-established international societies reviving their work, there has been a wholly new set of conferences, designed to establish new societies, to build new bridges, and to weave new patterns of thought and culture. His travels have indicated that the vicissitudes of war have given even greater confidence in the values of European civilization and freedom of learning, while shaking the hold of political dogmas. In each country he found the same basic questions being faced: the preservation of standards in secondary schools; the proper approach to youth; the status, pay and freedom of the teacher; the quality of the administrator; the definition and function of a university in the twentieth century; and the supreme importance of adult education and democracy.

Admittedly, education has not kept pace with scientific, political and economic development. Except in one or two areas, the social sciences are backward all over Europe. But while reconstruction work is under way and the British Council, and more recently U.N.E.S.C.O., have repaired some deficiencies by sending technicians and specialists to British universities and Swiss and Swedish technical colleges, Mr. Lindsay pleads eloquently for fresh inspiration and leadership in the universities and among those who form the minds of the growing generation. It is the absence at the present time of European leadership, apart from a small group of thinkers and writers who can only meet each other with considerable difficulty, that Mr. Lindsay regards as the most sinister feature.

Is it possible that the United Nations Educational, Scientific and Cultural Organisation could meet this need, and at the same time boldly take up the challenge represented by Russian rejection of three out of the four freedoms of Franklin Roosevelt? The political and economic organs of the United Nations will not function effectively unless they are matched by the acceptance of some common values—values expressed in general terms which permeate the schools and universities, and above all those million undergraduates in European universities who are destined to influence so largely the next decades of European history. If the Organisation is wise enough to eschew undertakings such as the revision of text-books, which though admirable in theory are likely to prove sterile in practice and merely controversial, and to concentrate on fields such as mass education, the reconstruction of education in Europe, and scientific projects such as the exploration of the resources of the Hylean Amazon, it may do two things. It may secure the widespread support and understanding it needs for success, and doing so it may demonstrate that an edifice built on the four great pillars of freedom of speech and expression, freedom of religion, freedom from fear and freedom from want is more secure, spacious and satisfying than one based solely on the banishment of want.

There can be no more hopeful way of inducing those who remain outside U.N.E.S.C.O. to use the freedom and the shelter it offers and of thus at last creating one world community; but to succeed in this it is necessary to remember, as Mr. Ritchie Calder has pointed out, that the purpose of the Organisation lies not with the pedants, but with the peoples of the world. It may assist scientific workers, for example, to maintain the unrestricted pursuit of objective truth and the free exchange of ideas and knowledge; but the first duty of the Organisation is not in any such narrow or limited field. It is "to collaborate in the work of advancing mutual knowledge and understanding of peoples, through all means of mass communication"; not merely to increase and improve the means of communication between the thirty-five nations that have accepted the principles defined in the preamble of the Charter, but to use these means for the purpose of mutual understanding, and a true and more perfect knowledge of each others' lives. The measure of achievement of the United Nations Educational, Scientific and Cultural Organisation will depend not merely on the extent to which it enlists the support of men of science and other specialists, but above all on its success in discovering the idioms of the ordinary people and interpreting to them its aims, its plans and its achievements.

A DEVELOPMENT PLAN FOR UGANDA

A Development Plan for Uganda
By E. B. Worthington. Pp. xii+112. (Entebbe: Government Press, 1946.) 2*s*. 6*d*.

In no part of Britain's tropical empire is research into the available agricultural and commercial possibilities more likely to reward the investment of capital and labour than in the Uganda Protectorate. Focal position within Africa, easily manageable size, reliability of rainfall, and—by African standards—a fair degree of soil fertility are among its physical assets; while, in regard to the availability of suitable labour, the intelligence and aptitude of its Bantu and Hamitic communities are well esteemed.

It was inevitable, no doubt, because of the nature of Dr. Worthington's report, based as it is on a comprehensive yet highly summarized statement of the physical resources of the Protectorate, that little space could be spared for mention of the native population upon whose willing, if not enthusiastic, co-operation the project depends. The experience of forced labour for public works is not unknown in East Africa, but it is disappointing that, even before the native response has been tested, the probable need to apply conscription is foretold. A favourable voluntary response from the Baganda, Basoga and other peoples—so very desirable in the interest of the success of the plan, if for no other reason—would largely depend on the moral as well as material incentives which were laid before them. Moreover, the communities of Uganda vary so much between themselves in their traditions and skills that the significance of these factors from the point of view of the plan must be investigated very early. The absence from the report of considerable reference to distinctions between one native community and another suggests the hope that a separate report to include such matters may soon be possible. Estimates of the population (3,956,700 in 1944) show an increase of rather less than two millions since 1911. Here, in the region of the upper Nile, there is no land-hunger comparable with that of Egypt, and it is possible to plan economic development free from pressing anxiety. It is confidently predicted that the population of Uganda will attain ten millions before the end of the century, although the influence of such serious checks on increase as have occurred during the last thirty years should not be under-estimated.

Dr. Worthington's proposals seem to be in harmony with the official view that peasant agriculture must remain the basis of Uganda's economy for a long time to come, even though, in the opinion of the Governor of Uganda, who contributes a foreword, the introduction of European-owned estates and concessions would offer greater prosperity to the Protectorate. The raising of the standard of life can be achieved only by a progressive increase in the productivity of the soil, and the author, offering a warning against a possible dissipation of effort and funds, proposes for the immediate future with which his plan is concerned concentration upon certain experimental projects, known as "pilot schemes", in selected areas. The first of these is to be in South Busoga, at one time known as the "garden of Uganda", along fifty miles of the shore of Lake Victoria between Jinja and Mjanji.

There is a difference in objective between the pilot schemes, as proposed for Uganda, and the well-known groundnut scheme which has been devised for the agricultural betterment of British territories farther to the south in East Africa. The main purpose of the latter scheme, which is intended only for sparsely populated districts, is maximum production of an export crop with the minimum of trouble and with the minimum of native labour, but with a comparatively high proportion of white employees. On the other hand, the pilot schemes of Uganda are intended for the advancement of the standard of life in a comparatively well-populated protectorate, while they both anticipate and encourage the highest density of population which is compatible with efficiency. It is expected that each pilot scheme will involve about £1 million over ten years, with European to African employees in the ratio of about 6 : 6,000.

In its various scientific services Uganda, in common with neighbouring British territories, requires generous expansion; and in meteorology, hydrology, etc., suitable recommendations are made, including the request for the preparation of an atlas of Uganda. For this last-mentioned enterprise the model might well be the "Atlas du Katanga", the first maps of which were published many years ago by the Belgian Government of the Congo.

Tsetse control is perhaps the most urgent of needs, and the widespread invasion of Uganda by fly demands the establishment of a tsetse control department which would plan attacks on the pest from strategic points. The policy of protection, improvement and development of natural resources, with its inevitable emphasis on agriculture, fully justifies the proposed expansion of the Agricultural Department and the foundation of a chair of agriculture at

Makerere College. The expansion of the Uganda Museum is another project of importance to both research and education, and will be concerned both with ethnology along lines already well established and with the evolving life of the native communities.

Every aspect of public service, such as transport and hydro-electric power, receives attention. The scarcity of coal and other fuels necessitates the utilization of the water resources, particularly Lake Victoria, Africa's greatest reservoir. A scheme involving control of the lake-level would provide an ample margin of power, over and above the demand foreseeable within the next ten years.

The maps which accompany the report are well selected, but their uniform scale is too small for the detail of the various distributions shown, and legibility is not always guaranteed.

WALTER FITZGERALD

THORPE'S DICTIONARY

Thorpe's Dictionary of Applied Chemistry

Fourth edition, revised and enlarged. Vol. 8: Meths-Oils, Essential. Pp. viii + 679. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1947.) 80*s*. net.

THERE can surely be few works of reference which provide so rich a harvest of knowledge as this latest volume, just issued, of Thorpe's "Dictionary of Applied Chemistry". Many of the writers are not only experts in their special fields of interest but are also active workers engaged in the promotion and extension of this knowledge. The impression gained by reading many of the articles written by distinguished authors is that no chemist, whether in the academic or industrial field, can venture far in his subject without having this volume for reference.

The subjects comprised under the titles from "Meths-Oils, Essential" include a mass of general topics of more than ordinary interest in present times. There are also others to which one would go for a fundamental and historical background of subjects of more common interest.

Prof. E. F. Burton of Toronto writes on the electron microscope, Dr. G. B. B. M. Sutherland on infra-red and Raman spectra, and Prof. R. A. Morton on visible and ultra-violet molecular spectra. These articles give a conspectus of present knowledge and of the methods of investigation in these fields. The editors are to be congratulated on having secured, shortly before his death, a valuable article from that veteran, Prof. V. M. Goldschmidt, on geochemistry of minerals. Minerals and X-ray analysis are ably dealt with by Dr. F. A. Bannister of the British Museum (Natural History), and Dr. L. J. Spencer contributes other articles on minerals. Dr. L. E. Sutton, of Oxford, has written on electric dipole moments. Prof. J. R. Partington has contributed the article on nitrogen and the utilization of atmospheric nitrogen, and Prof. J. H. Quastel has dealt with biological nitrogen fixation. Nucleic acids are ably discussed by the late Prof. J. M. Gulland and G. R. Barker, and there is included an article by Dr. C. J. G. Knight on growth factors for micro-organisms, a subject of current interest in view of the manufacture of biosynthetic products.

An authoritative article on octane number is contributed by Mr. F. L. Garton of the Shell Petroleum Co. and another by Dr. J. H. Burgoyne on methane as fuel. Micro-chemistry in most of its aspects is dealt with in great detail, including micro-chemical operations and drop reactions and organic micro-analysis. The major contribution to this volume is that by Dr. E. H. Rodd and his collaborators on naphthalene, which covers this field and provides an important monograph in itself and occupies 176 pages.

Generally the standard of the articles is high and the space allotted to each subject adequate, in some cases amply so for a chemical dictionary. Care has been exercised in the selection of contributors, and in many cases these are men of front rank. Where a large field must be covered in limited space, as in the article on high-vacuum distillation (molecular distillation) by Dr. K. C. D. Hickman of Rochester, N.Y., an exhaustive bibliography accompanies the article. A noteworthy contribution is one on molecular beams by Prof. O. R. Frisch of Cambridge.

The volume is well presented on good paper with sufficient margins and a sturdy binding.

NORMAN HAWORTH

QUALITATIVE QUANTA

The Strange Story of the Quantum

An Account for the General Reader of the Growth of the Ideas underlying our Present Atomic Knowledge. By Banesh Hoffmann. Pp. xi+239. (New York and London: Harper and Brothers, 1947.) 3 dollars.

IT is perhaps ungrateful to begin the review of this delightful book with a complaint, but it is surely unnecessary to state Planck's constant on p. 22 as a pure number. Apart from this, the reviewer must add that no book of popular science since 'Mr. Tompkins'' exploration of the atom has given him such keen pleasure in the reading.

The object of the book is to give for the benefit of the general reader as complete an account of the development of modern quantum theory as is possible without the use of mathematical symbolism. Dr. Hoffmann's general reader, however, must be gifted with an uncommon degree of intelligence and mental agility if he is to derive any clear idea of the developments after 1925 of the theory from a first reading of this book. The author's method of presentation reminds one of a man with a club hewing his way through a hostile mob. The historical development is followed quite accurately, and as each point arises, the probable consequent misconceptions are mustered, presented in their most formidably persuasive form, and then, in the next paragraph, down comes the club. They are knocked on the head and dropped in the gutter, and Dr. Hoffmann advances triumphantly, with the reader, a little breathless and apprehensive, tugged along in his wake. This is showmanship in the grand style, but there is no sacrifice of accuracy in the physics for its sake.

"The Strange Story of the Quantum" succeeds above all in showing that science is no static dry-as-dust body of knowledge. The author's quick-moving style recreates the excitement of the mid-1920's when quantum theory was beginning to assume its modern form. He makes it clear how successive ideas came into contradiction with experience and were replaced, and he emphasizes the precarious state of the present-day physics, with relativity and quantum theory uneasy bedfellows. The pages carry a foam of witty remarks (some of which are not too easy for the non-American to understand), and it is not the least commendable point of the book that Dr. Hoffmann, perhaps because he is a mathematician rather than a physicist, is not deterred by professional solemnity from making it clear beyond any doubt that 'physics is fun', a truth well known but too rarely expressed.

G. WYLLIE

BRITISH DIVING BIRDS

Haunts of British Divers

By Niall Rankin. Pp. 96 + 83 plates. (London: Wm. Collins, Sons and Co., Ltd., 1947.) 12s. 6d. net.

THE series of beautiful books which are being issued under the title of "The New Naturalist" receives a most welcome addition in the present volume, devoted to the account of three birds, the great crested grebe, the black-throated diver, and the red-throated diver.

Colonel Rankin, who owns the famous sanctuary on the Isles of Treshnish in the Hebrides, is not only a keen naturalist but also a first-class photographer. The result is a graphic picture of one of England's most attractive water-fowl, and two of Scotland's lesser known birds in the Highlands and Hebrides, accompanied by striking views of the romantic country in which they occur.

The account of the great crested grebe occupies the first half of the book, and is based on observations on a favourite home of these birds, a large tree-fringed lake in Kent, where eight or nine pairs regularly breed and many spend the whole year without migrating. The breeding and nesting habits are described in detail. Special mention should be made of the striking series of photographs showing the feeding of the chicks, and in particular the peculiar habit of each parent of plucking feathers from its own breast and feeding them to its offspring.

The black-throated diver does not breed south of north Perthshire and Argyll, but becomes commoner to the north, although it is not known to nest in the Orkneys and Shetlands. A remote loch in Sutherland provided the material for this study, based on a single pair of these handsome birds. The red-throated diver, a circumpolar species, has a more northerly distribution, and is comparatively common in the Orkneys and Shetlands. The author selected the island of Unst, to the extreme north of the Shetlands, for the study of this species, and also took the opportunity of making observations and illustrations of the sea-birds so abundant in that area. The curious breeding behaviour of the red-throated diver, including the position created when the duty-bird on a nest was approached by three other divers, including the 'other half' belonging to this nest, presents an interesting problem in animal psychology.

The author, in his introduction, modestly states that he offers nothing new to ornithology. Whatever the truth of this statement, he offers the reader the personal observations of a keen observer accompanied by excellent photographs, which constitute a valuable addition to our knowledge of bird behaviour, and will be welcomed by all naturalists.

In addition to the eighty-four photographs by the author, special mention should be made of the coloured frontispiece and eleven pen-and-ink drawings by Margaret Myddelton.

E. HINDLE

A NATURALIST'S NOTES

Highland Naturalist Again

A Gamekeeper's Observations and Discoveries. By Dugald Macintyre. Pp. 220 + 8 plates. (London: Seeley, Service and Co., Ltd., n.d.) 15s. net.

DUGALD MACINTYRE, during his long life spent in observing living creatures, has amassed a store of knowledge of the wild life of the Scottish Highlands equalled by few. In this, his latest book, he discourses on seal and hare, ptarmigan and capercaillie, gull and jackdaw, and a host of other creatures. He has a good word to say for the rook, for in spite of its misdeeds in eating grain and potatoes it is the farmer's friend in spring. Let me quote Mr. Macintyre (p. 133): "Billions of leather-jackets, which are the farmer's worst insect enemies, were taken from the fields of young oats and barley and wheat by the foraging rooks. Crops grown near the rookery grew well in bad years for 'grub', when crops too distant for the rooks to reach were destroyed almost to the last blade. There was one big farm many miles from the nearest rookery and rooks were never seen on that farm, so the crops suffered much from grub."

He describes an osprey fishing on Loch Awe in winter. That, surely, must be a very rare occurrence, for the osprey, when it nested in the Highlands, was a summer visitor only, and now that it nests with us no longer it is seen on spring and autumn migration, to and from its haunts in Central Europe.

Were Mr. Macintyre a less competent observer his statement (p. 166) that: ". . . while the loch [Loch Awe] remained wholly free from frost, but when its shallows were frozen over, the osprey was driven inland, and necessity compelled him to take other food than fish. The gamekeeper found him one day making a meal of a grouse, far inland from the loch: on another snowy day a wild-fowler of Loch Etive saw him pursue and take a wounded widgeon" would be received with at the least grave doubts, for at the season when the Loch Awe shallows freeze the osprey is normally basking in the warmth of the African sun.

On p. 162 Mr. Macintyre mentions that the Scottish capercaillie became extinct about the middle of the eighteenth century, and that the present stock is descended from birds introduced from Sweden. He makes the interesting suggestion that the birds are susceptible to disease, and that for this reason the stocks in certain districts are again decreasing fast.

The felling of great areas of Scots pine during the war years, a felling which still continues, has been injurious to the capercaillie, and the bird is also killed on all land of the Forestry Commission, on account of its habit of destroying the tender leading shoots of conifers. It would be regrettable if the caper were to die out a second time, for it is a noble bird, and adds charm to the dark miles of the old Caledonian Forest, where its cousin, the black grouse, has also become much scarcer during the last score of years.

The publishers of "Highland Naturalist Again" are to be congratulated on the printing of the book, and its excellent paper, in these days of restrictions and difficulties: there are several excellent illustrations, supplied by leading Nature photographers.

SETON GORDON

JAMES HUTTON (1726-97) AND SIR CHARLES LYELL (1797-1875)

By V. A. EYLES

H.M. Geological Survey of Great Britain

THIS year, the hundred and fiftieth anniversary of the death of James Hutton, who has justly been styled the 'father of modern geology', has been made the occasion for a number of commemorative meetings in Scotland, the land of his birth. Addresses have been delivered to the Geological Societies of Edinburgh and Glasgow; and, on November 3, at a special meeting of the Royal Society of Edinburgh, Sir Edward Bailey read a paper on the "Life and Work of Hutton" [see p. 727]. On the same day the Lord Provost of Edinburgh unveiled a memorial tablet in Greyfriars Churchyard. This plaque was appropriately cut from granite, the igneous origin of which was first demonstrated by Hutton; and it was placed close to his hitherto unmarked grave.

It is, of course, especially fitting that such a celebration should have been arranged by the Royal Society of Edinburgh, because the first account of Hutton's famous theory of the earth was read to the members of that Society in 1785, and published in the first volume of the Society's *Transactions* in 1788[1].

Hutton was deeply interested in many branches of knowledge, particularly chemistry and agriculture; but his claim to fame rests on his contributions to the science of geology. These were finally embodied in full in his two-volume "Theory of the Earth with Proofs and Illustrations", published in Edinburgh in 1795. Some further parts of the "Theory", which remained in manuscript form for many years, in the possession of the Geological Society of London, were published by that Society in 1899, as Volume 3 of the "Theory".

Unlike many earlier theories of the earth, such as that of Burnet, and others of the 'physico-theological' school, as it has been termed, a number of which were published in the latter part of the seventeenth and during the eighteenth century, Hutton's theory in its final form was firmly based on deductions made from first-hand observations of the rocks themselves. These he had carried out for many years, often accompanied by friends with whom he discussed his ideas. He also entered into frequent debates, in Edinburgh, with other prominent Scottish men of science, notably Black, the chemist. He read, too, much of the contemporary literature that was relevant to his researches, and this, no doubt, influenced his ideas. Finally, in reaching his conclusions, he was not deterred, as were so many previous writers (and indeed later authors), by the knowledge that his ideas ran counter to the doctrines of the established church.

In spite of the manifest truths, as they now seem to us, that were contained in Hutton's great work, his conclusions met with much opposition, and it was many years before they obtained full recognition. Various causes contributed to this delay. Chief among them was the influence of Werner, whose doctrines, for the most part completely at variance with those of Hutton, were widely accepted at that time and for some years afterwards, not only on the Continent, but in Great Britain also. A contributory cause was that Hutton's style was so obscure and difficult to follow that it may well have prevented some readers from fully apprehending his theories; and, in any event, it seems that his book became so scarce within a few years of his death that it may have been inaccessible to some geologists. Fortunately, a re-statement of the Huttonian doctrines, written in a clear and elegant style, appeared in 1802. This was the "Illustrations of the Huttonian Theory of the Earth", written by Hutton's intimate friend, John Playfair. It was widely read and almost certainly more effective than Hutton's own book in spreading the latter's ideas.

Shortly after Hutton's death, Playfair wrote a biographical account of his friend. Little that is new has since been published about Hutton the man[2]; but during the past hundred and fifty years a number of competent authors have analysed his work[3]. The grain has been sifted from the chaff, and the debt that their science owes to the patient labours of Hutton has been made clear to modern geologists. His contributions to geological thought are now too well-known to need particularizing here.

It is, however, worth recalling that the year of Hutton's death, 1797, is also memorable as the year in which another almost equally distinguished Scottish geologist, Sir Charles Lyell, Bart., was born; particularly because Lyell, probably more than any other, was instrumental in securing the general acceptance, in Great Britain, of the teachings of Hutton. This he did through the medium of his classic, "Principles of Geology", which, first issued in 1830–33, in three volumes, went through twelve editions in the succeeding forty-five years, and was also published in the United States. It was said of Lyell by Sir Andrew Ramsay, "We collect the data and Lyell teaches us to comprehend the meaning of them". Though chiefly distinguished as a critic and writer on the researches of his forerunners and contemporaries, Lyell was no mere armchair geologist and compiler of text-books. He travelled widely both in Britain and abroad, and during his travels widened his ideas, not only by geological field-work, but also by contacts with leading foreign geologists.

When, ultimately, Lyell's matured views were published in the "Principles", he acknowledged his debt to Hutton by inserting at the beginning of Volumes 1 and 2 of the first edition, quotations from Playfair's "Illustrations". In addition, in the historical introduction that occupies the first five chapters of his work, he discusses Hutton's "Theory" against the background of geological ideas that were current when it was published. In spite of this, he was criticized by a contemporary, W. H. Fitton, for not giving due weight in this summary of the history of geology to the importance of Hutton. Writing in the *Edinburgh Review*, in 1839[4], Fitton stated, in reference to Lyell's "Principles", "We think that Mr. Lyell has not, either in his preliminary history or in the body of his works, done quite sufficient justice to the claims of Dr. Hutton—whom we conceive to be effectively the author of the Theory of the Earth now most universally received; . . . This defective appreciation of Hutton we have no doubt may be ascribed, in a great measure, to the direction given by accidental causes to Mr. Lyell's own pursuits; but it is the more unfortunate, as the public and the general reader will naturally make a work so popular as the 'Principles of Geology' their text-book and authority; while many eminent men, engaged in the cultivation of other departments of physical science will be content to take their impression from the clear and fluent pages of that publication; with some indifference, perhaps, as to the relative merit of those by whom geology has been advanced to its present state."

Lyell received Fitton's review while staying at his father's house at Kinnordy, Angus, and at once replied to the reviewer in a long and interesting letter[5], in which he defends himself from the charge of neglecting to give Hutton his due. The following paragraphs are of particular interest. In referring to Hutton's "Theory", Lyell states: ". . . I found it difficult to read and remember Hutton, and though I tried, I doubt whether I ever fairly read more than half his writings, and skimmed the rest"; and he also records that "The mottos of my first two volumes were especially selected from Playfair's Huttonian Theory, because although I was brought round slowly, against some of my early prejudices, to adopt Playfair's doctrines to the full extent, I was desirous to acknowledge his and Hutton's priority, and I have a letter of Basil Hall's [son of Sir James Hall, intimate friend and supporter of Hutton] in which . . . he comments on the manner in which my very title-page did homage to the Huttonians, and complimented me for thus disavowing all pretensions to be the originator of the theory of the adequacy of modern causes".

In the last part of the letter Lyell writes: "It was my business, in tracing the progress of our science to its present state, to estimate the importance of each writer, and adjust the quantity of space due to him in my historical sketch, not simply according to his originality and genius, but partly at least in proportion to his influence; and I still think that Werner's eloquence, popularity, enthusiasm, and position at Freyberg, placed him in this point of view as much above Hutton as I have represented him to fall below him in reference to the truth of his theories. Yet as an admirer of Hutton all I could have wished is, that your panegyric on Hutton had appeared as aiding and seconding my efforts, since I trust that no book has made the claims of Hutton better known on the Continent of late years than mine".

Lyell is, of course, correct in stating that the influence of Hutton on geological thought during the latter's life-time, and for some years after, was small compared with that of Werner, both in Britain and abroad. By the time the first volume of the "Principles" was published, the influence of the Neptunists, as Werner's followers were called, was definitely on the wane in Britain; but there were still a few 'die-hards' among the more prominent geologists who, though perhaps no longer subscribers to the doctrines of Werner, were yet reluctant to swallow Hutton's teachings in their entirety. Such a one was Adam Sedgwick, professor of geology at Cambridge and president of the Geological Society of London, who attacked Lyell in a presidential address to the latter Society, in 1831, as being, in the "Principles", "the champion of a great leading doctrine of the Huttonian hypothesis"[6]. Lyell's claim, too, that his book influenced continental geologists appears to be well founded. The "Principles" was translated into French and German, and Zittel, in his "History of Geology"[7], states, "In Germany . . . Lyell's works attained immediate celebrity and were made widely known by several translations". In this connexion, however, it should not be overlooked that a French translation of Playfair's "Illustrations" had been published in Paris in 1815[8].

Whether or not Lyell fully appreciated, at the time he wrote the "Principles", the fundamental importance of Hutton's theories, upon which a very large part of the superstructure of modern geology now rests, the judgment of posterity leaves us in no doubt regarding the eminence, not only of Hutton, but also of Lyell himself. Our debt to these two masters has been admirably expressed by Sir Archibald Geikie in his "Founders of Geology": of Hutton he wrote: "The dominant idea in his philosophy is that the present is the key to the past. We have grown so familiar with this idea, it enters so intimately into all our conceptions in regard to geological questions, that we do not readily realize the genius of the man who first grasped it with unerring instinct, and made it the chief cornerstone of modern geology"[9]; and of Lyell he asserted: "But of the English writers of general treatises of geology, the first place must undoubtedly be assigned to Charles Lyell who exercised a profound influence on the geology of his time in all English-speaking countries. Adopting the principles of the Huttonian theory, he developed them until the original enunciator of them was nearly lost sight of. With unwearied industry he marshalled in admirable order all the observations that he could collect in support of the doctrine that the present is the key to the past"[10] . . .

In conclusion, one cannot do better than quote the opinions of the late Sir John Flett; of Hutton's "Theory" he says it was "at once supremely original and perfectly conclusive"[11]; and, referring to Lyell, he states, "By his easy, liquid style, his transparent sincerity, his profound knowledge of the literature and his judicial sense of the value of evidence, Lyell takes the highest place among the expounders of geological science. His work is the greatest and most famous classic in the literature of the subject. To him also we owe the conversion of Charles Darwin, while still a young man, to the orthodox theories of geology. Before Lyell's time scientific geology was already current and widely accepted, though there were still unconverted adherents of the older schools. But Lyell made the subject intelligible to all, so that he who runs may read. Darwin in his journals has recorded the profound impression made on his mind by the first reading of the 'Principles of Geology'. The science had emerged from the mists and obscurity of the cataclysmic school and the Wernerians, and was founded on the sure basis of observation interpreted in the light of the processes operating in the world around us at the present day."[12]

MECHANICAL PROPERTIES OF METALS

CONFERENCE AT BRISTOL

A SUMMER school and conference on the mechanical properties of metals was held at the University of Bristol during July 2–9. At the summer, school (July 2–5) a course of lectures was given by Prof. N. F. Mott, Mr. F. R. N. Nabarro and some of their colleagues on the theory of the subject, especially on dislocations, plastic flow and precipitation. During the conference, papers mainly on experimental topics were given by physicists from various countries, including Meijering (oxidation hardening), Weil (ordered state in alloys), Druyvesteyn (mechanical properties at low temperatures), Andrade, Orowan, Chalmers, Cottrell (creep), Shockley (slip planes in silver halides), Lacombe (crystal boundaries), W. G. Burgers (recovery and recrystallization), Crussard (diffusion studied by thermo-electric methods), Guinier (precipitation), Snoek (elastic after-effects in iron), Guillet (internal friction), McKee and Leadbeater (powders).

Some of this work has already appeared in scientific journals, and many of the papers will be published in a special number of the *Proceedings of the Physical Society*; in this article it seems, therefore, more useful to pick out some salient points from the conference rather than to attempt a report on each paper.

Creep and Plastic Flow

From the experimental side a clear distinction was made by nearly all speakers between 'transient' and 'viscous' creep. Transient creep occurs when a metal, either a single crystal or a polycrystalline specimen, is stressed beyond the elastic limit; after an initial instantaneous extension the rate of strain $\dot{s}$ drops rapidly with increasing time t. Andrade[1] in his pioneering work on the subject gave for polycrystalline metals the formula

$$\dot{s} = \beta t^{1/3},$$

which can be derived from

$$\dot{s} = \text{const}/s^2.$$

In more recent work[2] on cadmium, he suggests for the flow of single crystals

$$\dot{s} = Ae^{c/s}.$$

Orowan more recently[3] has put forward the formula

$$\dot{s} = \frac{\text{const}}{s^2} \exp(-\alpha s^2/kT),$$

where the constants depend on the stress and temperature. It is characteristic of transient creep that: (*a*) it is a phenomenon taking place in single crystals or within the grains of polycrystalline materials; (*b*) it always takes place, even at quite low temperatures, following an instantaneous deformation of the material by any stress exceeding the elastic limit.

Viscous creep is the term given to the ultimate steady rate of creep which is obtained in certain cases. The term 'viscous' is slightly misleading, since, of course, the creep-rate is proportional to a high power of the stress. According to Andrade, in the early stages of creep there is rotation of the crystallites, accompanied by glide on crystal planes, but the final stages of true viscous creep in polycrystalline materials take place in a narrow zone surrounding the crystal boundaries, there being no deformation of the crystals as a whole at this stage.

In trying to understand creep, one has first of all fairly clear evidence that slip of one crystal boundary over another can occur and is a truly viscous process, the rate being proportional to the stress. A recent paper[4] from Zener's school in Chicago has used measurements of internal damping and other anelastic effects in pure polycrystalline aluminium to obtain a figure for the rate of slip at the grain boundary in this metal. The result is

$$\text{Rate of slip} = \text{stress} \times 5 \times 10^8 e^{-17,250/T} \text{ cm./sec.}$$

Of course, unless the grain boundary is flat (or of constant radius of curvature), any slip along the boundary will set up elastic strains near the surface of the grains; these strains are probably the cause of intercrystalline failure in creep tests in lead and other metals. Viscous creep possibly has its origin also in this grain boundary slip, which for large values of the applied stress will proceed until deformation takes place in the protuberances of the grain surface which lock the grains together. (This seems to be in accord with the observations of W. A. Wood and H. J. Tapsell[5], who find that a specimen of aluminium extended 0·9 per cent at 300° C. in a creep test shows little deformation of the reflexion spots from the grains; while, after a rapid deformation followed by heat treatment at 300° C. for an equal time, the deformation is much greater. They deduce that in the former case slip is mainly along grain boundaries; in the latter, deformation of the whole crystal occurs.) Since the stresses involved in grain-boundary slip can reach values much greater than the applied stress, one may expect deformation of the boundary region to occur until recovery or recrystallization sets in. The steady creep-rate, then, will be reached when hardening and recovery in the boundary regions just balance each other, and any quantitative theory must await a theory of these processes.

For transient creep, the elements of a theory are beginning to appear, based on the concept of dislocations. In any theory of this type, one has first to ask: Is the resistance to deformation shown by actual materials due to the difficulty of forming dislocations, or to the difficulty in moving them? The obvious fact that hardness increases with all kinds of internal strains and impurities suggests that the latter is the case. The source of dislocations remains something of a mystery; grain boundaries and mosaic boundaries (which can probably be represented as rows of dislocations) are possible sources, and, in slip bands, dislocations which have been set into rapid motion almost certainly generate others. However, for considerations of transient creep, it is probably adequate to consider that enough dislocations exist already.

One then ascribes the resistance to yield of any material to the internal stresses σ_i which exist in a material due to grain boundaries, precipitates or 'stuck dislocations'. These will prevent the motion of dislocations unless the applied stress σ exceeds σ_i. In this, one follows G. I. Taylor's theory of strain hardening[6]; but, as emphasized by the present writer, the deformation of single crystals, which harden rapidly, is theoretically a much more complicated problem than the deformation of hard materials (for example, precipitation-hardened alloys); in a hard material, investigations of creep or deformation will give information about the motion of dislocations under internal and external stresses which remain constant during the experiment.

According to the theory of Becker and Orowan, the energy of activation required to move a dislocation from one position of equilibrium to another, if the applied stress is σ, is

$$V(\sigma-\sigma_i)^2/2G.$$

Here G is the shear modulus, and V a volume of order $(200\,\text{A.})^3$. Arguments were given by the present writer for replacing this (for precipitation-hardened materials) by

$$U(\sigma_i) = 0{\cdot}1\,\sigma_i a\lambda^2\left(1-\frac{\sigma}{\sigma_i}\right)^{3/2}.$$

Here a is the interatomic distance, and λ the distance between centres of stress. The chance $\alpha(\sigma_i)$ that a dislocation moves forwards is then, per unit time,

$$\alpha(\sigma_i) = \nu\exp\{-U(\sigma_i)/kT\}.$$

As Orowan[3] in particular emphasized, in transient creep, when the instantaneous extension is at an end, dislocations will be present in the material in positions for which σ_i has all values from σ upwards. Thus creep is, initially, a process of which the rate is determined by activation energies $U(\sigma_i)$ with all values from zero upwards. As the dislocations in particularly favourable positions, that is, those with small $U(\sigma_i)$, are used up, the creep-rate slows down. If $N(\sigma_i)\,d\sigma_i$ ($\sigma_i \geqslant \sigma$) is the number of dislocations, at the end of the instantaneous extension, in positions for which σ_i lies in the range $d\sigma_i$, then after time t the number is $N(\sigma_i)\exp\{-\alpha(\sigma_i)t\}d\sigma_i$. The creep-rate is thus proportional to

$$\int_\sigma^\infty N(\sigma_i)\,\alpha\exp(-\alpha t)d\sigma_i.$$

On the assumption that $N(\sigma_i)$ is constant, this integral has been worked out by the present writer. One obtains an extension-time curve of the type

$$S = \text{const}\,\{\log(\nu t)\}^{2/3},$$

where $\nu \sim 10^9$ sec.$^{-1}$. Such a curve seems to represent transient creep at low temperatures (for example, for lead, Andrade, *loc. cit.*), but certainly does not cover the whole range of phenomena described as transient creep.

An interesting extension of the dislocation theory was given by Cottrell. Cottrell showed that impurities in solid solution would be present in abnormally low or high concentrations in the neighbourhood of a dislocation; he spoke of a "Debye–Hückel atmosphere" of dissolved atoms around a dislocation. This atmosphere, if it is given time to form, will anchor a dislocation in position, introducing a definite local value of σ_i and hence accounting for the existence of a sharp yield point. The explanation was particularly apposite in the case of iron, where the yield point may be taken to depend on the segregation of the easily mobile carbon atoms around the dislocations. Snoek demonstrated to the Conference that the purest iron (less than 0·0001 per cent of carbon by weight) does not have a yield point. It may also be of importance in explaining the considerable observed dependence of yield point on temperature for most metals, on which Druyvesteyn reported to the Conference. It is inherent in the theory of transient creep sketched above that the activation energy $U(\sigma_i)$ is very large in comparison with kT unless σ is within a few per cent of σ_i; therefore, the dependence of yield stress on temperature cannot exceed a few per cent unless the internal stress σ_i is itself temperature-dependent. Cottrell's assumption of an atmosphere of dissolved atoms in equilibrium around the dislocation will obviously lead to a decreasing resistance to yield as the temperature rises and the atmosphere is driven away. The theory also gives an elegant explanation of the phenomenon of micro-creep observed by Chalmers[7] in tin, where the creep-rate for small stresses is proportional to stress; in this process dislocations move, carrying their atmosphere of impurity atoms with them.

Internal Friction

Snoek[8] reported on his work on the elastic after-effect in iron; he showed that damping of vibrations in iron is partly due to the dissolved carbon atoms which set up local stresses, and which, in jumping from one equilibrium position to another, absorb energy from the vibrations. Other work on internal friction, this time on gold-copper alloys, was reported on by Guillet, who pointed out the very low damping of the alloy Cu-Au after quenching; in this quenched alloy, presumably very small tetragonal domains are found.

One can now distinguish the following mechanisms which account for internal friction: (*a*) thermal currents between crystals of a polycrystalline material, or between strained regions of one crystal[9]; (*b*) slip along crystal boundaries, producing elastic strains in the adjoining material[4]; (*c*) presence of mobile dissolved atoms producing a tetragonal strain (for example, carbon in iron, as described above); (*d*) presence of mobile dislocations; internal friction of this kind is much reduced by annealing (recovery), and increased by quite small amounts of cold work[10].

The cause of absorption of energy from vibrations of small amplitude is not the motion of a dislocation from one position of equilibrium to another, but its vibrations about one position of equilibrium. The amplitude of vibration (and hence the damping) should for low frequencies be proportional to $\lambda^2(\sigma/\sigma_i)^2$, where λ is the distance between the centres of strain. Thus increasing hardness (increasing σ_i) gives low damping, as does also small values of λ. The small distance between the stressed tetragonal domains in the quenched Cu-Au alloy is likely to be the cause of the abnormally low damping.

W. G. Burgers[11] discussed recovery and recrystallization, and emphasized the difference between them. Recovery seems to be connected with the motion of dislocations, which move under each other's attraction or repulsion. In recovery, individual crystals retain their identity, and lose only part of their work hardening. In recrystallization, on the other hand, new crystals, having fully the properties of the annealed material, are formed and eat up the cold-worked material by a process at present little understood, but not so obviously connected with the motion of dislocations.

Diffusion and Precipitation

Meijering discussed the oxidation of silver containing aluminium in solid solution. Oxygen dissolves readily in silver, but the binding energy is small. The binding energy of aluminium and oxygen is large, and oxygen atoms diffusing in from the surface are trapped when they encounter aluminium atoms. A sharp boundary is formed between the interior of the specimen, which contains aluminium atoms in solid solution, and the exterior, which contains single molecules of aluminium oxide. These molecules are too large to diffuse through the lattice, and their binding energies are so high that they are unable to dissociate and diffuse as single atoms. Oxidation hardens the alloy, and the normal effects of over-ageing, leading to softening and the formation of microscopic particles of precipitate, are suppressed.

An X-ray analysis of more usual types of precipitation was reported by Guinier. His results, parts of which have already been published[12], are obtained by the use of a single-crystal specimen and monochromatic radiation. In aluminium-copper alloys, where the solute atoms differ in size from those of the solute, the initial nuclei of precipitation are plates one or two atoms thick and about 25 A. in diameter. From absolute intensity measurements he finds that about a fifth of all the copper atoms form such plates, the remainder staying in solid solution. The initial nuclei are about 90 A. apart. In the aluminium-silver alloys, where all atoms are of nearly the same size, the initial nuclei are roughly spherical, and may be considered as sinusoidal fluctuations in the concentration of silver atoms with a wave-length of about 70 A.

THEORY AND PRACTICE OF DYEING

THE symposium held by the Society of Dyers and Colourists at Blackpool during September 25–27, to discuss recent advances in textile coloration, may prove to be of great importance, not only in the annals of the Society itself, but also in the modern history of the subject. The interests of the Society have always ranged very widely, including, at one end of the scale, the industrial production of tinctorial materials and processed fabrics, and, at the other, fundamental studies of textile fibre properties and the chemical and physical processes underlying the operations of dyeing, printing, finishing, etc. Increasingly in recent times, due principally to the growth in the physical sciences, and the narrowing specialization thereby encouraged, it has become difficult for workers situated at these antipodes to know about and to appreciate the significance of each other's work. This symposium marked a *rapprochement* perhaps more significant and more far-reaching than could properly be conveyed by the most careful and accurate summary of the material in the papers read and in the discussions which ensued.

The programme was almost as variegated as the interests of the members. A group of papers contributed by Dr. T. Vickerstaff and his colleagues of Imperial Chemical Industries, Ltd., by Mr. J. Crank of Courtaulds, Ltd., and by Dr. S. M. Neale and Mr. J. M. Preston of the Manchester College of Technology, attempted to define quantitatively the intimate mechanisms of dyeing processes in terms of the energy changes occurring during the processes, or by reference to the active chemical groupings and fine structure of the fibres. What may be called without disparagement the empirical technical side included an informative and well-arranged review of American and German dyeing methods by Dr. R. G. Fargher of the Shirley Institute, a discussion of automatic temperature control in dyeing machines, analytical methods for the identification and assaying of dyes, technical advances in the dyeing of acetate rayons, etc. The latter, the technical, group of papers had, of course, the wider appeal and the more general intelligibility, and they were discussed at length from all parts of the meeting. The first group, however, might fairly be said to have shown itself to be of the greater significance for future development and to have presented the most interesting, and, in the discussions that followed, the most amusing impression to the general observer.

The papers in this group were couched largely in the language and symbolism of physical chemistry, and, in spite of very ingenious interpretative efforts on the part of the protagonists, especially Dr. Neale, their direct and ultimately weighty influence on industrial procedure could not be fully appreciated by many of those whose daily concern is the bulk-production of finished textiles for a competitive market. This situation did not, as it might have done, result in a wider cleavage, but led rather to attempts to define the function of the technologist as the agent for bringing about a liaison between the two sides, and a call for the increased intake of young trained scientific workers into the textile industries. This point of view was put very forcefully and cogently in the discussions by Mr. R. J. Hannay, himself a chemist and calico printer of wide experience and consistently progressive attitude. What may be regarded in some degree as an admonition to both sides came from Dr. E. B. Abbot of I.C.I., who reviewed many of the recent advances in our knowledge of dyeing mechanisms, and attempted to show the extent to which this knowledge has been, or could be, made applicable in the conduct of full-scale processing operations. One most important statement is best given in Dr. Abbot's own words. "A criticism frequently levelled at research workers by technologists is that they are too far removed from realities. In the case of the direct dyes on cellulose, however, we feel that much of the research work has, on the contrary, been too closely related to narrow practical aims, and has consequently lacked that breadth of speculative perception by which primary truths are revealed. We believe the type of research carried out by Neale and his co-workers on direct dyes and cellulose to be more correctly motivated, but an extension of this work, particularly towards a wider examination of different dyes, is required." For this report to do justice, it must be said that, in the discussion, a very strong attempt was made to justify what may be called the interim type of investigation, in which technical behaviour of a range of dyes is defined quantitatively and working rules are enunciated without immediate reference to ultimate causes. In long-established industrial processes such as dyeing, where superficially simple operations exploit a very complicated interplay of variables, these interim investigations often represent the only practicable first assault on the technical problems that need to be solved. There is a danger in this type of investigation that the volume of data which may accumulate from the use of comparatively simple experimental methods may obscure the limits of its value and may lead to premature complacency.

An attempt may now be made to deal in greater detail with the contents of the more fundamental papers. Following the general line of progress in dyeing theory, it may be said that these papers again emphasized the greater ease and certainty of the theoretical treatment of the dyeing process for basic fibres as compared with cellulose. The papers, and the discussions that followed, showed clearly that the authors had reasonably adequate physico-chemical machinery at their disposal for testing and developing their theories, once they had decided on the theoretical mechanism to be tested; but it was soon obvious that the initial picture of the same or similar mechanisms differed markedly from author to author. This situation was to be expected in view of the great complexity of the total phenomenon under discussion, and it applied with particular force, as hinted above, to studies with the cellulose fibres. This situation lent support to the repeated contention by Dr. Neale that experimental attack must be pressed from as many different experimental angles as might be imaginatively possible. His own contribution consisted in a treatment of electrical field characteristics, due to ionic charges on the dyestuff particles and on the fibre surrounded by the aqueous dye solution, which control the approach of the dye particle to the fibre and modify the rate and magnitude of absorption which is ultimately effected by short-range forces. The experimental data were provided largely by the study of surface potentials at the fibre solution interface, and emphasized particularly the technically important influence of the presence of other small mobile ions such as sodium, chloride, etc.

The general picture of substantive dyeing processes with dyestuffs that are ionized in solution now appears to be fairly clear. The total process can be divided into three main steps: (*a*) a diffusion mechanism by which dissolved dye particles enter and leave an indifferent, porous, solid fibre, the equilibrium distribution of dye being imposed by purely mechanical conditions such as size, shape and velocity of the particles, and size and irregularity of the pores; (*b*) modifying this, an affinity factor, in which short-range chemical forces between dye- and fibre-substance encourage the retention of the dye; and (*c*) the creation of electrical double-layer effects due principally to the natural surface charge of the fibre and the immobilization thereon of dyestuff and other ions. The consideration of the last factor has been developed effectively by Neale and other workers to explain and evaluate the important technical effects of accompanying electrolytes in the dye-bath, since it has been shown, for example, that the Donnan membrane equilibrium principle can be used to account for ionic concentration differences within and without the fibre. Mr. J. Crank, of Courtaulds, drawing largely on the experimental data of Neale, further developed the study of the last factor. The original negative surface charge of the cellulose, augmented by the charges of adsorbed dye anions, is imagined to present a 'potential barrier' to the entry of further dye ions, a barrier which is penetrable only by ions which have a kinetic (activation) energy great enough to enable them to overcome the electrostatic repulsion. The free diffusion process is therefore modified by the fact that only a fraction, defined largely by the temperature, of the total external dye is available to penetrate a repulsive field the stopping power of which will be defined largely by the concentration of free and adsorbed dye and other ions. A method of calculating the magnitude of 'true' diffusion of the dye in cellulose (see *a* above) uninfluenced by chemical and electrostatic forces was worked out. Although the development of this method was necessarily incomplete, there is a promise that it may be possible to separate mechanical factors such as fibre orientation and dye particle-size from chemical factors in considering the dyeing of a specific dye on a specific fibre.

The chemical affinity factor was considered in detail by Dr. R. H. Peters of I.C.I. This work was based on the assumption by a number of previous workers that the attachment of dye to fibre is effected when, with favourable molecular dimensions in dye and fibre, hydrogen bonding can take place between specified active groups in the dye and hydroxyl groups in the cellulose. Following the adaptation by Vickerstaff and Peters of the Gilbert–Rideal equation, the standard free-energy change of the adsorption process was defined as the affinity of the dye. This value was calculated from adsorption isotherm data for the dyeing of a number of different forms of fibrous cellulose with a number of direct cotton dyes, with varying conditions of temperature and accompanying salt concentration. It was shown that the affinity so calculated is practically independent of the internal structure of the fibre for any one dye. The values of affinity as between one dye and another, dyes which, incidentally, deviate from each other very markedly in their exhaustion characteristics, are not of a very different order. The important deduction was therefore possible that the mode of attachment of dye to fibre is similar for all the dyes examined on all the fibres, the great individual differences observed in the dyeing behaviour of direct dyes being attributable to differences in the fine structure of the fibre and the state of aggregation of the dye particles.

A very similar picture was presented by Dr. Vickerstaff and Mr. D. R. Lemin as the result of an analogous treatment of the absorption of monobasic acid dyes by wool. The transfer of dye ions between solution and fibre was accomplished experimentally in different ways and calculations were made of the affinity. This was defined as the difference between the thermodynamic potential of the dye anion at unit activity in the solution and that of the same ion at unit activity in the fibre. The affinity of a particular dye calculated from the results of three different methods of determination, namely, direct adsorption, displacement of the dye from the dyed state by other anions, and competition of the dye with another for the fibre, led to reasonably consistent values. Here again, the affinity values were of a similar order of magnitude for all the dyes examined, so that a means seems to have been found for expressing quantitatively the strength of chemical attachment between dye and fibre, independent of many of the accidental properties of fibre and dye solution.

It is not the intention of this report, in thus singling out these two or three papers for special consideration, to diminish the value of the many other excellent ones that were discussed at the meeting. This group, however, with one other of a different kind, that of Dr. H. J. Selling of Delft, does appear to be of the greatest significance for the future, and the forward-looking spirit of the gathering was consistently maintained. Dr. Selling has made a heroic attack on a very difficult problem that has always attracted the interest of scientific workers in the dyeing industry. This is the specification of shades and the control of the dyeing process by means of the colorimeter, a process which, up to the present, has required almost complete reliance upon direct visual judgment. It was shown that patterns dyed with comparatively simple mixtures of dyes can be analysed colorimetrically with sufficient accuracy to allow matching dyeings to be produced solely on the data thereby furnished. Technically, this is a very considerable achievement, and although the method is not yet ready for general introduction into the dye-house, the beginning thus made is extremely promising. If instrumental patterning becomes possible, the next step may be automatic control of the course of the dyeing operation, and the dyer's Utopia will be in sight.

Apart from the very pleasant social atmosphere which marked the whole of the symposium, encouraged by the excellence of its management and the character of the discussions, one further item must be mentioned as contributing very markedly to the general success. This was the readiness of some of the larger firms concerned with the textile industry to allow their research staffs to make serious and extensive contributions from the results of work carried out in their laboratories. This attitude, so important for general progress, has not always been so much in evidence, nor is it yet universal. The chief guest at the Society's dinner was Mr. A. H. Wilson, recently University lecturer in mathematics at Cambridge, who, after a distinguished career in the field of pure science, now holds an important administrative position in the industry as director of research and development of Messrs. Courtaulds, Ltd.; his considered compliments on the scientific activities of the Society of Dyers and Colourists will be a source of great encouragement. H. A. TURNER

HOW FAR CAN BRITAIN FEED HERSELF?

THE Nutrition Society, at a whole-day conference held on October 25 at the London School of Hygiene, discussed "British Needs and Resources of Calories, Protein and Calcium". The Right Hon. Walter Elliott was in the chair.

The conference was planned some months ago, before the food situation became so threatening. In the first place, nutritionists were asked to give their considered opinion as to what amounts of food were needed in the United Kingdom to meet adequately the whole physiological needs of the human population, having regard to the dietetic habits of the British when unhampered by rationing. In the second place, a number of agricultural and fishery authorities, having been given a preview of the nutritionists' requirements, were invited to say how far British food resources could reasonably be developed to meet these requirements. The present alarming situation, when even minimal nutritional needs, despite the utmost austerity of rationing, are far from secure, was unforeseen when the conference was planned, but lent a sombre interest to the proceedings. One of the speakers remarked that though it was not on the agenda of the conference, an important and urgent question for discussion in the near future should be what we could do, having the new stringencies in mind, to meet from the agricultural and nutritional points of view a situation in which home production of food plus what Britain could buy with her failing credit from overseas threatened to be not merely below reasonable physiological needs, but even below minimal nutritional requirements for health and work.

In the first paper, Dr. E. R. Bransby, Dr. H. E. Magee, Mrs. M. C. Bowley and Miss B. R. Stanton gave a careful estimate, on the basis of the needs of the various age-groups in the population, of the amounts of different foods required to meet the requirements for calories, proteins and calcium of the whole population of the United Kingdom, both at the 1946 population of 48 million, and at the estimated 1964 population of 50 million (which would have a different age-group composition). They calculated these requirements on the amounts of food needed to enter the retail stage of distribution, not those actually eaten. The calories entering the retail stage are, in fact, some 10–15 per cent higher than those actually consumed, as determined by careful nutritional surveys—a gap for which, as yet, there is no adequate explanation.

The changes between the requirements as stated by Bransby *et al.* and actual pre-war supplies entail an increase of 48 per cent in milk and dairy products, of 56 per cent in potatoes and of 27 per cent in vegetables. Sugar needs are, however, below the pre-war level by 14 per cent, and the needs for fruit, fats, grain, meat, pork and eggs about the same as the pre-war level. It was stated that the diets as given provide not only all the physiological requirements for calories, proteins and calcium, but also those for all the other known nutrients. As regards protein, though for most age-groups more than half the total requirements were provided by animal protein, the authors thought that no clear evidence exists as yet as to what is the optimal amount of animal protein needed for a human dietary at different ages.

The discussion on the estimates given by Bransby *et al.* was opened by Mr. F. le Gros Clark. He doubted whether the menus which the first speakers had tabulated were really typical for those of the majority of the population of Great Britain. A good deal of our animal protein comes at present, and will continue to come, from milk, and he considered that the milk products/meat ratio should be increased. In estimating future requirements for the different types and qualities of food it is, of course, necessary to assume that the present relative prices will be maintained; but nevertheless, over even a short period of years, changes would undoubtedly take place which would greatly affect the demand for, and the consumption of, many items in the diet. In absence of rationing, and in view of the probable continuance of a high rate of employment and of wages, and of increasing education of the public in nutritional matters, he considered that it is highly probable that the demand for some of the more nutritious and tasty foods would exceed the needs as given in the first paper.

Prof. John Beattie mentioned experimental work on the calorie requirements of German prisoners under sedentary and under physically more strenuous conditions. It was found that, after loss of weight on a meagre diet, an immediate rise in food intake does not permit of increased expenditure of working energy until after a lag period, during which the lost reserves are being built up again. His view was that the adult male age-group should receive an *average* of 3,500 calories, rather than the 3,000 that Bransby *et al.* considered sufficient.

Dr. E. C. Owen pointed out that the basis for the figures usually accepted for calcium requirements is not very secure. Individual requirements vary greatly. For various reasons, old people often get less calcium than they need. As regards the virtues of animal as compared with vegetable protein, he considered that the main factor is lysine, the irreplaceable amino-acid present in reasonable quantities in most animal proteins, but found to a much smaller extent in vegetable protein.

Dr. Isabella Leitch was dubious as to the basis of some of the previous estimates of food requirements. The right method is to draw up adequate menus for the whole population, and calculate total food needs on that basis. She could offer no satisfactory explanation of the gap of 10 per cent or more between 'food entering retail consumption' and that actually consumed in the house. This apparent wastage, however, varies greatly from one food to another. In the case of milk it is small. In estimating calorie requirements for the adult working population, little more than a guided guess is at present possible, since the actual physical work done is so difficult of assessment.

If the gap between the estimate of food production plus imports and actual food consumption were as small as 10 per cent, Prof. J. R. Marrack thought that those making this estimate were to be congratulated. His view was that the average calorie requirement of adult male sedentary workers was usually appraised at too high a figure.

Dr. Wood suggested that three tables of food needs might be prepared: (1) the minimum nutritional requirements for health; (2) the requirements from the popular point of view, where items like sugar would be high; (3) the requirements if food were given away free.

In replying to these comments, Dr. Bransby stated that the diets suggested by himself and his colleagues were intended to be appreciably above the minima, and, in fact, at the 'comfort' level.

The first paper to approach the question as to how far the nutritionists' requirements could be met from home production was given by Dr. E. T. Jones, who dealt with wheat, potatoes and sugar-beet. He considered that by increased efficiency and more intensive management, yields per acre of wheat and sugar-beet could be fairly rapidly increased to provide from home sources fully 50 per cent of the total needs of Britain for bread grains and sugar. Such an increase would depend on the liberation of more than 680,000 acres from potato production. This could be achieved, and our potato crop still meet national requirements, if cultural technique were improved, by the application of existing knowledge, to give an average yield of 10 tons of potatoes per acre.

In the second paper, dealing with home production of milk and dairy products, Prof. H. D. Kay stated that to satisfy the nutritional requirements of Britain for liquid milk alone would entail an increase of about 25 per cent above our present annual total of some 1,360 million gallons of milk leaving the farm. He considered that, without any increase either in numbers or quality of our existing dairy cattle, a 10 per cent increase in milk coming off farms could be achieved if 400,000 tons of concentrated feeding stuffs, in addition to the quantity grown or imported at present, could be provided. This represents only 6 per cent of our pre-war total import of concentrates. The remaining increase of about another 15 per cent in the milk coming off farms could be attained by improving the genetic quality of the dairy cows—but without any increase in their present numbers—by artificial insemination from bulls of the quality now in use in cattle-breeding centres. At present rates of progress in the development of artificial insemination, this would take some ten years. Additional feeding-stuffs would, of course, be needed *pari passu* with the increase in potential milk-yields of the improved stock. He also emphasized that the technical skill both of the dairy farmer and his cowman would have to increase at the same time as his stock was improved, if full use was to be made of the effect of artificial insemination from high-class bulls.

Dr. J. Hammond discussed the difficult question of increasing the home production of meat (beef, mutton and pig meat) despite the simultaneous demands for home-produced and imported feeding-stuffs which increased milk production and egg and poultry production would make. The total needs of meat, according to the nutritionists' requirements, are some 146 lb. per person per annum, of which only 38 lb. is at present produced in Great Britain. More beef might be produced at home by using good beef bulls, kept at artificial insemination centres, on the poorer milk-producing cows, to give colour-marked progeny that would not be mistaken for dairy animals. More winter feed for both beef cattle and sheep would be needed if meat production were to increase. As regards pig meat, any large increase would depend almost entirely on a rise in the supply of feeding-grain from abroad, though something could be done if more farms kept a few extra pigs which might act as scavengers and need relatively little food from outside the farm.

The possibility of increased fish supplies was considered by Mr. R. J. H. Beverton and Mr. G. C. Trout. The danger of over-fishing the North Sea was pointed out. It is considered that increased supplies of cod and other fish could be obtained from more distant fishing grounds, but this might entail the use of factory ships, since storage difficulties on the ocean-going trawlers are very great. As regards herring, there is no evidence whatever of an approach to the stage of depletion of reserves—many more could undoubtedly be caught fairly close to the British Isles. Here the difficulty is to dispose of the catches obtained in the peak period, by suitable methods of preservation. Increase of supplies of fish other than the herring undoubtedly lies in the exploitation of the more distant fishing grounds, and a 40 per cent increase in supplies is a possible attainment in a few years.

Egg production was discussed by Mr. E. T. Halnan. If larger quantities of suitable feeding-stuffs could be provided, he foresaw little difficulty in producing the increase of some 6,000 million eggs called for by the nutritionists. But with the greatest possible production of wheat and barley at home, and with a change in the rate of extraction of flour from the present 85 per cent down to the pre-war 70 per cent—neither of which seems likely—at least 368,000 tons of imported feeding-stuffs would be needed. From the figures he gave for present egg production, it appears that an unduly large number of eggs, apart from those legitimately produced by the 'backyard poultry keeper', are evading the official rationed channel at present.

The general discussion was opened by Dr. W. K. Slater. He emphasized that the additional production of food from sources in Great Britain means increased supplies of materials, for example, for additional factories and plant for extracting sugar-beet and for housing poultry. The training of the human element in more efficient methods of cultivation and of management of stock is likely to be a formidable task. He asked whether a true appreciation of the immediate future position in Great Britain is rather that the number of calories per person and the nutritional value of the average diet generally are much more likely to fall than to rise; and how far this fall could go without acute sequelæ.

Dr. N. C. Wright considered that a matter of immediate importance is the prevention of wastage, from whatever cause, of food already produced. We must find out, for example, exactly what happens to the 10–15 per cent of calories that vanish as between food 'moving into consumption' and food actually consumed in the household. He believed there is no escape from a greatly increased importation of animal feeding-stuffs from overseas if home-produced human food is to increase.

The importance of disease control and the part that the veterinary profession could play in preventing wastage were emphasized by Dr. W. R. Wooldridge. Prof. J. R. Marrack inquired whether, if the amount of milk required per head per day by the nutritionists has to be produced as liquid milk during the *winter* months, it would not thereby entail a considerable excess to liquid requirements at the production peak during spring and summer, which excess could provide a substantial quantity of dairy products.

Prof. A. W. Ashby, in summing up, said that we should face the fact that the standards in Great Britain for human food have been reduced to, and are likely to remain for some time, those of a rather poor peasant population. He considered that more co-ordinated consultation between the experts in nutrition and in food production and the administrative authorities is needed to give a sound basis both for the planning of increased food production at home and the carrying of these plans into effect. He criticized some of the figures given by those who had spoken during the conference on the possibilities of increased agricultural production, and thought that more statistical wisdom and mutual consultation might have made their estimates more helpful. He was very doubtful whether the yields per acre of wheat, etc., that one of the speakers had assumed as attainable in the near future, could, in fact, be reached. Competing requirements for feeding-stuffs to provide milk, meat and eggs have to be regarded from the point of view of efficiency of conversion of feeding-stuffs to human foods. Here the dairy cow is far superior to the bullock. He emphasized that under an effective system of price control the *relative* prices offered to the producer for the different farm products is the main directive factor in influencing relative volumes of farm output.

The chairman, in conclusion, mentioned the surprisingly large total tonnage, relative to the tonnage of human food, that is needed to feed the animal population of Great Britain, and emphasized the importance and economy of producing the maximum quantity of feeding-stuffs at home by the intensive application of existing knowledge.

The proceedings of the conference will be published in an early number of the *British Journal of Nutrition.*

OBITUARIES

Prof. J. Masson Gulland, F.R.S.

It was with a sense of severe personal loss that his many friends learned of the untimely death of Prof. J. M. Gulland, who was a victim of the railway accident at Goswick on October 26. He was a leading figure in the chemical world, a pioneer worker in several important fields of organic chemistry and biochemistry, and a man of outstanding personal charm.

John Masson Gulland was born in Edinburgh in 1898 and was the only son of the late Prof. G. Lovell Gulland, professor of medicine in the University of Edinburgh. Gulland was much devoted to his native land, and above all to his native city, which he frequently visited. He was educated at Edinburgh Academy and the University of Edinburgh, where he graduated in 1921, after serving as a second lieutenant in the First World War. At that period it was natural for a graduate of a Scottish university with an interest in organic chemistry to turn his eyes towards St. Andrews, and, having been awarded a Carnegie Scholarship, Gulland went there to work under Prof. (later Sir) Robert Robinson, whom he rejoined in Manchester and again later in Oxford. Gulland became a University demonstrator in chemistry at Oxford in 1924, and was appointed lecturer in chemistry at Balliol College in 1926. These appointments he relinquished in 1931, when he became senior assistant in biochemistry at the Lister Institute, London, and a reader in biochemistry in the University of London. In 1936 Gulland was appointed to the Sir Jesse Boot Chair of Chemistry at University College, Nottingham, which post he resigned in September of this year in order to take up a new appointment as director of research to the Institute of Brewing. This position had been vacant since the death of Sir Gilbert Morgan in 1940, and in reviving the post the Institute of Brewing planned to expand its research activities and to set up its own central research laboratories. At the time of his death, Gulland had already begun to apply himself with his customary vigour and enthusiasm to the execution of these plans. He was married in 1924, and is survived by his wife and two daughters.

Although he has a large amount of first-rate scientific achievement to his credit, Gulland was not quite so prolific a contributor to the original literature as some of his contemporaries. This is partly due to the formidable nature of the problems which he tackled; he never engaged in trivialities. It is probably due also to the fact that his earlier ardour for work at the bench tended to be subordinated later to his interest in organisation and administration, for which he had a real flair. He served on the councils of the Chemical Society and the Royal Institute of Chemistry, and was an honorary secretary of the Chemical Society during 1933–36. From 1932 until 1934 he was secretary of Section B of the British Association, and during 1935–37 he was recorder to the Section. During the early years of the Second World War he was senior gas adviser to the North Midland Region of the Ministry of Home Security, and during 1943–44 he was assistant director, Chemical Research and Development, Ministry of Supply. In this capacity he was attracted by the potentialities of alginic acid as a chemical raw material, and he took an important part in the establishment of the Scottish Seaweed Research

Association, the new laboratories of which in Musselburgh, Midlothian, were formally opened in September (see *Nature* of November 15, p. 662); Gulland was a member of the Board of Management of this Association, and chairman of its General Purposes and Chemical Advisory Committees. His department at Nottingham was a model of efficient organisation, and was well equipped for the researches which were carried out there under his inspiration and guidance. He had in recent years planned and supervised the erection of excellent extensions to the laboratories, and these are now playing a valuable part in meeting the heavy demands of the post-war period.

Only the barest reference is possible here to Gulland's scientific work, an appreciation of which will doubtless be published elsewhere. During his St. Andrews and Manchester days, he worked on the morphine group of alkaloids, and the constitution which is now generally accepted for morphine was first adumbrated in two classical papers, published in 1923 and 1925, by Gulland and Robinson. With R. D. Haworth, Gulland published a series of papers on the aporphine group of *iso*quinoline alkaloids (1928–29). New methods were devised by which were synthesized, among other compounds, bulbocapnine methyl ether and corytuberine dimethyl ether. Gulland also made other chemical studies of compounds of biological interest, including pellitorine, the pungent principle of *Anacyclus pyrethrum*, and the active constituents of *Taxus baccata* (1930–31). His work then followed a more biochemical trend and he investigated (with R. A. Peters) the reducing substances of pigeon's blood, and carried out a series of investigations on the oxytocic principle of the pituitary gland (1932–35), elucidating something of the chemical nature of this hormone. His major contributions to science are those carried out during the past twelve years on the chemistry of the nucleic acids, and of the nucleotides and nucleosides from which they are built up. Some of this work was summarized by Gulland in his Tilden Lecture given before the Chemical Society in 1943 (*J. Chem. Soc.*, 208; 1944). The pre-eminent part which the nucleoproteins play in the fundamental processes of life has become increasingly apparent in recent years, and gives added significance to Gulland's investigations in this field. It is a great misfortune to biological science that they have been so abruptly terminated.

J. W. COOK

WE regret to announce the following deaths:

Prof. W. S. R. S. Lewis, professor of geography at the University College of the South-West, Exeter, on November 14.

Prof. Frank R. Lillie, emeritus professor of embryology in the University of Chicago, president during 1935–39 of the U.S. National Academy of Sciences.

Mr. W. J. U. Woolcock, C.M.G., C.B.E., a past-president of the Society of Chemical Industry, on November 13, aged sixty-nine.

NEWS and VIEWS

Nobel Prizes for 1947

Sir Robert Robinson, F.R.S.

THE award of the Nobel Prize for Chemistry for 1947 to Sir Robert Robinson, president of the Royal Society, can have occasioned little surprise in view of his outstanding contributions to organic chemistry. They cover so wide a field that it is only possible to refer to a few of the more important of these. His early work on brazilin and hæmatoxylin, carried out in collaboration with the late Prof. W. H. Perkin, led to new pyrylium salt syntheses, which were later extended and applied to the artificial preparation of the anthocyanins, the chief red and blue pigments of flowers and blossoms, thus providing a final proof of the structures assigned to some of them by Willstätter. The possession of the pure synthetic specimens made it possible to devise simple quick tests for the anthocyanins contained in a few petals, which have proved to be of great value in genetic investigations. Of equal brilliance are his investigations in the alkaloid field. His simple synthesis of tropinone was rather the outcome than the cause of a theory of biogenesis of plant products put forward in 1917. This theory collated for the first time the apparently dissimilar alkaloidal constituents, and it has proved useful both in prediction and in criticism. The structures put forward for morphine and thebaine have found general acceptance. Undoubtedly his greatest contribution in this field has been his extended study of the chemistry of strychnine and brucine.

Sir Robert's mastery of the synthetic method and his penetrating insight is revealed in the long series of memoirs on the synthesis of the steroids. His work in this field has led, in collaboration with Prof. E. C. Dodds, to the synthesis of stilbœstrol, a useful and active œstrogen, which has found application in the treatment of certain forms of cancer. During the recent War he was the leader of the Oxford team engaged on the chemistry of penicillin, and it was in his laboratory that the main facts of its constitution were first elucidated. Finally, mention must be made of his contributions to the electronic theory of organic reactions. This theory was based originally on the discovery of C-alkylation of substituted aminocrotonic esters and was later extended by many other observations. Robinson's theoretical views, developed during the decade 1920–30, were subjected to severe criticism, but they have survived in almost unmodified form and they have now found general acceptance. It is not too much to say that the system first advanced by Robinson and his collaborators is the basis of the modern chemistry of organic chemical reactions. Robinson and his school have exercised a profound influence on the development of organic chemistry, not only in Great Britain but throughout the whole Commonwealth. Many of his former students and collaborators hold university professorships or fill important positions in chemical industry.

Sir Edward Appleton, G.B.E., K.C.B., F.R.S.

THE announcement of the award of the Nobel Prize for Physics for 1947 to Sir Edward Appleton is one which will be received with great satisfaction by scientific men everywhere, and particularly by workers in pure and applied physics. Sir Edward

Appleton has achieved renown in two spheres, either of which might be considered as forming a sufficiently full life for a lesser man of science. He has for more than a quarter of a century been the most active worker in the field of radio physics, and during this period he has conducted research work of the most far-reaching importance. Since 1939, also, he has been secretary of the Department of Scientific and Industrial Research, a position which gives him the responsibilities and duties of the leading man of science in the Government service of Britain. Appleton displayed his great scientific ingenuity and experimental skill in December 1924, when he demonstrated the existence of the Heaviside layer as an ionized region of the atmosphere capable of reflecting electromagnetic waves. Shortly afterwards, he discovered another and higher region—the Appleton layer—from which the shorter radio waves are reflected after they have penetrated the lower region. From that time onwards Appleton has conducted a continuous series of researches on the characteristics of the ionosphere, and the part they play in determining the mode of propagation of radio waves round the earth. The techniques developed in the course of these investigations provided the foundations for the development of radar in Great Britain, while the results of the research on the ionosphere have proved invaluable in forecasting and allocating the most suitable frequencies for practical radio communication, broadcasting and other applications. More recently, Sir Edward Appleton, in co-operation with other workers, has devoted attention to the reflexion of radio waves from meteors, and has demonstrated that sunspots are powerful sources of very short radio waves.

His work during the war years as secretary of the Department of Scientific and Industrial Research was particularly onerous for, in addition to conducting the normal activities of the Department, he was called upon in 1941 to advise the Government on the magnitude of the effort to be devoted to the exploitation of nuclear energy, and later to set up a special section of the Department to carry out the necessary research work forming the British contribution to the development of the atom bomb. Sir Edward, who was elected a fellow of the Royal Society in 1927, has received many honours and awards in Great Britain and overseas, and he has been president of the International Scientific Radio Union since 1934.

Royal Society: Medal Awards

His Majesty the King has approved the recommendations made by the Council of the Royal Society for the award of the two Royal Medals for the current year as follows:

Prof. C. N. Hinshelwood, Dr. Lee's professor of chemistry, University of Oxford, for his distinguished work on the mechanism of chemical reactions, from the simplest gas phase processes to the complexities of cell division;

Dr. F. M. Burnet, director of the Walter and Eliza Hall Institute for Medical Research, Melbourne, for his distinguished work on bacteriophages, viruses and immunity; and for his contributions to the study of infectious disease as an ecological phenomenon.

The following awards of medals have been made by the President and Council of the Royal Society:

Copley Medal to Prof. G. H. Hardy, emeritus professor of pure mathematics, University of Cambridge, for his outstanding part in the development of mathematical analysis in Britain during the last thirty years;

Davy Medal to Prof. L. C. Pauling, director of the Gates and Crellin Laboratories, California Institute of Technology, for his distinguished contributions to the theory of valency and for their application to systems of biological importance;

Buchanan Medal to Sir Edward Mellanby, secretary to the Medical Research Council, for his distinguished researches on the physiology of nutrition, especially in relation to the causation of deficiency diseases;

Hughes Medal to Prof. J. F. Joliot, director of the National Centre of Scientific Research, Paris, for his distinguished contributions to nuclear physics, particularly the discovery of artificial radioactivity and of neutron emission in the fission process.

Physiology at St. Thomas's Hospital Medical School: Prof. H. Barcroft

Prof. Henry Barcroft, Dunville professor of physiology, Queen's University, Belfast, has recently been appointed to the University chair of physiology in St. Thomas's Hospital Medical School, London. Prof. Barcroft is a son of the late Sir Joseph Barcroft of Cambridge, and was educated at Marlborough College and King's College, Cambridge. He held the Harold Fry and George Henry Lewis studentships at Cambridge during 1927–29 and was awarded the Gedge Prize in 1930. He qualified in medicine at St. Mary's Hospital, London, after which he was appointed lecturer in physiology at University College, London, a post which he occupied from 1932 until 1935. He has held the chair of physiology at Queen's University, Belfast, from 1935 until the present time, and has carried out distinguished work on the control of the vasomotor system, and of the blood flow to the limbs and other parts of the body. His experiments were mainly carried out on the human subject and involved important observations on the physiology of syncope.

Jubilee of the Discovery of the Electron

The fiftieth anniversary of the discovery of the electron was recently marked in Cambridge by an open meeting of the Philosophical Society at which a lecture on the history of the Cavendish Laboratory was given by Dr. Alex. Wood in that Laboratory. Dr. Wood was himself a research student under Sir J. J. Thomson and has been closely associated with the teaching work of the Cavendish Laboratory since 1905. His lecture was illustrated by exhibits of historical apparatus used by Clerk Maxwell, Rayleigh, Thomson and Rutherford. Among guests present were Dr. G. F. C. Searle, who as a boy was shown round the Laboratory by Clerk Maxwell shortly after it was built; Mr. J. E. Rolph, who was appointed as laboratory assistant by Lord Rayleigh in 1881; Mr. F. J. Lincoln, who was a laboratory assistant for fifty-three years, including forty-two years as steward; Sir William Dampier, who as W. C. D. Whetham joined the Laboratory in the very early days of Sir J. J. Thomson's professorship; and Lady Thomson, who as Miss Paget was a research student in 1889 and was married to J. J. Thomson in 1890.

British Books for Germany

At the Information Centres of the Control Commission in the British Zone of Germany reference books are available for those who live near enough;

and special arrangements are planned for educationists and writers of school and university text-books. British books cannot, however, be purchased by Germans. The Control Commission has officially approved a scheme, put forward by the Agency for Intellectual Relief in Germany, under which the Agency will establish lending libraries for British books in key-centres of the British zone. The first library, containing some four thousand books, is being opened in Hamburg. Once the libraries have been established, German committees in each town will take over the management; it is expected that current expenditure in Germany will be covered by the borrowers' fees. A list of books needed, based on suggestions by German readers, has been prepared. Contributions are solicited towards the cost of books that must be bought; cheques should be sent to the honorary treasurer of the Agency for Intellectual Relief in Germany, C. P. Kininmonth, 4 Chapel Row, Wheeler End, High Wycombe, Bucks. Information relating to the scheme can be obtained from the Agency for Intellectual Relief in Germany, Foreign Office, German Section, 48 Prince's Gardens, London, S.W.7.

Import of Scientific and Technical Books

REPLYING to a question in the House of Commons, the President of the Board of Trade stated that he is prepared to consider the issue of licences for limited additional imports of technical and scientific books in English from certain European countries. Similar books in foreign languages from non-English speaking countries are licensed freely.

German Hydrographic Institute, Hamburg

THE first annual report of the German Hydrographic Institute, Hamburg, consists of a 64-page booklet both in German and English (the former language being that of the official text). It gives a good account of the provision which has been made in Germany since the War for the performance of the various tasks formerly undertaken by the organisation which was the German analogue of the Hydrographic Department of the British Admiralty. Along with that account, which tells of work to do with marine surveying, the making and printing of nautical charts, the issue of nautical books, the testing of compasses, the observation and publication of magnetic values, the issue of time signals, and with many other matters concerning which information is needed by mariners and required by the naval side of the Allied occupying authority, there is substantial information bearing upon the present state of German oceanography.

Before the War, the science of oceanography had numerous practitioners in Germany, and, in addition to the two well-known and very large organisations devoted to its furtherance, there were several small scientific bodies of repute which worked in this sphere. The report records how plans were laid for the employment of about one-fifth of the large number of oceanographers to work upon tasks which should serve the interests of, and meet the needs of, that rump organisation which—it was approved by the Allied Control Council—had to be set up to carry out essential hydrographical duties in German waters. These scientific workers ultimately became Section 2 of the Institute which is the subject of the report. This, established initially by the British naval authorities, is now under the governance of a quadripartite board of four directors, functions in Hamburg, and is 'managed' by the British director, who is a captain in the Royal Navy. Considerable information is given concerning reports which have been written by various German marine scientific workers since the capitulation, and it is expected soon to start upon the issue of a periodical wherein such reports will be printed for circulation.

National Foundry College

THE National Foundry College has been established and its board of governors nominated by the Minister of Education. The College will be housed in, and work closely in conjunction with, the Wolverhampton and Staffordshire Technical College. The board of governors is charged with the responsibility for providing national facilities for foundry education and research, in the form of full-time courses, vacation courses, refresher courses, and the like, and also for providing regional and local facilities for full-time, part-time day and evening courses, to cover the whole range of foundry education. Its first task will be the re-establishment of the full-time diploma course which was the main feature of the predecessor of the College, the British Foundry School, during 1935–39. This course will normally run for an academic year, and the first session opens on January 5. The course will cover the whole of the foundry industry, ferrous and non-ferrous, including grey, white and chilled iron castings, malleable castings, steel castings, and castings in non-ferrous metals, such as alloys of copper, tin, zinc, nickel, aluminium and magnesium. The diploma awarded to successful students will be endorsed by the Ministry of Education. There is no upper age limit for admission; a minimum of one year's practical experience in at least one branch of the industry will be required, together with a Higher National Certificate or a university degree, preferably in metallurgy or engineering, or a grade of membership obtained by examination of a professional institution in engineering, metallurgy or chemistry. Mr. J. Bamford, who was in charge of the British Foundry School during 1935–39, and who has since held important managerial appointments in the industry, has been appointed head of the National Foundry College.

Abstracts on Powder Metallurgy

HITHERTO available in private circulation only, *Metal Powder Report* is now issued at an annual subscription of £3 7*s*. 6*d*. The report is a sixteen-page monthly abstract journal dealing solely with the production, treatment and use of metal powders, under the joint editorship of W. D. Jones and R. A. Hetzig. The use of such products in electronics, the metallization of glass and ceramic materials, iron driving bands, porous aluminium-base bearings, electrical contacts, magnetic materials, sintered plates for batteries, sparking plugs, and stainless steel powders for paints and lacquers, all of which are mentioned in the issues for September and October 1947, will give an indication of the surprising breadth of interest of this very new branch of metallurgy. All concerned with powder metallurgy in any of its aspects will find this publication of real use. It is available from Powder Metallurgy, Ltd., Commonwealth House, 1–19 New Oxford Street, London, W.C.1.

Biological Abstracts

A NEW section of *Biological Abstracts* (University of Pennsylvania, Philadelphia) will be published as from January 1948. The section (*J*—Abstracts of

Cereals and Cereal Products) will appear monthly except during the four summer months, when it will be bi-monthly. It will bring together abstracts of the entire technological and scientific literature on the cereal grains—wheat, corn, rye, oats and barley—and on all other grains such as soya bean, cottonseed, buckwheat, etc., utilized by the milling and food industries. It will include contributions on plant breeding, cultural practices, varieties, soil and weather relations of the crops; physiology, diseases, insect pests; storage of grain and flour; milling machinery and techniques; plant sanitation; baking and nutritional studies on diets in which cereal and related products are important components; biochemistry of cereals and cereal products; enzymes; and industrial microbiology in so far as it affects the cereals and their products.

U.N.E.S.C.O. Fellowships

THE first two of the fellowships placed at the disposal of U.N.E.S.C.O. by the American Chemical Society have been awarded to men of science from Czechoslovakia. The successful candidates are Dr. Milos Hudlicky, assistant at the Institute of Organic Chemistry at Prague, and Dr. Ivan Vavruch, assistant at the Research Institute of the Czechoslovak Sugar Institute, also in Prague. It is hoped that both the new fellows will be able to take up their appointments early in 1948. One of the fellowships offered by the Belgian Ministry of Education under the same U.N.E.S.C.O. scheme has been awarded to Mr. Charalambos Vacalopoulos, who is studying international relations in Brussels. The organisation of a programme of fellowships of this kind is one of the most important of the aims of U.N.E.S.C.O., as it is designed to make it possible for scientific workers, teachers and others from war-devastated countries who were cut off from the outside world during the War to be made acquainted with the most recent developments in the field of their specialization.

Conference on Ethics and Science

IN July last year the British Social Hygiene Council held a conference on "The Problems of Communal Life: the Ethical and Scientific Approach", which proved so successful that the Council was asked to arrange something similar this year. In response to this request, a one-day conference has been arranged for December 4, and will take place in the Livingstone Hall, Tothill Street, Westminster, S.W.1. Its main theme will be "Society and the Individual", which will be considered under two headings, namely, "The Values Society sets upon the Individual", and "The Values the Individual sets before Himself". Ample time will be allowed for discussion at the end of both the morning and afternoon sessions and at an open meeting in the evening. Once again the aim of the Conference is to effect, in some measure, a synthesis between the spiritual and the scientific interpretations of life. The chair will be taken by Prof. Winifred Cullis and Dr. E. B. Strauss, and the speakers include Mr. L. J. F. Brimble, Father Leycester King, Canon Marcus Knight, Dr. E. H. Larkin, Mr. J. Mackay-Mure, Dr. Mary Smith, Mrs. Joan B. Thompson, Mr. Kenneth Walker, and Mr. R. Weatherall. Further information and tickets (members of the Council 2*s*. 6*d*., others 3*s*. 6*d*.) can be obtained from the British Social Hygiene Council, Tavistock House North, Tavistock Square, London, W.C.1.

Royal Society of Edinburgh: Officers for 1947–48

AT a statutory meeting of the Royal Society of Edinburgh, held on October 27, the following officers and members of council were elected: *President*, Sir William Wright Smith; *Vice-Presidents*, Lord Cooper, Prof. J. W. Heslop Harrison, Prof. W. M. H. Greaves, Lieut.-Colonel W. F. Harvey, Prof. James P. Kendall, Sir Ernest Wedderburn; *General Secretary*, Dr. J. E. Richey; *Secretaries to Ordinary Meetings*, Prof. Arthur Holmes, Prof. E. T. Copson; *Treasurer*, A. W. Young; *Curator of Library and Museum*, Dr. John E. Mackenzie; *Ordinary Members of Council*, Prof. E. P. Cathcart, Prof. A. Gray, Dr. J. R. Greig, Dr. W. A. Harwood, Prof. C. M. Yonge, Prof. A. D. Hobson, Dr. W. O. Kermack, Dr. John Weir, Prof. J. H. Gaddum, Prof. G. D. Preston, Prof. S. J. Watson, R. Ll. Gwilt.

Announcements

THE Hanbury Gold Medal for 1947 of the Pharmaceutical Society of Great Britain was presented on November 13 to Dr. Hans Flück, professor of pharmacognosy in the Faculty of Pharmacy of the Federal Technical Institute, Zurich.

THE Pedler Lecture of the Chemical Society will be given by Sir Ian Heilbron, professor of organic chemistry, Imperial College of Science and Technology, London, at the Society's rooms on December 4 at 7.30 p.m. He will speak on "Recent Developments in the Vitamin A Field".

DR. W. J. KEARTON, senior lecturer in mechanical engineering in the University of Liverpool, has been appointed to the Harrison chair of mechanical engineering in the University.

MR. JOHN WILSON, director of research to the British Rubber Producers' Research Association, has been appointed director of research to the British Rayon Research Association.

SIR CHARLES ELLIS, president and chairman of Council of the British Coal Utilization Research Association, has announced the following new titles in respect of the directorate of the Association: Dr. D. T. A. Townend, director-general; Dr. D. H. Bangham, director of research laboratories; Dr. E. G. Ritchie, director of engineering laboratories; Mr. J. S. Hales, director of domestic appliance laboratories; Mr. H. T. Hathaway, secretary and finance officer.

THE film "Nagana", introduced by Dr. P. J. du Toit at a meeting held at the London School of Hygiene and Tropical Medicine to discuss "D.D.T. and the Aeroplane in the Control of the Tsetse Fly and Trypanosomiasis in South Africa" (see *Nature*, October 11, p. 485), is now at the South African Scientific Liaison Office, 39 Prince's Gate, London, S.W.7, and is available on loan to scientific bodies wishing to show it. It is a 16-mm. colour film with sound-track.

THE Boron Agricultural Bureau announces that its work will be brought to a close at the end of December 1947. Its comprehensive collection of literature on the uses and functions of boron in agriculture, which has been assembled during the last eleven years, will be presented to the library of the Rothamsted Experimental Station, where it will be available for consultation.

Origin of Cosmic Ray Stars at Sea-Level

IN an effort to identify the radiation responsible for production of the nuclear disintegrations and heavy charged particles occurring in the cosmic rays, we have carried out experiments with Ilford 'Nuclear Research' emulsions exposed on high mountains, and at sea-level with various absorbing materials. The results may be summarized as follows.

The ratio R of the number of single tracks to disintegration 'stars' has been measured at different altitudes, the plates and packing being identical in each case:

	Sea-level	12,000 ft.	14,500 ft.
Relative intensity of stars	1	10	20
R	26 ± 3	27 ± 2	$23{\cdot}5 \pm 2$

The constancy of R immediately suggests that the single tracks arise from stars produced in the material adjacent to the emulsion. This assumption is borne out by the fact that the proportion of single tracks attributable to alpha-particles and protons is, in fact, about what would be expected from the observed ratio in stars in the emulsion. Alpha-particles, with about one quarter of the range of the protons, produce some 7 per cent of the single tracks and 30 per cent of the tracks from stars.

On the above assumption, it is possible to calculate the value of R as follows. In examining a star in the emulsion, the identification of the disintegrating nucleus can, of course, only be based on the total charge carried by the emitted particles. It is thus found that the disintegration of a carbon, oxygen or nitrogen nucleus appears to be roughly eight times as probable as that of silver or bromine. Observations have therefore been made on the range and frequency distributions of tracks from stars produced by disintegration of the light or heavy emulsion nuclei respectively, and these data used to calculate the value of R when materials of various atomic number are in contact with the plates. (The thickness of the layer is assumed large compared with the mean range of the particles from stars, which is ~ 1 mm.) Making allowance for the effect of the glass of the plate, our results are as follows:

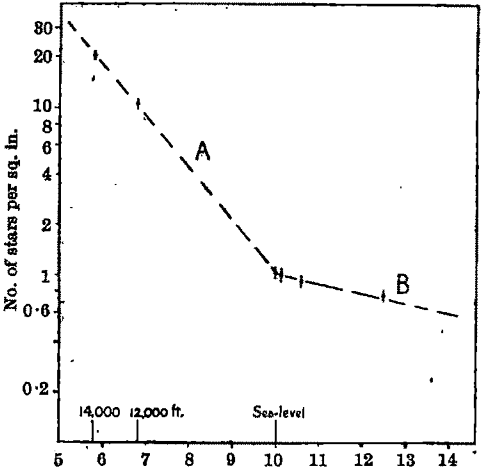
Covering material (1 cm. thick)	R (observed)	R (calculated)
Graphite	28 ± 2	~ 35
Paraffin wax	24 ± 2	~ 30
Brass	28 ± 4	~ 30
Lead	25 ± 2	~ 25

It is interesting to observe that there is no marked variation in the numbers of tracks with atomic number of covering material. Furthermore, the observed and calculated values agree as well as could be expected in view of the uncertainties in the calculation.

It can therefore be taken that the number of stars in the plate is proportional to the number of single tracks observed, and this fact has been used in order to obtain statistically significant results, in measuring the absorption coefficient of the star-producing radiation at sea-level. The variation in the number of single tracks (and hence presumably of stars) in plates exposed under different thicknesses of lead and paraffin wax was as follows:

Lead	Tracks per sq. in.	Paraffin wax	Tracks per sq. in
0·2 cm.	53 ± 5	1 cm.	49 ± 5
1 "	50 ± 5	5 "	56 ± 7
5 "	46 ± 5	17 "	51 ± 5
20 "	38 ± 3		

The data for single tracks under lead enables us to compare (see graph) the absorption of the star-producing radiation in a given mass of atmosphere (in metres of water-equivalent) with that in the same mass of heavy matter; clearly the former is much greater[1].



(*A*) ABSORPTION OF STARS IN THE ATMOSPHERE. (*B*) ABSORPTION OF SINGLE TRACKS IN LEAD

From the above facts, and the absolute intensity of stars (~ 1 per c.c. 'Nuclear Research' emulsion per day) and single tracks (~ 0·3 per sq. cm. per day) at sea-level, we can make certain deductions regarding the nature of the star-producing radiation.

Bagge[2] has attributed the stars to photons; but although the altitude variation of stars ($I = I_0$ exp ($- 1{\cdot}17h$), where h is in metres of water) is almost identical with that of the soft component, the cross-section for photonuclear disintegration would have to be $\sim 2 \times 10^{-25}$ cm.^{2} to account for the observed star intensity; this seems impossibly high. Further, the weak absorption in lead shows the star-producing radiation to be far more penetrating than photons. Heitler, Powell and Heitler[1] observed a 50 per cent increase in the intensity of the single tracks under lead at the Rossi maximum (1·2 cm.) on the Jungfrau, but the present experiments show that, if such an effect exists at sea-level, it is less than 10 per cent. It is also noteworthy that in cloud-chamber work[3] there has been a significant absence of correlation between stars and cascade showers. From these facts one concludes that photons produce only a small proportion (less than 10 per cent) of the stars.

It has also been suggested that neutrons are largely responsible for the stars. It will be seen from the table, however, that covering the plates with layers of hydrogenous material does not noticeably increase the number of single (proton) tracks, and a similar effect is observed at high altitudes. We are thus able to fix an upper limit to the flux of fast neutrons across the plates, and find it to be less than half per cent of the total radiation at sea-level. Assuming the capture of fast neutrons to be responsible for nearly all the stars, this in turn puts a lower limit to the cross-section for this process. One finds $\sigma \geqslant 2 \times 10^{-24}$ cm.^{2}, which appears quite irreconcilable with the small absorption coefficient in lead. We therefore conclude that neutrons cannot account for more than about 10 per cent of the stars.

Although it is almost certain that several different types of radiation play a greater or lesser part in star production, the rapid absorption of this radiation in the atmosphere, as compared with dense matter, strongly suggests that a large proportion of the disintegrations are initiated by unstable particles undergoing radioactive decay in free space. Again, in cloud chamber experiments, events in which charged particles produce stars are comparatively rare. Furthermore, the intensity of charged mesons appears to increase only slowly with altitude. It is therefore probable that the particles responsible for the stars are uncharged.

The only reasonable alternative is to suppose that the star-producing radiation at high altitudes is quite different from that at sea-level.

I am indebted to Prof. L. Leprince-Ringuet for kindly exposing the plates at high altitudes, and to Sir George Thomson for valuable discussions and advice.

Solar Radio-Frequency Noise Fluctuations and Chromospheric Flares

Martyn[1] and Shklovsky[2] have suggested that plasma oscillations in the corona may provide a source of radio-frequency radiation. It has also been shown that radiation of a few metres wave-length must originate at heights above the chromosphere of the order of a solar radius.

If the plasma is excited by ultra-violet radiation, noise fluctuations should occur simultaneously with flares. If corpuscular emission is responsible, the radio noise should be observed later than the flare by an interval dependent on the average velocity of the corpuscles and the height at which the oscillations are excited.

Observations of radio noise at 75 Mc./s. made here during the past few months, combined with solar flare and radio fade-out data made available by the Commonwealth Observatory, Canberra, and the Watheroo Magnetic Observatory, provide the instances, collected in the table, of a delay of the right order between chromospheric disturbance and noise bursts.

The disturbances of 16.5.47, 4.6.47 and 5.6.47, described as 'violent', consisted of numerous bursts with a very high flux-level and a duration longer than the usual noise storm.

During the same period, and within the interval (02.00–06.00 G.M.T.) of observations at Perth and the half-hour preceding, five flares of importance 0–1 and three noise storms considered to be associated with simultaneous (but unobserved) chromospheric disturbances were reported from Canberra and three minor fade-outs from Watheroo. No radio noise was observed in connexion with these disturbances.

Appleton[3] and Allen[4] have observed noise fluctuations occurring simultaneously with flares or fade-outs. Appleton's observations were made at a time when the quasi-steady background flux was abnormal, that is, when the plasma was continuously excited. In such conditions ultra-violet radiation might be more effective. Allen's observations, made on 200 Mc./s., apply only to a proportion of flares and bursts and are not inconsistent with those tabulated here.

Some time ago[5], I reported observations of violent fluctuations in solar noise flux (03.14–29 G.M.T. on 2.8.46) at the same time as an eruptive prominence was seen at Watheroo to develop and fade on the solar limb. Since the Watheroo observations did not begin until 03.15 G.M.T., the possibility exists that the initial flare occurred sufficiently beforehand for corpuscular emission to have been responsible for the radio noise. On that occasion there was no fade-out, but another noise disturbance on 2.8.46, observed during 04.51–7 G.M.T., was preceded by a fade-out at 04.45, observed to be connected with another disturbance in the same region of the sun. Since the origin of the noise radiation is thought to be high in the corona—probably exceptionally high over the large sunspot group then on the limb—it would appear that serious absorption of the radio-frequency radiation did not occur in the direction pointing to the earth at that time, although normally conditions would

Date	Chromosphere		Radio noise (Perth)

Photo-electric Fourier Transformer and its Application to Sound-Films

At the time of the publication of the accounts by Born, Fürth and Pringle[1,2] of the new instrument named by them the 'photo-electric Fourier transformer', we happened to be engaged in constructing a very similar instrument here. The principle of the apparatus and the main essentials of its design had been worked out by one of us (D. B.) in continuation of earlier work on acoustic spectra from sound-films; it seemed probable that the method would have advantages over the diffraction method previously employed[3].

Between our arrangement and that of the above authors the only significant differences are as follow. (*a*) We do not employ masks or silhouettes representing the functions to be analysed, as it has always been our aim to use actual sound-film. (*b*) Instead of producing the Fourier transforms of given functions singly, we seek to produce a continuous or running analysis as one function changes by gradual transitions into another. Our apparatus, therefore, includes a provision for moving the record of the function A (that is, the sound-film) steadily past the optical aperture, and simultaneously moving the photographic film B upon which the transformed function is recorded or transcribed. (*c*) The signals from the photocell are employed to give intensity modulation on the oscillograph screen instead of amplitude modulation; this is necessitated by (*b*) above. (*d*) In view of the fact that the higher audio-frequencies are registered on a sound-film as extremely fine periodicities indeed, we employ a grating with a greater number of more closely spaced elements; our grating is in the form of a disk 6 in. in diameter with 55 elements to the inch.

In other respects, such as the general arrangement of the disk, slit, photocell and oscillograph, and the use of a harmonic time-base synchronized electromagnetically with the rotating disk, our method coincides surprisingly closely with that of the above authors.

Early attempts to produce a satisfactory disk were made during the war period, but the work had then to be abandoned for more urgent matters. Shortly after the project was resumed, the paper of Born, Fürth and Pringle appeared, but we continued our work as we had a somewhat different object in view in constructing the instrument. Incidentally, when this is to be used to analyse actual sound-film, the requirements of the optical and amplifier systems become very stringent, presenting problems which could not be overcome immediately. The accompanying photographs show, however, that it is possible, using this apparatus, to display sound in the desired way. When a film record of speech sound is subjected to analysis, a succession of frequency-versus-time patterns is obtained, of the type illustrated by Fig. 1, which represents the word 'there', containing the diphthong ɛ + ə. From previous knowledge, the acoustic spectrum would be expected to show a considerable number of harmonics of the vocal-cord pitch, with certain of the harmonics augmented in intensity by the resonances of the vocal cavities, and we find these characteristics clearly brought out in the photograph. Some pre-distortion in favour of the higher frequencies was employed during recording, and for this reason, and because of its low natural intensity, the fundamental pitch itself is not registered in this trace.

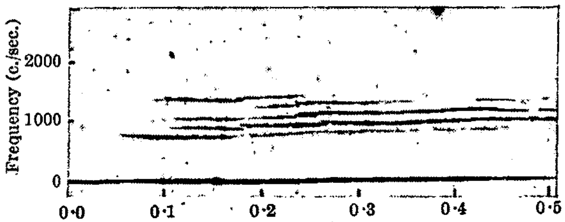

Fig. 1

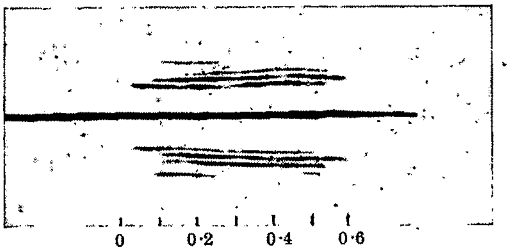

Fig. 2

The zero-frequency line in the record is produced by the steady component of the light transmitted by the sound film. Neglecting small phase-difference effects, the oscillograph pattern is symmetrical about this line, so that if the whole pattern is photographed, the effect is as shown in Fig. 2, which is derived from the same initial film record as Fig. 1. Also, Fig. 2 illustrates the effect of using a smaller velocity for the film B in transcribing, so that the time-scale is more compressed. The changes in the vocal resonance regions, also the swing of the harmonic frequencies away from the axis, due to rising pitch inflexion, are now more easily appreciated by the eye.

It is not proposed to discuss here possible applications of this method of presenting vibration phenomena, which, of course, need not be limited to acoustic vibrations. In the field of communications, reference may be made to the recent survey by Gabor[4]. Also, while the present work was in progress, a series of articles has appeared[5] describing some remarkable recent developments in the Bell Telephone Laboratories, and their applications. The sound-spectrograph there described achieves in a striking manner the result aimed at in our own investigations, a fuller account of which will be published elsewhere. In conclusion, we wish to acknowledge great assistance from Mr. C. F. Coleman in the conduct of these experiments.

Influence of Water on the Lubrication of Metals

EARLIER work[1] has shown that the simple physical adsorption theory of boundary lubrication is inadequate; fatty acids are not really effective in lubricating metals unless they are able to react chemically with the surface to form the metallic soap. Gregory's measurements have shown, for example, that platinum is not effectively lubricated by a dilute solution of a fatty acid, whereas cadmium is lubricated up to the temperature at which the appropriate cadmium soap softens. Using a variety of metals he found a general relation between lubrication and chemical attack of the metal. With many metals, the chemical reaction of the fatty acid to form the soap occurs via the surface oxide film or in the presence of oxygen[2]. If this view is correct, we should expect that fatty acids would not prove effective lubricants even on metals such as iron or cadmium if oxygen is excluded.

Experiments were carried out on the lubrication of metal surfaces which were freed from oxide and surface films by cutting a fresh surface under the applied lubricant. The Bowden–Leben[3] friction apparatus was used throughout. By means of a specially designed cutting tool, a smooth shallow track was laid bare on the lower metal surface immediately before its passage under the loaded hemispherical slider used to measure the force of friction. The results show at once that a 1 per cent. solution of lauric acid in paraffin oil is no more effective in lubricating the freshly cut metal surface than the paraffin oil itself. Further, if the lubricant is left on the surface for several hours, the lubrication remains poor, and this is true even if the temperature is raised to 100° C.

In other experiments, newly cut tracks were exposed to air for varying periods up to 24 hours; attempts were then made to lubricate them with the fatty acid solution. In the case of copper, lubrication was still ineffective even after 24 hours exposure. Magnesium and cadmium showed the same effect although to a lesser degree. In all cases, however, if the newly cut track was made wet with distilled water and allowed to dry before application of the lubricant, or was exposed to an atmosphere saturated with water vapour, good lubrication was immediately obtained. For effective lubrication, it is apparently necessary for *water* to have been present as well as oxygen.

In a series of corroborative experiments, the metal surfaces were abraded on emery paper under carefully dried benzene and kerosene, the lubricant being applied without allowing contact with the atmosphere. Here, again, the fatty acid solution was unable to provide good lubrication. Exposure of surfaces prepared in this way to distilled water in air caused lubrication to be effective.

Copper surfaces prepared in the normal way by abrading on emery paper under a stream of water are readily lubricated. A surface prepared in this way was heated to 200° C. and maintained at this temperature until an oxide film thick enough to give interference colours was formed. The specimen was then cooled in a vacuum desiccator to room temperature and treated with fatty acid solution. No lubrication was obtained. On covering an identically prepared oxide layer with a film of distilled water for one minute and then drying, the same fatty acid solution gave a low coefficient of friction.

Treatment of surface	Lubricant	Coefficient of friction (μ)		
		Copper	Cadmium	Magnesium
Abraded on emery under water.	1% lauric acid in paraffin oil	0·08	0·05	0·08–0·11
"	Paraffin oil	0·55*		
Oxide film removed by scraping under lubricant	1% lauric acid in paraffin oil	0·9–1·4*	0·35–0·45*	0·40*
"	Paraffin oil	0·75–1·15*	0·50*	
Abraded on emery under dry kerosene	1% lauric acid in paraffin oil	1·20*	0·30*	0·44–0·48*
"	Paraffin oil	>1*		0·46–0·50*
Thick dry oxide film formed by heating	1% lauric acid in paraffin oil	0·8–1·0*		
Ditto, exposed to water and dried	1% lauric acid in paraffin oil	0·08		

In all cases, the load on the slider was 4 kgm. and the speed of the lower surface 0·01 cm./sec.; * denotes irregular or intermittent motion.

The main results are summarized in the table.

The results provide additional evidence for the view that chemical reaction, with the formation of a soap film, is necessary for the effective lubrication of metal surfaces by fatty acids. The second conclusion of theoretical and practical interest is that water may play an essential part in this chemical reaction.

The role of water has a number of possible explanations. It may be that it leads to the formation of a loose hydroxide or hydrated oxide layer of a character suitable for penetration and reaction by the acid. Alternatively, water may facilitate a local ionization of the acid molecules at the seat of reaction.

I wish to express my thanks to Dr. F. P. Bowden and Dr. D. Tabor for helpful discussions.

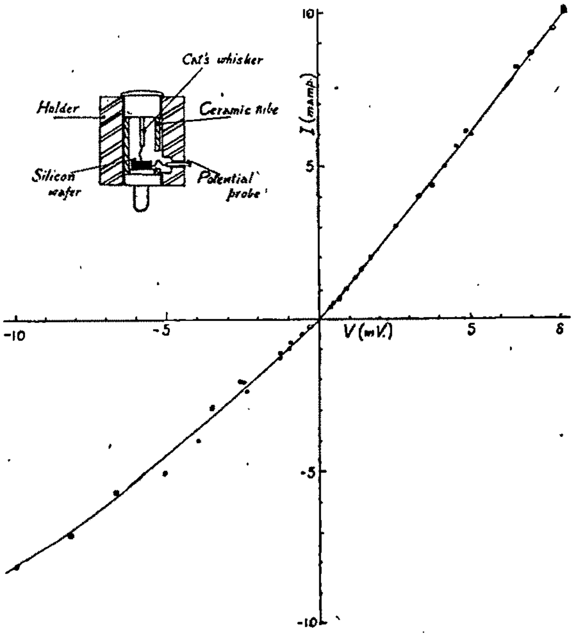
A Silicon-Metal Contact Resistance

THE rectifying action of a silicon crystal valve is a property of the contact between the silicon and a metal 'cat's-whisker'. In order to complete the circuit it is necessary to have a second silicon–metal contact the resistance of which must be small compared with that of the rectifying contact, so that the rectifying action is not cancelled out by the second contact.

It is usually assumed that the resistance of this second contact is negligibly small. During some recent measurements of silicon–metal contact resistances, an attempt was made to measure the value of this resistance in a commercial rectifier. The results showed that the resistance was small and could be neglected for most practical purposes, but it was large enough to introduce an error in determination of the crystal 'spreading resistance'[1] from the overall characteristics.

The crystal used was a *C V* 253 the performance of which lay within the normal spread. This type was chosen because its mechanical construction was convenient for the measurement. In this crystal a piece of silicon about 2 mm. square and 0·5 mm. thick is soldered to a brass pin which is fixed in one end of a ceramic tube. A brass cap is fixed in the other end of the tube. The cat's-whisker is fixed in the brass cap and presses on the surface of the silicon to make the rectifying contact. A hole was cut in the ceramic tube opposite the silicon, and a second cat's-whisker was inserted through this hole to make contact with the side of the silicon wafer. For mechanical stability the crystal and the second cat's-whisker were fixed in an insulating holder. The second cat's-whisker was used as a potential probe so that by taking a potential lead from the crystal-pin the resistance of the 'good' contact could be measured with a potentiometer.



The results are shown in the graph. This is a current-voltage characteristic for the 'good' contact and is the mean of three sets of readings taken over an interval of about a fortnight. The graph shows that the contact has a resistance of about 1 ohm and is slightly smaller when the current flows from pin to silicon across the contact than when the current flows in the reverse direction. This direction of low resistance is the reverse of that for the rectifying contact of the crystal. It does not seem that this resistance could be attributed to the silicon itself because the resistivity of the silicon will be about 0·1 ohm-cm., so that the piece in the crystal should have a resistance of less than 0·1 ohm.

While the 'good'-contact resistance is small, it is not negligible compared with the 'spreading' resistance, which for silicon crystal valves is usually in the region of 20–50 ohms. To check this conclusion, the forward characteristic of the crystal was measured in the usual way, and then measured using the second cat's-whisker as a probe in the same way that the 'good'-contact resistance was found.

The spreading resistance was estimated by putting $R_s \doteqdot \delta V/\delta I$, where δI is the change in current produced by a change in voltage δV when a large current I is flowing through the crystal. The results found for the crystal used were: from overall characteristic $R_s = 59 \cdot 5$ ohms, using cat's-whisker probe $R_s = 58 \cdot 5$ ohms. These results agree with the measurements of the 'good'-contact resistance.

One cannot expect to draw more than very general conclusions from a single measurement of this sort. It does seem worth pointing out, however, that an effect exists which is not completely negligible and is, in fact, large enough to affect accurate measurements of the spreading resistance, which are sometimes necessary in studying the performance of rectifiers. It is possible that this effect might cause more serious errors in germanium rectifiers, where the spreading resistance may be so low as 1–2 ohms.

While it is reasonable to expect the contact resistance for germanium also to be reduced in the same proportion, it would seem desirable to check this in view of the conflicting results obtained with germanium crystals.

I wish to acknowledge the financial assistance given by the Department of Scientific and Industrial Research which made the work possible.

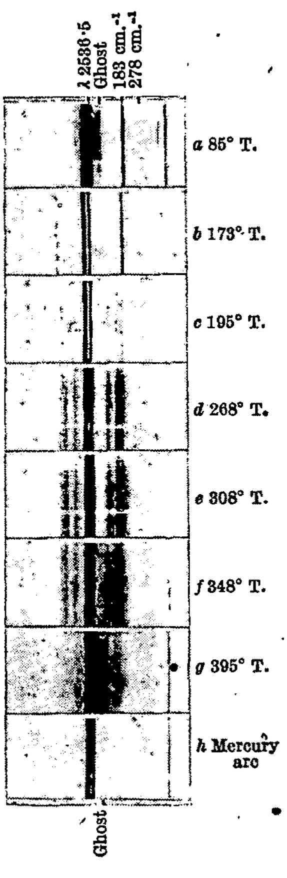
Vibration Spectra of the Alkali Halides

As is well known, ammonium chloride crystallizes in the cubic system, its structure being of the rock-salt type above 450° T. and of the cæsium chloride type below that temperature. Menzies and Mills[1] found that at liquid air temperatures it shows in its Raman spectrum a strong line with a frequency shift of 183 cm.$^{-1}$. This observation is significant, since the frequency shift corresponds to the *Reststrahlen* frequency of the crystal[2] and hence indicates that the oscillation of the NH_4 groups against the Cl ions is Raman-active. The crystal powder technique employed by Menzies and Mills is, however, not well suited for the study of Raman spectra in the region of such small frequency shifts. Accordingly, a fresh investigation has been made with a well-grown single crystal and the λ 2536·5 excitation and the same technique as in my recent investigations with various other crystals. To enable the entire sequence of changes to be observed, spectra were recorded with the crystal held at a series of seven temperatures down to that of liquid air.



The series of spectra reproduced, while confirming Menzies and Mills' results for the liquid air temperature, reveals numerous other interesting facts. The spectrum becomes diffuse and faint when the crystal is heated up above room temperature. *Per contra*, when the crystal is cooled down, the spectrum brightens and also sharpens remarkably, exhibiting even above the so-called λ-point transition (243° T.), a group of three fairly well-defined Raman shifts of 92, 141 and 170 $cm.^{-1}$ respectively, with indications of two fainter ones at 107 and 195 $cm.^{-1}$. These persist far below the λ-point transition, becoming at the same time quite sharp and showing a progressive shift in their position with falling temperature. A remarkable change in their relative intensities also occurs at the same time. At liquid air temperatures, a new line with a frequency shift of 278 $cm.^{-1}$ unmistakably makes its appearance. This is quite sharp but faint.

There can be little doubt that the features seen in the spectra reproduced arise from oscillations of the lattice in which the NH_4 groups may be considered to move as single units and that, with the exception of the 278 $cm.^{-1}$ line, they represent the first-order vibration frequencies of the lattice. The observed discrete character of the spectrum and the sharpening of the lines with falling temperature are both in accord with the fundamental ideas regarding the vibration spectra of crystal lattices put forward by Sir C. V. Raman[3] and are, therefore, experimental evidence of his theory. That the vibration frequencies in this case are Raman-active in the first order, instead of being inactive as in the metallic halides, is evidently a consequence of the NH_4 group possessing only tetrahedral symmetry as compared with the octahedral symmetry of the metallic ions.

Electron Microscope Investigation of the Action of Salt Solutions on Myosin

IN previous work it was shown that the thiocyanate anion (0·05 mol. solution of sodium thiocyanate), which produces monsters with large notochord and hyper-evocation in Amphibia embryos[1], also induces a decrease in viscosity of solutions containing euglobulin *b*[2]. On the other hand, lithium chloride induces an increase in viscosity of these solutions, at a concentration (0·14 mol.) which produces monsters with reduced notochord and hypo-evocation. A similar effect has been found for the viscosity of solutions containing fibrillar particles (myosin, sodium thymonucleinate)[3]. In order to find what kinds of modifications were induced by the various salts in the myosin solutions, an investigation with the electron microscope was undertaken.

Rabbit myosin, prepared according to the methods previously used, was dissolved in a 1-mol. solution of potassium chloride, to which was added: (*a*) nothing; (*b*) sufficient of a 1-mol. solution of potassium thiocyanate (or iodide) to bring the concentration of thiocyanate (or iodide) to 0·5 mol.; (*c*) sufficient of a 1-mol. solution of lithium chloride to bring the concentration of lithium salt to 0·14 mol. After twelve hours at 0° C., these solutions were examined by means of the electron microscope, on preparations fixed and stained for one minute with 0·1 per cent phospho-tungstic acid, according to the method of Hall, Jakus and Schmitt[4].

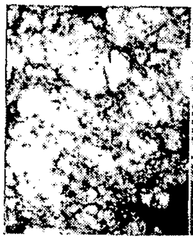

Fig. 1

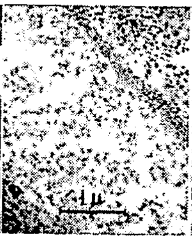

Fig. 2

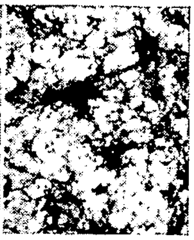

Fig. 3

Preparations of myosin dissolved in potassium chloride alone (*a*) show clearly a fibrillar structure (Fig. 1); those treated according to (*b*) show the loss, sometimes even total, of the fibrillar structure (Fig. 2); those treated according to (*c*) show clearly a fibrillar structure. This is in full agreement with the finding of a lower viscosity of the myosin solutions after addition of potassium thiocyanate (or iodide)[3], and of loss of flow birefringence in myosin solutions when treated with these salts[5]. It is also in agreement with the finding of a higher viscosity of myosin solutions by addition of lithium chloride (up to a final concentration of 0·25 mol.[3]) and of flow birefringence of myosin solutions in lithium chloride[5].

It is difficult, now, to establish the relations between our findings and those of Jakus and Hall[6] on solutions of Szent-Györgyi's water-soluble myosin. The filaments of this myosin, by increase of the concentration of potassium chloride in the solvent, are transformed into a granular background and, if the salt concentration is then lowered, the myosin re-aggregates: our myosin is Weber and Edsall's myosin, that is, distinct from water-soluble myosin.

The present researches show that the effect of the thiocyanate anion on a fibrillar protein such as myosin, as shown by the electron microscope, is quite different from that of lithium chloride, in agreement with what could be expected from our viscosimetric researches[2,3].

I am grateful to Prof. D. Marotta, general director of the Istituto Superiore di Sanità, Prof. G. C. Trabacchi, director of the Physics Department, who supervised the work done with the electron microscope, which was constructed by him, and to Prof. D. Bocciarelli, who took the photographs.

Plasma-Electron Oscillations

During the past ten years, a series of investigations on the generation of high-frequency oscillations in thermionic tubes containing gas at low pressure has been made in this laboratory. The vacuum electromagnetic wave-lengths involved, usually well below 100 cm., and the conditions under which they appear, are in the main consistent with the view that they are plasma-electron oscillations with frequency approximately equal to $10^4 n^{1/2}$ (n is electron concentration), originating near the cathode[1,2]. The shortest wave-length which can be obtained is, however, not about 15 cm., as indicated by previous publications, but 5 cm. or less. Whatever its exact value, this is likely to be determined by the damping of the oscillatory motion of the electrons by collisions with ions when the ionization is very dense, or by collisions between electrons and gas-molecules at the gas-pressures necessary to produce high electron concentrations readily.

The amplitude and wave-length of the oscillations which can be transmitted to an external circuit depend markedly on position on the current-voltage characteristic of the generating tube. With an oxide-coated cathode, oscillations can usually be detected over wide sections of the characteristic. With a bare filament cathode, the oscillation regions are much more restricted. Often there will be one oscillation region in the infra-saturation section, one at about the saturation 'knee', and a third in the saturation section some volts above the 'knee'. No tube which has been studied containing gas at less than 0·01 mm. mercury pressure failed to generate oscillations over some part of its characteristic curve.

The amplitude of the oscillations which can be detected by an internal probe depends considerably on the position of the probe, but the wave-length of the oscillations does not usually change much as the probe is moved. A number of amplitude-distance patterns like those reported by Merrill and Webb[3] have been obtained; these, taken in conjunction with the fact that on a number of occasions when a discrete beam of primary electrons could be observed, oscillations could be picked up by the probe only when the beam struck the probe, provide evidence that at least one of the processes operative is velocity modulation of the primary beam in a comparatively small volume of oscillating plasma. From the variation of frequency along the saturation part of the characteristic, it seems that the position of the oscillating volume near the cathode is not constant. There is also evidence that two volumes of plasma with different electron concentrations may oscillate simultaneously and independently, from the fact that a probe will occasionally pick up different frequencies in different parts of a tube[4]. This is in agreement with the theory of plasma electron oscillations, according to which the group velocity of the oscillations is almost zero[2].

The amplitude of the oscillations which can be obtained externally depends a great deal on electrode geometry, and upon the electrode to which the external circuit is connected. Thus with a simple coaxial electrode system with open ends, by far the strongest oscillations can be set up in a coaxial resonator if the central rod of the latter is joined end-on to the negative end of the filament, and if the filament is held taut and projects a little beyond the end of the anode. There is evidence that effects of this kind are connected in some cases with the movement of the electrons in the magnetic field of the filament-heating current, as the response of the resonator is reduced greatly by eliminating this. Further evidence for the existence of magnetic control is that an asymmetrical tube which normally gives feeble oscillations can be caused to give strong oscillations by bringing a bar magnet near it.

The way in which the plasma-electron oscillations are maintained is still not clear. One obvious possibility is that this is due to interaction between the primary electron beam and the plasma electrons, which depends on their relative speed, but the effects of magnetic fields suggest that some process which occurs with magnetrons may also come into play. It is also possible to draw an analogy between gas-filled diodes and 'hard' triodes giving Barkhausen – Kurz oscillations, with a potential maximum in the plasma of the gas taking the part of a positive grid in a 'hard' tube; it is, in fact, known from optical observations and probe measurements in some gas-filled diodes that a region of plasma with unusual properties extends outside the space-charge sheath on the filament for several times the diameter of the latter. Another possibility, suggested by Prof. K. G. Emeléus, is that plasma-electron oscillations outside the filament space-charge sheath are coupled with oscillations inside the sheath in which the potential minimum near the cathode forms and disappears discontinuously. With the complex conditions existing inside even the tubes of simple construction which have been studied, it would not be surprising if more than one of these effects, or others not considered here, should have to be taken into account ultimately.

The work described above has been carried out on behalf of the Director of Physical Research, Admiralty, and I wish to express my thanks to the Admiralty for permission to communicate these results.

Angle of Incidence of the Sun's Rays

The radiant heat from the sun received by each square foot of ground affects a number of questions, such as evaporation from the soil, the growth of close-growing crops, and snow conditions. One of the factors involved is (the sine of) the angle of incidence of the sun's rays; and calculation of this angle, according to aspect and inclination of hillside, and sun's bearing and altitude, may necessitate the solution of many spherical triangles; so the following short cut may be worth noting.

The angle of incidence on a slope at S is equal to the angle of incidence on the parallel plane touching the earth at T, the nearer of the two possible tangent points. As this parallel plane corresponds to the level surface at T, the sun's altitude at T is the angle required; and if the position of T can be found, that angle can be read directly from altitude (-azimuth) tables, without worrying about spherical triangles, or even azimuth.

But the problem is to find T. It lies on the great circle through S, the course of which at S corresponds

ANGLE OF INCIDENCE OF SUN'S RAYS

Slope		0°	10°	20°	30°	40°	50°	60°	70°	80°	90°	= Aspect
40° N.	Lat.	86	81·5	76	70	63·5	57	51	45	39	33·5	
	d Long.	0	3·65	4·35	4·55	4·5	4·3	4·1	3·85	3·65	3·35	
40° S.	Lat.	6	7	8	10	12·5	15·5	19	23	28	33·5	
	d Long.	0	0·4	0·85	1·25	1·65	2·05	2·45	2·75	3·0	3·35	

Lat. in degrees and decimals. *d* Long. in hours and decimals. Aspect is measured from N–S line. If it is easterly, *d* long. is plus; if westerly, minus.

to the aspect of the slope; and its angular distance from *S* is equal to the inclination of the slope. This great circle, and the latitude of *T*, and its *d* long. from the meridian of *S*, can be deduced from Towson's "Tables for Great Circle Sailing", which embody the solution of appropriate spherical triangles—if what Towson calls 'course' is interpreted as aspect, and what he calls 'distance' is interpreted as inclination. As the great circles are symmetrical about the meridian of *S*, the same values will serve for easterly and westerly aspects, provided that the correct signs are used when calculating hour angles.

Once the positions of *T*, according to aspect and inclination of slope, have been tabulated for a given latitude of *S*, the resulting figures can be used for any time of year, and any hour of day. Further, the times at which the slope at *S* gets and loses the sun, if it does so after sunrise or before sunset, will be simultaneous with sunrise and sunset at *T*.

To give an example, the accompanying figures from the table for lat. 46° N. will apply to the Alps, as they lie between 45° and 47° N.

Random Association of Points on a Lattice

MORAN[1] has given the first and the second moments for the probability distribution of 'black – white' joins when *mn* points black or white with probabilities p and $q = 1 - p$ respectively are distributed on a lattice of *m* rows and *n* columns. During the course of a detailed study of similar problems, I have worked out the first and the second moments for the distribution of the total number of joins between points of different colours when the lattice consists of points of *k* colours with probabilities $p_1, p_2 \ldots p_k$, such that $\sum_1^k p_r = 1$. These results for one, two and three dimensions are given below:

(1) One-dimensional lattice: *m* points on a line:

$$\mu_1^1 = 2(m-1)\,\Sigma p_r p_s$$
$$\mu_2 = 2(2m-3)\,\Sigma p_r p_s + 2(14-9m)\,\Sigma p_r p_s p_t + 4(5-3m)\,\Sigma p_r^2 p_s^2 + 8(3m-5)\,\Sigma p_r p_s p_t p_u$$

(2) Two-dimensional lattice: $m \times n$ points:

$$\mu_1^1 = 2(2mn-y)\,\Sigma p_r p_s$$
$$\mu_2 = 2(8mn-7y+4)\,\Sigma p_r p_s - 4(19mn-17y+10)\,\Sigma p_r p_s p_t - 4(14mn-13y+8)\,\Sigma p_r^2 p_s^2 + 8(14mn-13y+8)\,\Sigma p_r p_s p_t p_u$$

(3) Three-dimensional lattice: $l \times m \times n$ points:

$$\mu_1^1 = 2(3lmn-x')\,\Sigma p_r p_s$$
$$\mu_2 = 2(18lmn-11x'+4y')\,\Sigma p_r p_s - 2(87lmn-54x'+20y')\,\Sigma p_r p_s p_t - 4(33lmn-21x'+8y')\,\Sigma p_r^2 p_s^2 + 8(33lmn-21x'+8y')\,\Sigma p_r p_s p_t p_u,$$

where $y = m+n$, $x' = lm+mn+nl$, $y' = l+m+n$. The summations are taken for all values of *r*, *s*, *t* and *u* different from one another. The joins considered are those along mutually perpendicular axes.

It can be shown that the distributions tend to the normal form when *m*, *mn* and *lmn* are increased.

The corresponding results when the lattices consist of $n_1, n_2 \ldots n_k$ fixed numbers of points from the different colours have also been worked out. These results, being more complicated, will be given in a detailed communication to be published shortly.

Micro-Estimation of Sugars Separated on the Filter Paper Chromatogram

IN view of the recent communication from Flood, Hirst and Jones[1] on this subject, a description of a method developed in this laboratory may be of interest. The same principle is used for the separation of sugars in a mixture, but a different method of extracting the separated sugars from the paper is employed, and the final estimation is carried out by a micro method free from the disadvantages associated with the Somogyi method and gives directly the weight of the sugar without the use of a reference compound. Certain of the established microchemical techniques developed in the Carlsberg Laboratory[2] are employed, and the scale of the method is correspondingly reduced. The procedure is, briefly, as follows.

By means of an accurately calibrated micro-pipette, replicate spots of known volume (4·05 µl. throughout these experiments) of the solution of sugars are placed at intervals of 3 cm. on the starting line of a filter-paper chromatogram, and the separation of the sugars is carried out as described by Partridge[3], care being taken to ensure that the solvent front remains straight and at right angles to the edge of the paper. The bulk of the solvent is then removed from the chromatogram *in vacuo*, a strip (on which will lie one complete set of the separated sugar spots) is cut from the paper and the position of these spots is revealed by development with ammoniacal silver nitrate.

Using this reference strip as a guide, the main portion of the chromatogram is then cut so that the individual sugar spots lie on pieces of paper approximately 3 cm. × 7·5 cm. long which are trimmed to a point, the sugar spot lying about 1 cm. from the tip. The subsequent treatments are also applied to blank pieces of the same size.

The pieces containing the sugars are freed from the chromatographic solvent by extraction in a Soxhlet condenser with anhydrous ether (petroleum ether, b.p. 60–80°, if xylose is present). The individual sugars are then washed off the pieces by a procedure analogous to the chromatographic separation, but using distilled water in place of the chromatographic solvent. The dilute sugar solutions are collected in micro-pipettes, the tips of which rest against the points of the filter paper strips. (This method of extraction was suggested by Dr. A. J. P. Martin.) The solutions are transferred from the pipettes to cups cut in a block of paraffin wax, a total of 0·3–0·4 ml. of solution being collected from each paper. The solutions are then evaporated to dryness over phosphorus pentoxide.

To the paraffin cup 17 µl. of bicarbonate buffer pH 10·6 is added from a micro-pipette and the sugar dissolved with the aid of a fine, ball-tipped glass needle. The drop of sugar solution is then transferred by means of the same pipette to a waxed reaction tube[4]. Two further portions, each of 17 µl., of buffer are used to rinse the paraffin cup, the needle and the pipette, and are transferred in turn to the main solution in the reaction tube.

The estimation of the sugar is then carried out by the micro modification of the Willstätter and Schüdel method (stoichiometric oxidation by hypoiodite and titration of the excess iodine with thiosulphate) developed by Linderstrøm-Lang and Holter[4], oxidation being allowed to proceed for 45 minutes at 24° C.

Typical results obtained with a number of sugars using butanol-acetic acid-water[3] as the chromatographic solvent are given in the accompanying table, the figures quoted being the averages of four to six results from replicate spots run on the same paper.

Expt.	Sugars in mixture	R_F[3]	Taken (µgm.)	Found (µgm.)	Error %
1	Glucose	0·18	44	46	+ 4·5
	Lactose	0·09	76	76	0
2	Glucose	0·18	57	59	+ 3·5
	Lactose	0·09	107	105	− 2
3	Galactose	0·16	81	73	−10
	Maltose	0·11	94	91	− 3
4	Mannose	0·20	42	40	− 5
	Xylose	0·28	42	40	− 5

In its present form the method is capable of separating and estimating with an accuracy of about ± 5 per cent as little as 40 µgm. of a sugar, though the error of a single estimation is about twice as great. The Linderstrøm-Lang and Holter method of estimating sugars, however, is capable of estimating quantities of the order of 10 µgm. with a high degree of accuracy, and the present technique should be capable of refinement to allow of the separation and estimation of quantities of sugars of this order.

Hydrolysis of Bi^{3+}. Oxygen Bridging—a New Type of Ionic Equilibrium

It is well known that the ion Bi^{3+} easily reacts with water (is hydrolysed) so that hydrogen ions are set free. Very little is known, however, of the nature of the reaction products. In 1936 Holmqvist[2], and Prytz and Nagel[4] working independently, concluded that there are certainly not only mononuclear complexes ($BiOH^{2+}$, BiO^+) but also polynuclear complexes containing more than one bismuth atom. Holmqvist even tried to apply the law of mass action assuming definite formulæ, namely, $Bi_2(OH)_4^{2+}$ and $Bi_2(OH)_5^{+}$.

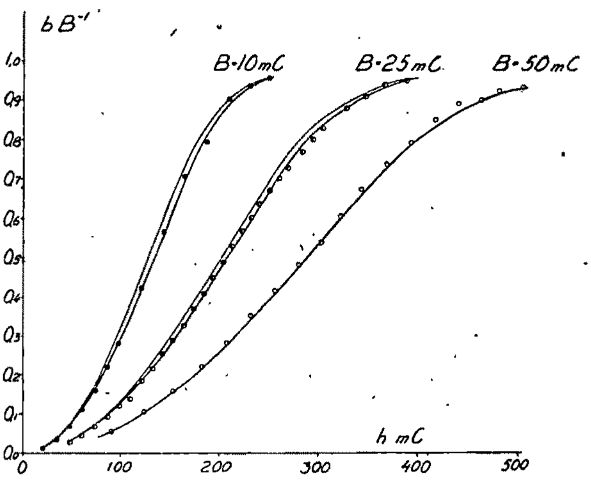

Fig. 1. $bB^{-1} = (Bi^{3+})_{free}/(Bi)_{total}$ AS A FUNCTION OF $h = (H^+)$. Circles = experimental values. The thick line for B = 50 millimol. and the thin lines for B = 25 and B = 10 millimol. are calculated with the constants $k_1 = 0·065$ and $k = 2·80$ mol. per litre. The thick lines for B = 25 and B = 10 millimol. are calculated with the best constants obtainable in each case: k_1 = 0·070 mol. per litre, k = 2·95 mol. per litre and k_1 = 0·060 mol. per litre, k = 3·15 mol. per litre

We have tried to measure accurately by E.M.F. methods the concentrations of free Bi^{3+} and H^+ in a series of solutions containing $Bi(ClO_4)_3$ or $BiOClO_4$, $HClO_4$ and $NaClO_4$ in such proportions that (ClO_4^-) is always equal to 3 mol. per litre.

Our results cannot be explained by assuming that only mononuclear complexes are formed, nor by assuming only one or two different polynuclear complexes. However, they agree surprisingly well with those calculated by assuming a simple mechanism ('oxygen bridging'):

$$Bi^{3+} + H_2O + Bi^{3+} = Bi_2O^{4+} + 2H^+ \qquad (1)$$

$$Bi_2O^{4+} + H_2O + Bi^{3+} = Bi_3O_2^{5+} + 2H^+ \qquad (2)$$

$$Bi_3O_2^{5+} + H_2O + Bi^{3+} = Bi_4O_3^{6+} + 2H^+ \qquad (3)$$

$$Bi_nO_{n-1}^{(n+2)+} + H_2O + Bi^{3+} = Bi_{n+1}O_n^{(n+3)+} + 2H^+ \qquad (n)$$

We assumed that the equilibrium constants of all these reactions are equal to k, except the first one which is called k_1. Fig. 1 shows the fraction $\frac{(Bi^{3+})\text{ free}}{(Bi)\text{ total}}$ as a function of (H^+); the experimental points are in good agreement with the curves obtained by assuming k_1 = 0·065 molar and k = 2·80 molar.

The fact that k_1 is so much smaller than k can be explained if the higher complexes from $Bi_3O_2^{5+}$ onwards tend to form closed complexes such as

Bi—O—Bi
| |
Bi—O

which should be favoured by electrostatic attraction. In this way larger complexes can be formed, such as:

Bi—O—Bi—O—Bi
| | | | |
O—Bi—O—Bi—O
| | | | |
Bi—O—Bi—O—Bi

These can be regarded as crystallization nuclei of the tetragonal $(MeO)_n$ sheets found in the crystal structures of many bismuth oxyhalides[1,5] and also in bismuth oxycarbonate[3] (Fig. 2).

It is not claimed, of course, that our picture of the reaction is exact. For example, the assumption of a common k is rather crude, and we have neglected the aquo acidity (which may become important at lower

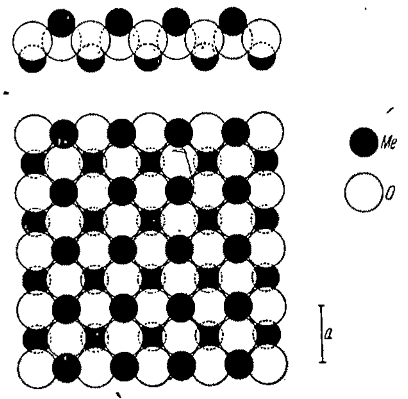

Fig. 2. TETRAGONAL METAL – OXYGEN SHEET IN BISMUTH OXYHALIDES, VIEWED ALONG *a* AND *c* AXES

(H^+) than those studied by us), and the possibility of rings of formula $(BiO)_n^{n+}$, such as  or  It is hoped, however, that our description records the essential features of the Bi^{3+} hydrolysis.

It seems possible that a similar mechanism (in some cases perhaps with OH bridges) occurs also in the hydrolysis of other ions, such as Sb^{3+}, Pb^{2+}, UO_2^{2+}, and may be Fe^{3+}.

A detailed paper on this work will be submitted to *Acta Chemica Scandinavica*.

The Electron Affinity of ClO

IN a recent paper, Weiss[1] has given an estimate of the electron affinity of the ClO molecule, by a method which makes use of existing thermochemical data on the chlorine oxides and oxyacids. A necessary datum in the scheme of Weiss is the dissociation-energy of ClO, for which he chooses a value of 30·4 kcal. mol.$^{-1}$, quoting an early paper of Goodeve and Wallace[2]. Weiss appears to have overlooked a more recent publication by Goodeve and Marsh[3], in which the authors deduce that the ClO dissociation-energy is about 67 kcal. mol.$^{-1}$.

The latter figure is certainly more compatible with present views on the nature of the chemical binding in the ClO molecule. The resonance between the extreme structures:

$$:\underset{\cdot\cdot}{\overset{\cdot\cdot}{\mathrm{Cl}}}:\underset{\cdot\cdot}{\overset{\cdot\cdot}{\mathrm{O}}}: \qquad \text{and} \qquad :\underset{\cdot}{\overset{\cdot\cdot}{\mathrm{Cl}^+}}:\underset{\cdot\cdot}{\overset{\cdot\cdot}{\mathrm{O}^-}}:$$

(1) (2)

must result in a ground state of *greater* binding-energy than that of the normal electron-pair Cl—O bond. The normal Cl—O bond has an energy value lying approximately midway between the Cl—Cl and O—O bond-energies. Although there is some doubt in regard to the value of the O—O bond-energy[4], there is little question that the correct value is not *less* than Pauling's estimate of 36 kcal.; accordingly, the covalent Cl—O bond-energy may be estimated at not less than 47 kcal. The bond-energy in the actual ClO molecule must therefore be in excess of 47 kcal., by an amount equal to the resonance-energy of the interaction between the structures (1) and (2).

If the value (67 kcal.) given by Goodeve and Marsh is accepted as the best at present available, it may be combined with the value for the heat of formation of HClO aq. (26 kcal.) to give:

$$S(\mathrm{H}^+) + S(\mathrm{ClO}^-) + E(\mathrm{ClO}) = 416{\cdot}3 \text{ kcal.}, \qquad (1)$$

where the S terms are heats of solution, and the E terms are electron affinities. A further equation,

$$S(\mathrm{H}^+) + S(\mathrm{OH}^-) + E(\mathrm{OH}) = 427{\cdot}8 \text{ kcal.}, \qquad (2)$$

may readily be obtained from a knowledge of the heat of electrolytic dissociation of water, and the energy of rupture of the first OH bond in $H_2O(g)$[5]. Combining equations (1) and (2), it follows that

$$S(\mathrm{O\bar{H}}) + E(\mathrm{OH}) = S(\mathrm{ClO}^-) + E(\mathrm{OCl}) + 11{\cdot}5 \text{ kcal.} \qquad (3)$$

The heat of solution of the $\mathrm{Cl\bar{O}}$ ion is a matter for speculation, but it must certainly be less than $S(\mathrm{O\bar{H}})$; as a crude approximation, one might assume $S(\mathrm{\bar{O}Cl}) \sim 3/4\ S(\mathrm{\bar{O}H})$, on the grounds that the chlorine atom in $\mathrm{O^-Cl}$ virtually blocks one of the four positions in which water molecules normally surround the O^- or $\mathrm{\bar{O}H}$ ion. With this simplification, equation (3) becomes

$$E(\mathrm{OCl}) \sim E(\mathrm{OH}) + 1/4S(\mathrm{\bar{O}H}) - 11{\cdot}5. \qquad (4)$$

Bernal and Fowler[6] have estimated $S(\mathrm{\bar{O}H})$ at 105 kcal., and quote 276 kcal. for the term $S(\mathrm{H}^+)$: substitution of these figures in equations (2) and (4) gives

$$E(\mathrm{OH}) \sim 47 \text{ kcal.}; \quad E(\mathrm{OCl}) \sim 61 \text{ kcal.}$$

These values may be justified by an argument which is independent of assumptions regarding the probable values of the solution heats of ions. Representing the dissociation energies of the two processes

$$\text{(i)}\quad \mathrm{ClO} \rightarrow \mathrm{Cl} + \mathrm{O} - D_1$$

$$\text{(ii)}\quad \mathrm{Cl\bar{O}} \rightarrow \mathrm{Cl} + \mathrm{O}^- - D_2$$

by D_1 and D_2, and the electron affinity of the oxygen atom by $E(\mathrm{O})$

$$\text{(iii)}\quad \mathrm{O} + e \rightarrow \mathrm{O}^- + E(\mathrm{O}),$$

the electron affinity of ClO may be written as:

$$E(\mathrm{OCl}) = E(\mathrm{O}) + D_2 - D_1. \qquad (5)$$

Whereas the value D_1 is larger than the covalent Cl—O bond-energy, for reasons already discussed, it is probable that the bond-energy D_2 is almost identical with the normal Cl—O bond-energy. Resonance in the $\mathrm{Cl\bar{O}}$ ion is restricted to that between the covalent-bond structure $:\underset{\cdot}{\overset{\cdot\cdot}{\mathrm{Cl}}}:\underset{\cdot\cdot}{\overset{\cdot\cdot}{\mathrm{O}^-}}:$, and the ionic structure $\overset{+}{\mathrm{Cl}}\ \overset{=}{\mathrm{O}}$, and good reasons can be given for the expectation that the ionic-covalent resonance energy in this case should be small. Hence, we would expect $D_1 > D_2$, and $E(\mathrm{OCl}) < E(\mathrm{O})$. Vier and Mayer[7] have recently measured $E(\mathrm{O})$ as 71 kcal.; we have pointed out that the value D_1 is greater than the normal Cl—O bond-energy by not more than 20 kcal. Thus, we would conclude that $E(\mathrm{OCl})$ must lie between the limits 51 and 71 kcal.

DR. SKINNER was good enough to send me a copy of his communication. More recently we have also been led to assume considerably lower values for the sum of electron affinity and heat of hydration of the ClO radical from a study of the photochemistry of hypochlorites in solution. This seems to suggest a value of $\{E(\mathrm{ClO}) + S(\mathrm{ClO}^-)\} \sim 105$ kcal.

I was, however, unaware of the ClO bond-energy value as given by Goodeve and Marsh to which Dr. Skinner has directed my attention.

Introducing this value into my previous calculations, the corresponding former figures should be diminished by the difference between the values of Goodeve and Marsh, and Goodeve and Wallace ($\sim$ 37 kcal.).

Thus one obtains $\{E(\mathrm{ClO}) + S(\mathrm{ClO}^-)\} \sim 128$ kcal. which, with the previously assumed value of $S(\mathrm{ClO}^-) \sim 60$ kcal., leads to $E(\mathrm{ClO}) \sim 68$ kcal.

Physiological Heterogeneity of Metaphosphate in Yeast

IT has been shown that when yeast is fractionated by repeated extractions with cold trichloracetic acid a species of phosphate, found in both the acid-soluble and the residue fractions, is identifiable as metaphosphate[1,2]. The co-existence in a yeast cell of metaphosphate in both acid-soluble and acid-insoluble forms suggests the possibility that these two may differ in their metabolic and physiological function. It is the purpose of the present note to report some recent observations which indicate that this is the case.

Resting cells (*S. cerevisiæ*, baking type, 48-hour culture) were incubated under anaerobic conditions while suspended in a medium containing 6 per cent glucose, phosphate buffer (*p*H 4·5) and P^{32} labelled inorganic phosphate. After 2 hours incubation at 30° C., these cells were extracted with 5 per cent trichloracetic acid for one and a half hours at 3° C. The resulting supernate (S_1) was treated according to the flow sheet, Fig. 1. In the precipitation with the magnesia mixture the test solutions were allowed to stand overnight in the cold. The precipitate denoted as P_3 contained a portion of the acid-soluble metaphosphate and exhibited no activity, showing that no exchange had taken place. The orthophosphate contained in the supernate (S_3) showed that exchange had occurred to the extent of 24 per cent (based on initial P^{32} content of the phosphate in the medium).

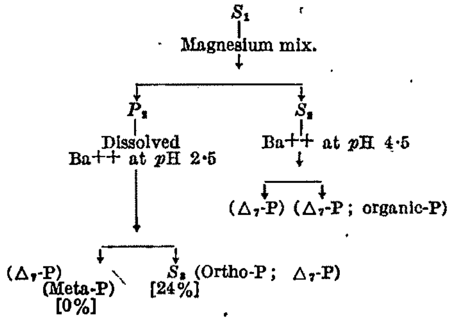

Fig. 1. Fractionation of the supernate from a cold trichloracetic acid extraction of yeast. The first step accomplishes a partial separation of metaphosphate by the use of a magnesia mixture which precipitates a mixture of meta- and orthophosphates. The metaphosphate can then be removed in a highly purified state by a precipitation with Ba++ at acid *p*H. As is indicated, the procedure does not remove all the metaphosphate from the original trichloracetic acid extract. Data in parentheses indicate type of phosphate compound found. Numbers in brackets give extent of equilibration with external phosphate in medium.

If the Schmidt[3] method of fractionation is carried out following the cold trichloracetic acid extraction, there is obtained a residue (R_5) which can be shown to contain a large amount of 7-min. hydrolysable phosphate (completely hydrolysed to orthophosphate by treatment for seven minutes with 1 N hydrochloric acid at 100° C.). If this is treated according to the flow sheet in Fig. 2, another metaphosphate fraction (P_8 of Fig. 2) can be isolated. This metaphosphate is a highly active fraction and has, as indicated, exchanged to the extent of 24 per cent. In fact, this is the only fraction thus far examined which approaches in activity that of the internal orthophosphate of the cell.

It appears, therefore, that there are at least two different kinds of metaphosphate in yeast, differing radically in metabolic function. One, which is easily extractable by trichloracetic acid in the cold, presumably does not exchange with any other phosphate fraction in the cell. The other, which is apparently associated with a proteinaceous material, is one of the most highly active organic phosphates in the cell. This result is reminiscent of work reported many years ago by MacFarlane[4].

Aside from possible implication for the physiology of the yeast cell, the results reported here concern the validity of conclusions derivable from isotope

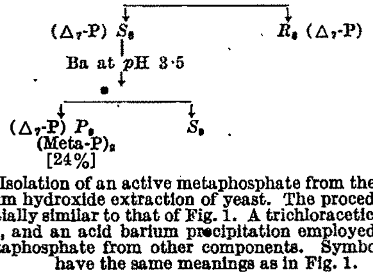

Fig. 2. Isolation of an active metaphosphate from the residue of a potassium hydroxide extraction of yeast. The procedure followed is essentially similar to that of Fig. 1. A trichloracetic acid extract is made, and an acid barium precipitation employed to separate the metaphosphate from other components. Symbols employed have the same meanings as in Fig. 1.

experiments. It is evident that the employment of chemical procedures which would recover all of the metaphosphate from the yeast cell as one fraction would mask the existence of physiologically different usages for the same chemical compound. Such a procedure could result in false conclusions with regard to the metabolic significance and function of such a compound.

Detailed accounts of the experiments described here will be published elsewhere. This work is being supported by a grant from the American Cancer Society.

Maintenance of Spermatozoal Motility in Dilute Suspension

The rapid immobilization of mammalian spermatozoa which occurs when an ejaculate is diluted with a large volume of physiological saline is the basis of Milovanov's[1] test of 'resistance', used in assessing the value of a specimen for artificial insemination. Milovanov attributes this immobilization to the toxic action of chloride ions. Chang[2] also remarks on the low motility, rate of respiration and fertilizing capacity of rabbit spermatozoa in dilute suspension. Our own observations confirm these findings; rabbit spermatozoa at a concentration of 20 million/ml. in Baker's[3] solution remain motile for two or three days at room temperature, whereas at a concentration of 0·4 million/ml. they are motionless within an hour or two. In our experience this rapid loss of motility is not attributable to a toxic action of chlorides, since chloride-free diluents have an identical action.

Dr. A. Walton had told us of an observation in his laboratory that an emulsion of liquid paraffin helps to maintain the motility of suspensions of spermatozoa. His suspensions were not, however, highly diluted. Emulsions of liquid paraffin with a little gum arabic added to assist emulsification in Baker's solution were therefore tried, and found to be highly effective in maintaining good motility for short periods of time (not more than 6–12 hours). However, it was then discovered that gum arabic alone, starch, glycogen, egg yolk, egg white, crystalline serum proteins and a number of other substances are equally effective. On the other hand, agar, gelatin, sodium silicate and catalase are entirely without effect. Supernatants from other suspensions of rabbit spermatozoa proved highly effective, and the sperm-free plasma from a vasectomized buck was also effective, but not as good as supernatants from whole semen, prepared from suspensions which had stood overnight.

Full details of these tests will be published elsewhere, but the following table is included to illustrate the striking results obtained. The motility of suspensions kept at room temperature is given a score of between 0 and 4, according to the activity of the spermatozoa[4].

SUBSTANCES EFFECTIVE IN MAINTAINING THE MOTILITY OF SUSPENSIONS OF RABBIT SPERMATOZOA IN BAKER'S SOLUTION AT 4 × 10^5 cells/ml.

Substance	Ejaculate	Motility score at hour					
		½	1½	2½	4	6	24
Controls at 2 × 10^7/ml.	1	4	4	4	4	4	3
	2	3	2	2	2	2	1½
Controls at 4 × 10^5/ml.	1	0	0	—	—	—	—
	2	1	¼	0	0	—	—
0·25% W/V starch	1	3½	3½	3	3½	2½	0
	2	2	2¼	2¼	1½	½	0
0·25% W/V glycogen	1	3½	3½	3½	4	2¼	0
	2	3	2	2¼	2	1¼	0
0·25% carbohydrate-free serum protein	1	3½	3½	3½	4	3	½
	2	3	2¼	2¼	2¼	2¼	¼
0·25% serum protein containing 7% carbohydrate	1	2½	3½	3½	3½	2½	0
	2	3	2	2	2	2	0

Two features of this table need comment. First, there was sometimes a small rise in motility during the test, attributable to a rise in room temperature. Secondly, there was little or no motility in any but the control suspensions at 20 million/ml. at 24 hours, which demonstrates that the action of the various effective substances is not long maintained.

The capacity of such widely differing materials to preserve motility in dilute suspension makes it highly probable that their action is physical and not chemical. Therefore, the possibility was explored that they adsorb a toxic agent present in the diluent. Baker's solution contains traces of copper, lead and arsenic, and these seemed the most likely agents. However, neither special purification of the diluent nor the addition of relatively large excess of these metals affected the spermatozoa in suspension at 20 million/ml., which, surprisingly enough, are unaffected for the first six hours by 160 parts per million of copper or lead, or 48 parts per million of arsenic. Only copper eventually reduced motility, at 24 hours, in comparison with the controls. We were thus inclined towards a second hypothesis, that the various effective substances in some way prevent the escape of essential material, perhaps an enzyme, from the sperm cells. This receives support from the observation that repeated washing in Baker's solution does not cause immotility in suspensions at 20 million/ml. at a stage when the concentration of seminal plasma is reduced to that equivalent to dilution to 0·4 million/ml., but does cause immotility when further washings are given (controls washed repeatedly in the original supernatant, rich in seminal plasma, remain motile).

It is therefore concluded that the immobilizing effect of high dilution is probably due to the loss of vital material from the spermatozoa. The mode of action of the various effective substances which prevent the phenomenon is unknown. It seems unlikely, but possible, that they all contain some common impurity (like biotin) which is responsible for their effectiveness, and if so, it might operate in some manner other than the prevention of loss of intracellular material.

Contribution of the Major Constituents to the Refractive Index of Milk

RECENT investigations[1,2] have shown the possibility of measuring the refraction in milk and the variations of the value under routine conditions of management.

A comparative examination of the refractive indices of more than 70 bi-weekly samples of milk and its rennet serum, prepared with one drop of Hansen's liquid rennet in 25 c.c. of milk, gave the following limits of variation of the constant. (In this proportion rennet caused no detectable addition to the refractive index of milk, as judged immediately after addition of rennet, and before coagulation set in.)

REFRACTIVE INDEX OF MILK AND MILK SERUM

Sample	Cow (R.I. 20° C.)	Buffalo (R.I. 20° C.)
Milk	1·3474–1·3506	1·3484–1·3534
Milk serum	433–447	436–453

These figures show not only that the elimination of casein reduces considerably the refractive index (fat having been shown to contribute nothing to this value[1]), but also that the variability of the constant of the serum is less than that of milk. Analysis of the entire data also showed that the refractive index of the serum does not always follow that of milk. This fact, and the lack of an exact linear relation between the refractive index and the solids-not-fat of milk[2], is perhaps caused by the differences in mutual proportions of the several constituents of milk. In other words, although two samples of milk (or of milk serum) may have the same solids-not-fat, the difference in the ratio of protein : lactose : minor constituents in the samples is responsible for the difference in refractive index.

Refractive index being a cumulative property, the presence of each solute adds to the refractive index of the water in milk. It has not been possible, so far, to determine the share of the several constituents in the total refraction, since there was no method of estimating the refractive index of milk. The method[1] recently devised enables such an estimation to be made.

A process of successive elimination of the major constituents and determination of the refractive index of the resulting fluids was used in determining the share of each. Casein (together with fat) was first eliminated with a drop of rennet. The lactalbumin and globulin in the rennet serum[3,4] was then removed by ultrafiltration with 'Cellophane' under a pressure of 20 kgm./cm.^{2}. The refractive index and composition (including lactose[5]) of the milk sample and filtrates were also estimated. The excess of the value of the refractive index of the ultrafiltrate over that of a solution containing the per cent lactose in the sample determined the share of the minor constituents (mineral salts, non-protein nitrogen, citric acid, etc.). From a number of samples of cow milk so examined the following conclusions have been drawn.

In the refractive index of milk, proteins contribute, next to water, the largest fraction, lactose ranks next and minor constituents the least. But *in proportion to their percentages*, water, proteins, minor constituents and sugar contribute in descending order. Among the proteins, considering their proportion, the lactalbumin and globulin contribute much more than casein. These experiments consistently gave a refraction of 0·0021 gm. casein in 100 c.c. of milk. This is slightly higher than the values given by Robertson[6] (0·00152) and Brereton and Sharp[7] (0·00181) for a 1 per cent solution of casein in 0·1 *N* sodium hydroxide. The higher value in the present series of experiments is perhaps to be attributed to difference in dispersion and composition in milk and in the sodium hydroxide solution.

The data also show that milk sugar contributes the most constant value to the refractive index, and confirms the inference from the table above that the wide changes in the refractive index of milk are accounted for largely by the variations in the protein content of milk.

Thanks are due to Mr. B. N. Banerjee and Prof. V. Subrahmanyan for their interest in these investigations.

Determination of Benzene Hexachloride in the Blood of Cattle

DE MEILLON[1] reported that various arthropods are killed when fed upon rabbits which had received 'Gammexane' by ingestion. Similarly, Dr. S. G. Wilson, of the Veterinary Research Laboratories, Entebbe, Uganda, has found that the blood of cattle which had received benzene hexachloride by oral ingestion was toxic to tsetse flies for a considerable time after treatment[2]. Although biological tests thus showed that the insecticide was circulating in the blood, it seemed useful to apply the normal methods for the analysis of benzene hexachloride to estimation of the concentration in the blood of treated animals.

The simplest estimation of this insecticide depends upon the removal of three atoms of chlorine from each molecule of any of the benzene hexachloride isomers by refluxing with ethanolic potassium hydroxide and afterwards titrating the chloride ions present in the solution.

Outline of the method: 10 ml. of fresh oxalated blood were ground with anhydrous sodium sulphate and extracted with benzene. After evaporation of the benzene, chloride formed by dehydrohalogenation of the residue was determined by one of two methods. Method 1 is the Volhard procedure as used by Neal *et al.*[3]. This was found to be too insensitive for the quantities normally recovered from blood, and Method 2 was substituted, in which the silver chloride was filtered off before titration with potassium thiocyanate solution. Recoveries of 'Gammexane' (the gamma isomer of benzene hexachloride), added to blood from untreated animals, were satisfactory, and the error does not appear to be greater than 2–3 per cent in the range of concentrations which have so far been found in cattle bloods. Details of the method will be published later.

Some results are given in Table 1.

One experiment has been performed in which a calf was sprayed with the insecticide in oil solution (an extract of crude benzene hexachloride with a mixture of equal parts by volume of power kerosene and cotton seed oil).

TABLE 1. BENZENE HEXACHLORIDE FOUND IN CATTLE BLOODS AFTER ORAL INGESTION

Animal	No. of doses (1 dose = 0·25 gm./kilo)	Days after ingestion	Mgm. found per 100 ml. blood	Method
5592	4*	7†	2·3	1
		14	1·7	1
		19	2·1	2
		29	2·1	2
5598	1	1	2·5	1
		2	1·5	1
		7	1·1	1
		14	0·4	2
5606	1	1	1·7	1
		2	1·5	2
		3	1·1	2

* On four successive days. † Counted from the last of these days.

Although this work is of a preliminary nature, it does appear that the insecticide persists in the blood for some time after oral ingestion, the actual duration depending upon the size of the initial dose. In addition, there is some variation between individual animals. The method used does not, of course, show that the substance determined is benzene hexachloride as administered, but in conjunction with the biological results it would appear that this is so.

TABLE 2. BENZENE HEXACHLORIDE IN BLOOD AFTER SPRAYING THE SKIN

	Days after spraying							
	0*	1	2	3	4	5	6	7
Deposit on hide, mgm./sq. ft.	0	41	8	14	10	0	0	0
Concentration in blood, mgm./100 ml.	0	0	0·3	2·5	2·2	0·2	0	0

* Just prior to spraying.

By the spraying experiment, it is indicated that at least one cause of the loss of effectiveness of insecticides applied in oil solution to cattle is absorption of the oil through the skin. Thereafter the compound circulates for several days in the blood, as was found after oral ingestion.

I am indebted to Dr. Wilson for the use of some of his experimental animals in these determinations.

'DD' as a Means of Controlling *Heterodera rostochiensis* (Woll.)

INVESTIGATIONS during the past four years into the chemical control of *H. rostochiensis* have revealed that chloropicrin, ethylene dibromide, 'Dowfume G', 1–2 dichloropropene and 1–3 dichloropropane (crude 'DD') and two high boiling-point fractions of crude 'DD' are all effective soil fumigants. Because of its efficacy, ease in handling and comparative low cost, crude 'DD' is outstanding among these.

Concentrations up to 75 gallons of 'DD' per acre have been used with varying degrees of success. Soils ranging from almost pure sand to black fen (a deep, non-acid peat soil) were used; to effect a comparative kill a higher concentration was required in the latter than in the former. When 'DD' was injected at the 9-in. level, a 95 per cent reduction in plant infection has been achieved under field conditions in sandy soils. Recent laboratory experiments have shown that better results may be achieved when injection takes place at the 3-in. level. Experiments involving the use of soil 'seals' have resulted in a 99 per cent reduction in plant infection.

The treated areas should be left undisturbed for a considerable period; also a full crop rotation should intervene before host crops are again exposed to attack. 'DD' has marked phytocidal effects, and seed potatoes have been killed when planted within seven days of soil treatment.

'DD' has been effective at a wide range of temperatures (33°–75° F.) and also in soils which have been air-dried or contain up to 40 per cent moisture by weight.

Slightly more ethylene dibromide than 'DD' was necessary to produce a comparative kill. The effectiveness of 'Dowfume G' is considered to be due to the methyl bromide present.

Weed control was also obtained by the use of 'DD' both in England and Southern Rhodesia. In England the plants controlled were all perennials with an existing root system at the time of soil treatment. Control was only obtained on land in Rhodesia which was treated and 'sealed', resulting in one instance in a 100 per cent control of ropoko grass (*Eleusine indica*, Gaertn.).

'DD' kills a number of soil pests, including wireworms, cutworms and centipedes. Although it is cheaper than all the other fumigants tested, the quantities required to obtain control of potato eelworm are such that the cost of treatment is still too high for economic use in England.

We would like to record the discovery of viable cysts of *Heterodera rostochiensis* adherent to soil on seed potatoes imported into Southern Rhodesia from Scotland. From two fields in Lincolnshire on which potatoes had not figured in the crop rotations for eleven years, small numbers of living larvæ were recovered from cysts of *Heterodera rostochiensis*.

A full account of this work will appear in the near future.

What is a Dialysate?

THE meaning of the word 'dialysate' as defined in the Oxford Dictionary is indeed apt to induce mental confusion. It did so recently in my own mind, when I had to struggle through an American patent specification, in which the term was actually used in its Oxford Dictionary sense. In my opinion, as well as in that of my collaborators, Dr. Pirie is quite right, and his discussion[1] supports our decision to use the term 'dialysate' for the part which dialyses through the membrane.

With regard to the part of the system retained by the membrane, Dr. Pirie agrees that the term 'colloid' is unfortunate; this is so because that part need not be a colloid at all. Might I propose the use of the widespread and comprehensive word 'residue'? This term does not admit of any ambiguity, and applies equally well to the processes of distillation, sublimation and even to that of filtration.

SCIENCE AND TECHNICAL EDUCATION IN GERMANY

International Congress for Technical Education

AN international congress of especial interest and significance was held at Darmstadt during July 31–August 9, under the auspices of the Technische Hochschule and with the full and generous co-operation of the American Military Government. For the first time in many years a large gathering of men of science and educationists were able to meet in Germany in free and open concourse. In spite of the difficulties of travel, more than fifty foreign visitors were able to be present, in addition to nearly five hundred Germans who came from all parts of Germany, including a small number from the Russian Zone. Fifteen British representatives were present. It was an experience which was of absorbing interest, especially for the insight which it gave into the present mental attitude of the teachers of science in Germany and into the physical conditions under which they must now carry on their work. The latter is the easier to describe. The universities and *technische Hochschulen* have suffered very severe losses of buildings and scientific equipment by the War, text-books are almost unobtainable, the teaching staff has been drastically reduced and, moreover, many—especially in the American Zone—are still awaiting trial by denazification courts. Those who are left are struggling, with a spirit which is wholly admirable, to provide a higher education to as many as possible of the greatly swollen numbers of students.

As in Britain the War has interrupted the education of many young men and women, and the influx of these into the universities has strained beyond the breaking point the very small resources of German higher technical education. It was with this background that the Darmstadt Technische Hochschule, largely through the energy of its rector, Prof. Richard Vieweg, called together this congress of representatives of technical colleges and industry.

The programme was arranged to discuss four main themes: (1) technics as an ethical and cultural opportunity; (2) the present state and trends of development in technical education throughout the world; (3) the admission of students to universities as related to social problems; (4) the exchange of professional ideas. Perhaps the best way to describe the spirit in which this programme was tackled is to quote in full the very moving inaugural address given by Prof. W. Brecht: "Seen from a distance, every university gives the impression of being a well-balanced institution of strong intellectual life emanating from the university as a whole. But from close at hand you discover that the specific character of the college is due to the manifold subjects, characters, temperaments and peculiarities of the teachers and to the versatility resulting from all these many shades of differences. Thus a problem of great weight may remain unsolved for a long time owing to the tension of discrepancies, until all of a sudden you realize that somewhere else, nay, everywhere, the problem has grown beyond personal solution and must be turned over to universal handling.

"This is the first time that a Technische Hochschule has opened her doors and made an appeal to the world of science as a whole, in order to bring a problem of vital importance before a great intellectual tribunal. This attempt, as well as the nature of the problem, are born of the present time.

"The exterior of the Technische Hochschule has been destroyed. All that is left are a few disconnected, separate buildings in an ocean of ruins, the remains of a city that was fatally wounded by the war. But harder to bear than the difficulties of reconstruction is the utter loneliness of the present and the sorrow caused by the obscurity of events that still envelop her in a veil that makes her aims and desires invisible to those who are standing without. Though still lacking in strength, she has raised her voice, hoping that it will pierce the dark wall surrounding her. She is not calling for help. She is fully conscious of the heavy burden of the past, and has no other desire than to prove that she wishes to live in order to be able to do her part in the good work.

"Sometimes things only seem to be good. When we are striving so earnestly and decisively for purity of intent, the good sought for must be genuine. Thus the call of our Technische Hochschule is at the same time a summons to solve a vital problem. The problem in question is how to educate the youth of to-day that will in the future apply the findings of natural science so that applied science, this form of the human intellect, now expressed in superhuman dimensions, may not glide farther into those icy regions, where the emotions of the heart are eliminated. How can our students be led to employ science, this truly noble instrument, in a manner worthy of the dignity of the human race?

"There is no doubt that technical schools and high schools have succeeded in giving their students the benefit of excellent technical training. There are people who say the success was too complete. For technical inventions have changed our lives fundamentally even so far as to influence the spiritual lives. There have before now been men, who saw danger looming up in this unprecedented development, voices warning us because science and the scientific way of thinking had become too strong and too independent and had thus lost all ties that should have bound them to the common roots of culture.

"However, we do know that the technical mind in itself is not evil. It is clear and precise and here as nowhere else, every step of its evolution is dependent on uttermost purity. Therefore technical science in itself is not evil. Its absolute value is determined by its aim, and not by the direct aim, but by the final, deepest ends it is to serve. Therefore we must dig down to the roots and we must penetrate into the borderland in which originate the possibilities of good and evil. Greater knowledge as to the peril involved and the danger emanating therefrom should raise technical thought and technical work into an atmosphere impenetrable to contamination and suited to the true nature of science. And it is this purpose that the education of our students should try to serve. This is a great and difficult task and as yet there are to be found but the very faintest attempts at such education.

"But we hope that this meeting of men of science and learning may assist in clarifying our aims and finding the means of putting them into effect."

Papers by English authors which were read and discussed at the congress were: "Science as a Means of Christian Teaching", by A. Cameron, Cambridge; "Technical Education at Cambridge University", by D. B. Welbourn, Bedford; "Practical Training of Professional Engineers in England", by Sir Arthur P. M. Fleming and J. T. Kendall, Manchester; "Neuere Anweisungen und Formeln zur Bestimmung der zulässigen Belastung von Pfahlgründen", by C. Carty, London; "Engineering Education in England", by J. W. Bondi, London; "Remarks on Calculating Machines and Mathematical Tables", by L. J. Comrie, London.

Altogether some two hundred papers were read and discussed at the congress, some in the full session and some in the various sections. In addition, time was found for a large amount of informal discussion and lively argument. Nor was the social side forgotten; in addition to official receptions and informal *Bier Abende* there was an excursion to the lovely village of Lichtenberg on the Sunday, a performance of Bach's "Die Kunst der Fuge", and a performance of the new opera by Carl Orff, "Der Mond". This last is an artistic masterpiece, and was beautifully performed; but in its macabre and morbid outlook one seems to sense the subconscious hopelessness and tragic philosophy of the Germans to-day. This feeling of heroic tragedy has undoubtedly bitten deeply into the German soul; and after living for just a week in the ruins of Darmstadt and sharing, if only for a short time, in the present German way of life, one can realize how this must be. The congress was undoubtedly of inestimable value in helping to dispel a little of this gloom and uncertainty about the future, and its organisers were almost embarrassingly grateful for the presence and participation in the discussions of the foreign visitors. We, on our part, were equally grateful for having the opportunity to meet and talk with Germans who have miraculously kept safe, through the years of Nazism and the final ruin of their cities and intellectual life, a spark of intellectual freedom and probity and a capacity, one hopes, for rebuilding a new and more civilized Germany.

There is no space here to review the many papers presented at the congress and to record the discussions and the resolutions which were adopted. A full report of these will be published by the Technische Hochschule, Darmstadt. JAMES T. KENDALL

Berlin Technical University, 1947

THE Technische Hochschule in the Charlottenburg district of Berlin is one of the best-known institutions of its type in Germany and, like other universities in the British Zone, is now functioning as actively as circumstances permit, under the supervision of the Education Branch of the British Military Government. The following impressions are the result of a recent visit to the British sector of Berlin, during which the writer was engaged on lecturing to German students on behalf of the Control Commission for Germany. The observations are chiefly of a general character, but include a certain amount of detail appertaining to the writer's own field—physics.

During the War, the Technische Hochschule was extensively damaged and none of the main buildings remained entirely unscathed. The library was completely destroyed. In April 1946, when the surviving buildings were re-opened, the name was changed to Technische Universität. The main policy, formulated by the British authorities, is administered by a Control Commission liaison officer who deals with all matters concerning the Technical University and its relation to the broad educational system. The internal administration is carried out by a senate, which consists of fourteen members of the professorial staff, under the guidance of the Rektor, Dr. Walther Kucharski, who was appointed directly by the Control Commission.

At present the total number of students is 2,096 (1,850 men, 246 women), of whom 191 are non-German. There are the usual departments covering all branches of pure and applied science, and it is interesting that one of the most highly developed studies is architecture, which possesses a separate faculty and attracts large numbers of students of both sexes.

The students for the most part pursue their studies with an assiduity which is truly remarkable when considered against the forbidding background of German life. The gravity of the food situation has caused widespread 'black market' activity, and all sections of the population are compelled to participate to some extent if they wish to supplement their meagre rations. In addition to this problem (which confronts everyone), the students are handicapped by an acute shortage of text-books, note-books, stationery and similar material requirements. In spite of these adverse circumstances, great keenness is evident, coupled with receptiveness of mind and a mature, critical attitude towards educational matters. A marked sense of responsibility is noticeable at sessions of the Student Parliament, which has a fairly elaborate constitution and, as might be expected, is regarded as an essentially serious organisation. Invariably the attendance is large and the agenda lengthy, the various issues being debated in characteristically earnest fashion. There is, of course, the other side of the picture. The lighter side of student life is enjoyed with exuberance and vitality, a fact which is illustrated most effectively by the athletic meetings, where the considerable expenditure of energy appears to contravene any conservation principle!

So far as teaching is concerned, the main problems are inevitably those of accommodation and apparatus, and the experimental sciences, in which laboratory work is an essential part of the curriculum, are most seriously affected. Apart from bomb damage and the confiscation of all equipment connected with prohibited research, there have been heavy losses due to looting. In the huge main lecture theatre of the physics department, all the rows of seats and the electrical fittings were removed bodily. Owing to the scarcity of apparatus, there are virtually no laboratory facilities for advanced students, and overcrowding is unavoidable in the few laboratories which are in use. In the chemistry department, added difficulties are caused by the absence of fume cupboards together with inadequate ventilation systems. In the physics department the first-year laboratories are reasonably well equipped with the familiar experiments in general physics, heat, electricity and optics; neat design and high-quality workmanship are apparent in many of the instruments, but it is significant that there are no stop-clocks. Each experiment requiring a time measurement is provided with a device incorporating a revolution counter and a tiny synchronous motor driven via a transformer from the A.C. mains supply. A serious hindrance to laboratory work is the activity of the ubiquitous pilferer. In a metre bridge set-up, for example, most of the components have substantial 'black-market' value, and unless precautions are taken to safeguard the apparatus there is a high probability that it will be found one morning in a somewhat despoiled state. Experience has similarly shown the extreme undesirability of leaving electric lamps in accessible positions.

Considerable progress has been made in building up the library again, but little can be done to improve the text-book situation. In the Western Zones of Germany there is no paper available for the printing of scientific books, although the position of journals is slightly better. The *Zeitschrift für Physik*, for example, has just reappeared under the editorship of von Laue. A few copies of British and American scientific periodicals have found their way into the library, but the impossibility of payment prevents a regular influx of foreign literature.

Similar conditions are encountered at the Heinrich Hertz Institut für Schwingungsforschung, which is associated with the Technical University by virtue of the fact that its director, Prof. G. Leithäuser, is a member of the staff, and of the senate, of the University. This Institute is concerned with the training of engineers in radio communications and allied fields, and possesses facilities for a small amount of research. All work is, of course, subject to the usual Military Government scrutiny, and no micro-wave equipment is allowed. Suitable apparatus for teaching purposes is in very short supply and the number of available experiments is thus severely limited; one class of twenty-four students is obliged to work in groups of six as there is sufficient apparatus for only four experiments. The main lines of research are: defects of mirror systems, the design of large horn loudspeakers for low-frequency reproduction and various radio circuit problems. A pulsed transmitter (wavelength range 30–100 metres) is being designed for ionospheric investigations.

So far as research in physics is concerned, facilities at the Technical University are practically non-existent, and of the three professors, C. Ramsauer, H. Kallmann and R. Frerichs, the two latter are supervising small groups working at the Kaiser Wilhelm Institut in Dahlem. This is situated in the American sector and therefore all projects are submitted to the American authorities for approval. Prof. Kallmann, in addition to theoretical work in wave mechanics, is working on the detection of α- and β-particles by a scintillation method, using organic fluorescent materials. The scintillations are recorded by a photo-tube and the responses are amplified and shown on a cathode-ray oscillograph. Prof. Frerichs is investigating the properties of cadmium sulphide photo-cells embodying photo-conducting strips about 1 cm. in length. Interesting results have been obtained with β- and γ-radiation, and further experiments are being carried out with X-rays.

As a concluding remark, it may perhaps be appropriate to mention one of the most notable features of academic life, namely, the universal eagerness for contact with the world outside Germany and in particular with Great Britain. There are many reasons why such schemes as student exchanges can take place on only a small scale at present; but a few students and lecturers from Germany have already visited Great Britain under the auspices of the International Student Service, and it is to be hoped that many other visits of this nature will be made possible in the future.

B. DONOVAN

German Physical Society in the British Zone

Autumn Conference

An autumn conference of the German Physical Society in the British Zone was held during September 5–7 in the University of Göttingen. This conference gave striking evidence of German recuperative powers under considerable material difficulties, for it was attended by some five hundred physicists, and a formidable total of fifty-eight original papers was read. The conference was declared open by the president, Max v. Laue, and at this opening session the assembled members and visitors were greeted by Dr. R. Fraser on behalf of the Research Branch of the C.C.G. Although technically a British Zonal conference, in effect it was to some extent a meeting of the Physical Society for the whole of Germany, since delegates were also present from the French, Russian and American Zones. The younger generation was strongly represented and actively contributed, a fact calling forth the approval of many of the older German physicists. There is no doubt that organised physics in Germany has now recovered from the stagnant aftermath which followed defeat, and active research is being prosecuted from many centres.

Considerable satisfaction was expressed by many Germans present at the fact that a number of invited guests had arrived from abroad to read papers. These were: A. Michels (Amsterdam), V. L. Jordan (Copenhagen), B. Pippard, E. H. Sondheimer, D. Shoenberg (Cambridge), S. Tolansky (London), J. G. Wilson (Manchester), and all were received with warmth and given a particularly attentive hearing. The number of papers read was sufficiently large to enable the emerging pattern of interests in the post-war physics of Germany to be appreciated. Nuclear physics (in the wide sense) accounted for fifteen contributions divided into cosmic rays (5), nuclear reactions (5) and isotopes (5). There were nine papers on optics and spectroscopy, nine on metallic conduction and magnetism, and nine on acoustics. The remaining sixteen papers ranged widely, from quantum mechanics to diffusion pumps.

It will be gathered from this distribution that the pattern of interests is little different from what might have been expected from any German conference of pre-war days, and indeed the traditional emphasis so characteristic of Germany is well reflected. A matter of some considerable interest is the emergence of quite a number of unfamiliar place names as the centres of research. This may possibly be associated with war-time evacuation measures carried out to avoid the intensive bombing attacks, or perhaps for other reasons. In addition to many contributions from old-established and well-known university centres, papers were read about researches which had been carried out in such unfamiliar places as, for example, Hechingen, Weissenau, Tailfingen, Honnef, Horb, Markenkirchen, etc. It is stressed that these contributions were largely of the academic type normally expected from universities or associated establishments.

On each of the three days of the conference, a general review of a specific topic was given; these aroused a good deal of interest. The first, which constituted the opening paper of the conference, was delivered by W. Heisenberg. It was a clear and concise factual statement of the present position in cosmic ray research, and was a valuable and comprehensive contribution. The second general review was by K. Wirtz. The author was a member of a research team engaged on the German uranium project, and in his paper he surveyed the limited achievements of the Germans in this direction. The third general paper was delivered by E. Meyer, who surveyed recent developments in acoustics in a comprehensive manner.

In addition to the formal papers read, some specially arranged symposia were held, the visitors from Britain taking part respectively in those on metallic conduction and interferometry. The social programme was indifferent, which was inevitable in view of the difficult conditions in Germany to-day. In view of these quite serious difficulties, the conference must undoubtedly be considered as quite an administrative achievement and augurs well for the future of physical research in Germany, despite the very serious shortage in the current materials of research.

S. TOLANSKY

Statistical Methods

THE first meeting of mathematical statisticians ever held in Germany took place on September 3–4, 1947, in Göttingen. It was attended by British statisticians who had been invited in an endeavour to overcome the difficulties which German mathematicians have experienced by having been cut off from foreign literature for a long time. The losses suffered by libraries in Germany and the impossibility of replacing their stocks contribute to the desire of German scientific workers to resume personal relations with British (or other) contemporaries.

The first meeting was opened by Dr. H. Münzner, professor of theoretical statistics in the University of Göttingen. Prof. P. Riebesell (Hamburg) then gave a critical account of the methods of *Grosszahlforschung*, showing that this version of the statistical analysis of mass production is either trivial or false. He discussed the relation of the normal curve to empirical distributions and suggested a test of the significance of two or more observational modes based on the idea of confidence limits (*Mutungsbereich*). S. Vajda (London) gave a talk on "The Algebraic Basis of the Analysis of Variance Method" in which he derived well-known formulæ for the tests of effects and interactions of any order by the use of orthogonal polynomials, and pointed out how various possible but different definitions of effects were due to different algebraic constructions (see *Nature* July 5, p. 27.)

In the afternoon, Miss M. P. Geppert (Kerckhoff Institute, Bad Nauheim) proved by examples that in estimating a parameter from a sample none of the three central measures, mode, mean, or median, of the fiducial distribution needs coincide with the maximum likelihood estimate. Prof. O. N. Anderson (late of Sofia, now at the University of Munich) gave an account of the problems of inverse probability and fiducial limits, stressing the necessity for deriving formulæ pertinent to a model "without replacement"; he also discussed a formula which should take the place of the t-distribution in the case of relative frequencies (which are not normally distributed) for small n and $p \neq (1 - p)$.

On September 4, H. L. Seal (London) spoke on non-parametric tests and discussed some of them from the point of view of errors of the first and second kind. Prof. H. Münzner (Göttingen) introduced and solved an integro-difference equation which arises in the description of a 'cascade'-process where a particle multiplies k-fold, with probabilities dependent on k, at times t, the "intensity of multiplication" being dependent on t. Finally, Dr. E. Sperner (Oberwolfach) gave an account of his method of expanding meteorological functions in terms of eigenfunctions for the purpose of extrapolation.

An animated discussion took place in the afternoon at the Geophysical Institute, where the participants met by courtesy of the director, Prof. J. Bartels, whose notion of "persistence tendency" applied to time series (see *J. Amer. Stat. Assoc.*, June, 1940) gave rise to talks on a great variety of subjects, ranging from weather forecasts to the Heligoland explosion (see *Nature*, September 13, p. 350), seismic graphs of which were exhibited.

Many representatives of German statistics were, of course, unable to attend the meeting, but there was much interest in its proceedings. It was felt by all that the comparison of results obtained in ignorance of similar work done in other countries may prove stimulating, though at present Germany has scarcely anything to show which could compare with the fundamental progress achieved in Great Britain and the United States in the last twenty-five years or so. To facilitate the exchange of ideas it was decided to start work on an English–German dictionary of statistical terms, and to supplement it with proposals for a universal notation. Suggestions will be welcomed by Prof. H. Münzner (University of Göttingen, Germany, British Zone), or by the British visitors to the meeting.

S. VAJDA

Petroleum Geology

FOR the first time in the course of fifteen years, a meeting of those interested in oil geology was held in Hanover during September 9–11, about five hundred geologists and geophysicists being present. The State Secretaries of the administrative province, representatives of the Military Government, and numerous foreign guests were welcomed by Prof. Bentz, director of the Oil Department of the Reichsamt für Bodenforschung.

During the last fifteen years, several thousand wells have been drilled in north-western Germany, which have considerably increased the theoretical and practical information about the deep subsurface. The main part of the meeting consisted of reports from twenty-six German oil-fields. Their exploration by means of the most up-to-date methods has not only increased the production of the oil industry considerably but also provided much geological and geophysical material, which has helped to clarify the complicated tectonic, stratigraphic and facial conditions of the north-west German Saxonicum. Of the numerous Mesozoic rocks with oil-bearing possibilities from which the production of the north-west German oil-fields is derived, preference is still given to the Zechstein as the source rock of the oil; this hypothesis, however, was by no means placed in the foreground as the only one. The German oil industry owes its successes to this positive scientific attitude. It is only necessary to mention here the importance of the Ems district for German economic life. With regard to its reserves, this district is among the most important German oil provinces, and is thus also an important political factor.

Twenty oil-fields of north-western Germany are associated with salt domes, fifteen being of the flank type and five of the crestal type. Six fields are located on anticlines; for example, those of the Ems district. The source rocks are the main dolomite and the porous shale of the Middle Zechstein, the coral oolite of the Malm, the shell banks of the Wealden, the débris layers of the Neocomian, the chalk of the Upper Cretaceous, the sandstones of the Rhætic, the Lower Liassic, the Lower Dogger, Cornbrash, Valendis, and Lower Eocene. Almost all the fields are poor in gas content and subject to edge water drive. In 1946 the total production amounted to about 4,380,000 barrels.

In April 1947, geophysical results of a general interest were obtained from the blowing-up of the fortifications of the island of Heligoland (see *Nature*, September 13, p. 350). The depths of the North German area of sedimentation were established as approximately 3·1–6·2 miles, while the top of the sima near Göttingen was encountered at a depth of 17 miles, and at 25 miles at the edge of the Alps. The thickness of the continent, hitherto assumed as 37–62 miles, was thus considerably reduced; while fundamentally new knowledge of the major tectonic movements of the earth's crust was obtained.

Thirty-seven reports on the tectonics and palæography of Saxony, geophysical and petrographic methods of investigation, production engineering, and micro-palæontology afforded a comprehensive view of the state of German oil geology.

Many geologists were greatly stimulated by the meeting, and the synthesis between scientific research and its practical application was repeatedly emphasized. This synthesis alone has helped to achieve the results described during the meeting. A full report will be published in due course in the *Zeitschrift der Deutschen Geologischen Gesellschaft.*

An outcome of the meeting was the decision to found a Deutsche Gesellschaft für Mineralölwissenschaft and a Deutsche Geologische Gesellschaft for the British Zone.

W. Rühl

THERMIONIC EMISSION FROM OXIDE-COATED CATHODES

Oxide-coated cathodes have been used by the million for many years, but the explanation of the exact mechanism of the thermionic emission from them still presents many interesting physical problems. The summer meeting in London on June 14, arranged by the Electronics Group of the Institute of Physics, on recent work on such cathodes was most opportune, since the war-time use of the cathodes under pulse conditions, and the influence of recent theories of the properties of barrier-layer rectifiers and semiconductors, have stimulated further experimental and theoretical work, and are leading to a revision of views previously held.

Dr. F. A. Vick, of the University of Manchester, began the opening paper by summarizing the position in 1939. Activated cathodes were believed to consist of a mixture of barium and strontium oxides on a metal (normally a nickel alloy) core. Near the surface, strontium oxide was thought to predominate, and adsorbed on the surface a layer of barium, of concentration depending on the equilibrium between diffusion towards the surface and electrolytic movement towards the core during current flow. The high efficiency of oxide cathodes was supposed to be due to the lowering of the effective surface potential barrier by the adsorbed barium[1,2,3,4], analogous to the action of electro-positive layers on tungsten. Earlier workers had suggested[5,6] that the observed electron emission is determined by the potential barrier at the core-oxide interface, but by 1939 the role of the core had been relegated to assisting in the dissociation of oxides to provide some free barium.

The war-time use of oxide cathodes in valves used for pulse work directed attention to the fact that the peak saturated current in microsecond pulses could be many times (for example, 100) the normal saturated current at the same nominal temperature. Sproull[7] described careful experiments on the current-decay characteristics of the cathodes, with anode voltages kept constant for times varying between 100 and 2,000 microsec. and then switched off for times long enough for the cathode to recover. The saturation current rose to an initial high value and then decayed to an asymptote one-fifth to one-fifteenth of the initial value. Sproull suggested that as soon as the thermionic current starts to flow through the oxide, the concentration of the adsorbed barium layer commences to decrease from the equilibrium value under zero current to a new value depending on electrolytic movement through the oxide, and leading to a higher effective work function. Sproull inferred that electrolytic movement is easy through the oxide crystals but difficult across the crystal boundaries. Dr. Vick expressed the view that Sproull's theory is not the whole explanation of pulse effects, though some electrolytic movement of barium may be a contributory factor.

More recently, E. A. Coomes has published[8] an account of his work on the pulsed properties of oxide cathodes. He produced evidence to show that (i) a cathode giving good results under D.C. conditions is not necessarily a good pulse cathode, (ii) there may be a large temperature rise when heavy currents are drawn, (iii) a major limitation on the maximum pulse current is the onset of 'sparking' or 'flashing', (iv) the effect of the composition of the core metal on pulse properties may be considerable, pure nickel probably being the best. Coomes suggests a different reason for the enhanced emission, namely, that the electrons thermally excited into the conduction band of the oxide semi-conductor during the period between pulses are swept out during the pulse and added to the normal emission for a short period.

Dr. Vick went on to discuss work by Eisenstein and his colleagues on the use of X-rays to study the structure of oxide cathodes[9,10]. The results show, *inter alia*, that the crystal size of the oxide depends mainly on the maximum temperature reached during activation, that during life the composition of the surface layers becomes nearly pure strontium oxide (confirming previous results), and that special interface compounds are often formed at the core-oxide boundary, associated with an interface resistance *vs.* current characteristic similar to that exhibited by barrier-layer rectifiers. These and other considerations have led some workers to picture an oxide cathode as made up of the following sections: (*a*) metal core, (*b*) rectifying barrier layer, with direction of easy flow towards the core, (*c*) an excess semi-conductor with dispersed interstitial barium, (*d*) a region of strontium oxide with interstitial barium, (*e*) a surface potential barrier, the height of which may be influenced by an adsorbed barium layer. To determine the relative importance of the various factors and to fill in the details will require extensive work, both theoretical and experimental. Dr. Vick concluded the opening paper by outlining part of the programme of work recently commenced at the University of Manchester. C. A. Walley is applying the mass-spectrograph technique to identify the positive and negative ions emitted from oxide cathodes during activation and at all stages of life, and to correlate the ion currents with cathode structure and thermionic properties. W. Grattidge is studying methods of forming oxide cathodes without starting with the carbonates or using an organic binder, the aim being to obtain coatings with relatively simple and reproducible physical structures.

The next paper was contributed by Mr. D. A. Wright, of the Research Laboratories, General Electric Co. Ltd., Wembley, who dealt first with the factors affecting total coating resistance. He has applied the Mott[11] and Schottky[12] theories of barrier-layer rectification to the core-oxide interface. A potential barrier is to be expected at the interface, the difference between the work functions of the metal and of the oxide semi-conductor giving its height. The flow of electrons from core to oxide is then determined by barrier height, temperature, potential gradient through the barrier and the electron mobility in it. Mr. Wright's experiments using a magnesium–nickel core and a single probe embedded in the oxide have confirmed the existence of the barrier layer, with an effective resistance at low currents of 2–4 ohms per sq. cm., rising to tens of ohms at saturation. Hence at high currents the P.D. across the barrier layer can rise to some hundreds of volts, possibly leading to dielectric breakdown. The barrier layer may limit the emission available from the cathode, and its capacitance introduces a time-constant affecting changes in emission. Fineman and Eisenstein[10] have shown that the true coating resistance away from the barrier layer is of the order of 1 ohm per sq. cm. To lower the true coating resistance in the presence of a high-resistance barrier layer would give little overall gain in performance, but if the barrier layer resistance could be lowered at the same time, a considerable gain would be possible.

With a magnesium–nickel core, the height of the potential barrier at the core interface has been estimated to be about 0·7 eV. Mr. Wright's recent calculations show that the bottom of the conduction bands in BaO, SrO and CaO is not more than about 0·5 eV. below the zero-level. Conductivity measurements show that the impurity-levels of interstitial barium in barium oxide are between 1·0 and 1·5 eV. below the bottom of the conduction band. This gives a work function of 1·0–1·3 eV. Since this is of the same order as the observed work function for an oxide cathode, it indicates that any adsorbed barium on the surface has a small influence only on the work function. This is in agreement with the results of Nishibori and Kawamura[13]. In order to reconcile the value of the work function of the oxide with 4·6 eV. for nickel and the barrier height of 0·7 eV., it seems necessary to assume the presence of barium at the core-oxide interface.

Treating the observed emission as from an excess semi-conductor, assuming that the concentration of interstitial barium is 5×10^{17} atoms per c.c., the resistivity at 700° C. is calculated to be 300 ohm. cm., and the saturated emission 50 amp. per sq. cm., agreeing reasonably well with experiment. Methods of reducing effective resistance are being explored in the G.E.C. Research Laboratories.

Mr. Wright concluded his paper by suggesting a reason for the most effective cathodes being those with approximately equimolecular proportions of barium and strontium oxides. The reasoning is based on a minimum work function for interstitial barium in the surface layers of strontium oxide.

These two opening papers provoked a lively discussion which raised many points of detail for which there is no space in this brief summary. Mr. T. J. Jones (Admiralty Signals Establishment) directed attention to additional arguments in favour of an adsorbed barium layer being a predominant factor in controlling the effective thermionic emission. In one of his experiments[14] the outer layers only of an activated cathode were removed in a vacuum; this caused the emission to fall to about one thousandth. Subsequent operation at a suitable temperature restored the activity. Mr. Wright said that his own work and that of others had now stressed the importance of the core-oxide interface.

The last paper was contributed by Mr. A. J. H. Darlaston, of the Cosmos Manufacturing Co. Ltd., who gave a brief account of the preparation of oxide cathodes.

A fuller account of the proceedings at the meeting will be published in *The Journal of Scientific Instruments*. F. A. VICK

TYPHUS RESEARCH

IN recent years research upon typhus has provided one of the best examples of the beneficent effects of international co-operation in scientific work. By agreement with workers in the United States and Canada, publication of many aspects of the work done on typhus at the National Institute for Medical Research, London, and at the Royal Army Medical College Emergency Vaccine Laboratory, Everleigh, Wilts, has been withheld. A full account of important parts of this work has now been issued*.

The researches of twelve workers are here recorded and Dr. C. H. Andrewes contributes a general introduction in which he explains that the report is not a comprehensive treatise on the clinical and pathological aspects of typhus, although it contains useful descriptions of these aspects of the disease, and especially of the Naples epidemic, which occurred between January and March, 1944, and is likely to have considerable historic interest. The report consists of five sections. Section 1 deals with the toxicity of two sulphonamides (*V* 147 and *V* 186), the highly promising activity of which against the murine type of typhus in mice had been studied earlier by Andrewes and his collaborators. Section 2 discusses in great detail the chemotherapeutic trials of these drugs in North Africa and at Naples, and the pathological studies associated with this part of the work. The two sulphonamides failed to fulfil the expectation raised by the earlier results obtained in mice, and the possible reasons for this failure are discussed. Section 3 describes a quantitative test for neutralizing antibodies against typhus Rickettsiæ. Section 4 discusses the comparison of four murine typhus vaccines in the laboratory and gives methods for the preparation of these vaccines. Section 5 compares the antigenic structure of a murine strain of typhus Rickettsiæ with that of a strain of epidemic typhus Rickettsiæ. The report concludes with two appendixes, one giving illustrative case reports and the other a list of drugs tested for chemotherapeutic activity against experimental typhus infection in mice.

---

* Medical Research Council. Special Report Series, No. 255: Chemotherapeutic and Other Studies of Typhus. By M. van den Ende, C. H. Stuart-Harris, F. Fulton and J. S. F. Niven, with C. H. Andrewes, A. M. Begg, W. J. Elford, M. H. Gleeson White, W. L. Hawley, K. C. Mills, F. Hamilton and C. C. Thomas. Pp. ii+246+11 plates. (London: H.M. Stationery Office, 1946.) 12*s*. 6*d*. net.

It is impossible, of course, in a brief space to do more than indicate, as the preceding paragraph attempts to do, the solid value of every page of this report. It is an indispensable addition to the library of every worker on typhus and contains much that will interest the historian. Reading between the lines, one gets glimpses of Naples early in 1944, when the Italian civil authorities helped by their complete co-operation, although one of the immense difficulties encountered was the concealment of illness by the Italian community. The photograph published of an Italian deep underground air raid shelter, coupled with a little imagination and a dash of memory of Italy in happier days, makes it easy to visualize how a typhus epidemic can play havoc under the conditions then prevailing. The story of the dramatic effects of D.D.T. upon the lice vectors of the disease has been told elsewhere. Dr. C. H. Andrewes mentions that, when the method of intranasal inoculation of mice with material containing typhus Rickettsiæ was first used, all five of the workers using this method at Hampstead became infected, "fortunately with murine, not epidemic, typhus", and nine others working at Everleigh were also infected; but after the invention by van den Ende of a special inoculation box only one other worker was infected at Hampstead during the ensuing two and a half years, while none was infected at Everleigh. This gives an idea of the risks taken by these workers. Although there is still no specific drug which has a specific action on typhus Rickettsiæ, nobody will doubt that one will eventually be found. When it is found, it seems likely that the study of its use will provide valuable information about possible chemotherapeutic methods of attack upon other organisms which have so far resisted all drugs used against them. As this report says (p. 126), modern chemotherapy of bacterial diseases is supposed to depend largely upon interference with essential metabolic processes of the organisms, but a similar basis for attacks on the virus and Rickettsial diseases may be impossible, because these organisms depend upon "parasitism of the enzymes and essential metabolites of the host's cells". Perhaps future work, using this idea as a clue, will succeed in mastering these causes of this devastating disease.

G. LAPAGE

JAMES HUTTON: GEOLOGIST AND AGRICULTURIST

THE first ordinary meeting this session of the Royal Society of Edinburgh was held on November 3 and took the form of a commemoration of the hundred and fiftieth anniversary of the death of James Hutton [see also p. 694].

Sir Edward Bailey, who spoke on "James Hutton: Founder of Modern Geology: 1726–1797", devoted much of his address to Hutton's unpublished "Principles of Agriculture". He said that to anyone perusing Hutton's immortal "Theory of the Earth", it is clear he pictured his subject as a well-managed agricultural estate with a rotation of processes designed to maintain continuing fertility. One might therefore have expected to find in his agricultural treatise merely a disguised reproduction of his well-known geological tenets. Such is far from the case. Hutton, who spoke to geologists of æons, spoke to farmers of seasons and years. His object was "to make philosophers of husbandmen and husbandmen of philosophers".

The work, if published in its day, would rank among the classics. Its interest is comprehensive. For example, one sentence from a discussion of possible diversification of species by natural selection is remarkable: "Where dogs are to live by the swiftness of their feet and the sharpness of their sight, the form best adapted to that end will be the most certain of remaining, while those forms which are least adapted to this manner of chase will be the first to perish". It must be remembered that this was written by a man who died eleven years before Charles Darwin was born. Similarly, Hutton's account of selection of a pure line of rice, somewhere about the year 1710, by the Emperor Kang-hi, makes it difficult to realize that, when its author died, Patrick Shirreff, famous as pioneer-isolator of profitable strains of wheat and oats, was only six years old.

Hutton's writings on climate and chemistry, physics and metaphysics, are less valuable than his contributions to geology and agriculture; but through them all can be seen the working of a single great idea, a balance of the powers of Nature, which leads to never-ending cyclic continuity. If in one direction Hutton noted destruction, he always found in another direction proof of reconstruction. Thus, in geology, his unaided eyes told him how agents of erosion, under the influence of gravity, were slowly washing the continents down into the sea; while his reason assured him with equal certainty from available evidence that there was internal heat in the earth, which would presently re-elevate the consolidated debris high above the reach of the waves. Among Hutton's other famous contributions to geology may be mentioned the following: granite is an igneous rock, a claim based upon a number of veined contacts; geological processes of the past have been of the same kind and intensity as those of the present; the valley systems of the earth's surface have been sculptured by subaerial erosion operating through millions of years.

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Monday, November 24

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "Industrial Applications of Inductor Alternators" (to be opened by Dr. J. H. Walker).

Manchester Literary and Philosophical Society (in the Reynolds Hall, College of Technology, Manchester), at 5.30 p.m.—Dr. Metcalfe Brown: "Smoke Abatement" (Clayton Memorial Lecture).*

Tuesday, November 25

Institution of Post Office Electrical Engineers (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 5 p.m.—Colonel D. McMillan: "Hearing as an Essential Part of the Telephone Circuit".

Royal Anthropological Institute (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. W. L. H. Duckworth: "Some Complexities of Human Structure" (Huxley Memorial Lecture).

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Sir Harold Spencer Jones, F.R.S.: "The Development of Astronomical Instruments from Early to Modern Times". (Further lectures on December 2 and 9.)

Institution of Civil Engineers (joint meeting with the British Section of the Societe des Ingenieurs de France, at Great George Street, London, S.W.1), at 5.30 p.m.—M. A. Coyne: "Latest Developments of Dams and Hydro-electric Power Stations in France".

Illuminating Engineering Society (at the E.L.M.A. Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 6 p.m.—Prof. H. Hartridge, F.R.S.: "Recent Advances in the Physiology of Vision".

Society of Public Analysts and other Analytical Chemists, Physical Methods Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Third Annual General Meeting; Mr. B. S. Cooper: "Electron Microscopy".

British Esperantist Scientific Association (in the Department of Psychology, University College London, Gower Street, London, W.C.1), at 7 p.m.—Fourth General Meeting.

Society of Instrument Technology (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. D. Edmundson: "Electronic Developments in Instrumentation".

Wednesday, November 26

Physical Society, Optical Group (at Northampton Polytechnic, St. John Street, London, E.C.1), at 3 p.m.—Scientific Papers. (Members of the Colour Group are invited.)

Royal Microscopical Society, Technical Section (in the Hastings Hall, B.M.A. House, Tavistock Square, London, W.C.1), at 5.30 p.m.—Mr. J. V. H. Wredden: "Microscopy of Enamelled Wire".

Society of Chemical Industry, Microbiological Panel of the Food Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.15 p.m.—Papers on "Biological Stability of Processed Fish and Manufactured Fish Products".

Manchester Metallurgical Society (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Mr. E. W. Colbeck: "Some Metallurgical Problems in the Field of Atomic Energy".

Society for Visiting Scientists (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Dr. F. P. Bowden: "The Initiation of Explosives"; Dr. W. A. Wooster: "Synthetic Mineralogy".

Thursday, November 27

Linnean Society of London (at the G.-B. Studios, Film House, Wardour Street, London, W.1), at 5 p.m.—Films.

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Annual General Meeting; Prof. E. C. Titchmarsh, F.R.S.: "Analysis for Physicists" (Presidential Address).

Royal Institute of Chemistry, Manchester and District Section (in the Lecture Hall, Albert Hall, Peter Street, Manchester), at 7 p.m.—Dr. D. T. A. Townend: "Fuel and Chemistry" (Fourth Dalton Lecture).

Royal Photographic Society, Scientific and Technical Group (at 16 Prince's Gate, London, S.W.7), at 7 p.m.—Symposium on "Pictorialism and the Characteristic Curve" (to be opened by Dr. S. O. Rawling and Mr. G. Scott-Bushe).

Royal Institute of Chemistry, London and South-Eastern Counties Section (at the Public Library, William Street, Slough), at 7.15 p.m.—Dr. A. H. Lewis: "Some Aspects of Chemistry in relation to Agriculture".

Society of Dyers and Colourists, West Riding Section (at the Great Northern Victoria Hotel, Bradford), at 7.15 p.m.—Dr. P. Schulman: "Emulsions—Oil and Water Dispersal Mediums".

Friday, November 28

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Geophysical Discussion on "Electrical and Magnetic Effects of Marine Currents".

Royal Institute of Chemistry, London and South-Eastern Counties Section (at Isleworth County School, Ridgeway Road, Isleworth), at 7 p.m.—Mr. J. King: "Scientific Problems in Feeding a Modern Army in the Field".

Society of Dyers and Colourists (at the Technical College, Bradford), at 7.15 p.m.—Mr. M. O'C. Horgan: "Infra-red Drying".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. C. F. Powell: "Tracks of Charged Particles in Photographic Emulsions".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Dairy Chemistry (Grade III), and an Assistant Lecturer in Agricultural Chemistry—The Secretary, North of Scotland College of Agriculture, 41½ Union Street, Aberdeen (November 28).

Lecturer in the School of Physics and Applied Science, to deal principally with telecommunications—The Registrar, College of Technology and Commerce, The Newarke, Leicester (November 29).

Lecturer (with qualifications and experience in mechanical or production engineering and, preferably, a university degree) in the Engineering Department of the County Technical College, Wednesbury—The Director of Education (Dept. F.E.), County Education Offices, Stafford (November 29).

Lecturer in Physics in the Department of Physics Applied to Medicine—The Secretary, Middlesex Hospital Medical School, London, W.1 (November 29).

Assistant in the Department of Natural History—The Secretary, The University, Aberdeen (November 30).

Lecturer (temporary) in Zoology at Auckland University College, Auckland, New Zealand—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (December 1).

Lecturer in Applied Mathematics in the University of Cape Town—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (December 1).

Established Assistant Keeper (male) at the Botanic Gardens, Glasnevin, Dublin—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (December 5).

Control Chemist and an Entomologist, a Senior Control Chemist and a Senior Entomologist, in a survey team investigating pest infestation in Nigeria—The Under-Secretary of State, Research Department, Colonial Office, Palace Chambers, Bridge Street, London, S.W.1 (December 6).

Lecturer in Physics—The Clerk to the Governors, Woolwich Polytechnic, Woolwich, London, S.E.18 (December 6).

Lecturer in Social Psychology—The Registrar, The University, Leeds 2 (December 6).

Lecturer in the Department of Civil Engineering—The Registrar, The University, Sheffield (December 8).

Assistant Lecturer in Physics—The Secretary, University College London, Gower Street, London, W.C.1 (December 10).

Lecturer in Textile Engineering in the Department of Textile Industries—The Registrar, The University, Leeds (December 10).

Assistant Director in the Directorate of Telecommunications, and Divisional Telecommunications Officers (2), in the Northern and South-western Divisions—The Ministry of Civil Aviation, Establishment Division (B), 10 Fleet Street, London, E.C.4, quoting C.A.Est./1068 (December 11).

Research Assistant in Beekeeping—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow C.2 (December 12).

Professor of Applied Mathematics specialized in mathematical statistics or mathematical physics, in the Faculty of Science, Farouk I University, Alexandria—The Director, Egyptian Education Bureau, 4 Chesterfield Gardens. London, W.1 (December 12).

Lecturer in the Department of Chemistry in the United College, St. Andrews—The Secretary, The University, St. Andrews (December 13).

Assistant Chemist in the Plant Protective Chemistry Section—The Secretary, East Malling Research Station, East Malling, Maidstone, Kent (December 15).

Demonstrator in Pharmacology—The Registrar, The University, Leeds 2 (December 15).

Director of Safety in Mines Research under the Ministry of Fuel and Power—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2044 (December 19).

Principal Scientific Officer, a Senior Scientific Officer, and Scientific or Experimental Officers (2), in the Department of Physiology—The Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire (December 20).

Senior Principal Scientific Officer (Physicist) on the staff of the Joint Fire Research Organization of the Department of Scientific and Industrial Research and Fire Officers' Committee—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2050 (December 30).

Sir William H. Collins Professorship of Human and Comparative Pathology—The Secretary, Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.2 (December 31).

Professor and Head of the Physics Department of the Indian Institute of Science, Malleswaram, Bangalore—The High Commissioner for India, India House, Aldwych, London, W.C.2 (Bangalore, December 31).

Principal Scientific Officer or Senior Scientific Officer to investigate the chemical nature and fate during digestion of the different constituents of 'crude fibre' and of 'nitrogen-free extractives' of coarse fodders—The Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire (January 1).

Director of Museums, Museums Department, Malaya—The Director of Recruitment, Colonial Service, 15 Victoria Street, London, S.W.1.

Demonstrator in the Department of Bacteriology and Immunology—The Assistant Dean, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1.

Head of the Scientific Division—The Director of Research, British Boot, Shoe and Allied Trades Research Association, Satra House, Rockingham Road, Kettering, Northants.

Professor of Physiology—Rev. Father A. L. M. Danis, Faculty of Medicine, University of Ottawa, Ottawa, Canada.

Professor of Civil Engineering, and a Professor of Mechanical Engineering, at Maclagan Engineering College, Lahore—The High Commissioner for Pakistan, 15–16 Fitzhardinge Street, London, W.1.

SCIENTIFIC ORGANISATION AND MANAGEMENT

IN a recent broadsheet, "Recruiting Civil Servants", Political and Economic Planning commented, as the Select Committee on National Expenditure has done, on the comparative weakness of the administrative class of the Civil Service on questions of organisation and management. The same question receives some attention in a report on the reform of the higher Civil Service prepared by a special committee of the Fabian Society; and the operation of the Division of Organisation and Methods in the Civil Service together with its effect on the staffing of Government Departments has been examined during the recent session by the Select Committee on Estimates. The fifth report of the latter Committee (H.M. Stationery Office, 1947. 4*s.* net) takes a fitting place with the sixteenth report of the Select Committee on National Expenditure for the session 1941–42, and indeed with the report of the Haldane Committee on the Machinery of Government; it merits close study at the present time in view of the bearing of this question on the most effective use of trained man-power.

From a wider point of view, however, these two recent reports are equally important. The report prepared for the Fabian Society reaches the general conclusion that since the Civil Service is now expected to provide for overall planning and the control and guidance of certain industries, the time has come to review and reform its methods of recruitment and training, its organisation and management. There are differences of opinion as to how far even a reformed Civil Service can be expected to be responsible for the conduct of industry, but there will be little dissent from the view that the new duties and responsibilities which it is legitimately and inevitably compelled to assume make imperative some fresh review of its structure, recruitment and training. That much is implied in the criticism of the Civil Service which is current; and a great merit of these reports is that they dispel much of the confusion and inaccuracy of such criticism and focus attention on the true defects, notably those arising out of its size and slowness, in a way that facilitates constructive proposals. Moreover, they bring into the open those other defects of the present organisation of government for the consequences of which the Civil Service itself has frequently been unjustly blamed.

The purpose of the Division of Organisation and Methods in the Civil Service is to secure maximum efficiency in the operation of the Government's executive machinery, and, by the expert application of scientific methods to organisation, to achieve economy in cost and labour. The Committee on Estimates quotes in its report from a striking speech of the Right Hon. R. C. Casey to the Institute of Industrial Management in Australia describing the results and methods of an organisation and methods investigation into the administration of Bengal. That investigation showed clearly and logically that the whole administrative machine in Bengal was fifty years out of date, and the Commission then recommended how it could be brought up to date. That quotation alone indicates some of the possibilities, and the Select Committee on Estimates, in reviewing the Home Civil Service, points out that in view of the shortage of man-power and the increased participation of the central Government in economic and social affairs, it is imperative that specialized attention should be given to the adjustment and re-designing of the machinery of administration. The ideas of organisation and methods are not, of course, new; some were propounded by the MacDonnell Commission in 1914 and elaborated by the Haldane Committee and the Tomlin Commission. Nevertheless, it remains for effective use to be made of the recommendations of these bodies and the instrument already provided.

Pointing out that up to now the engineering and analytical approach of 'Organisation and Methods' has only been used to introduce simplification at lower levels, the Committee observes that it is at the higher level of the Government machine that defects may occur which will react throughout the Civil Service and cause wasted effort at each executive level. These defects can only be satisfactorily remedied by measures applied at the source. Moreover when, as at present, the activities of Government are altering rapidly, the whole pattern of administration has to be adjusted to meet the new requirements, and a distribution of duties according to function has become essential.

Little, however, has yet been done to apply such reorganisation at the top level as between different departments. What is needed is not a sporadic shifting of duties which may well result in equally bad overlapping elsewhere, but some modification of the present pattern of the administrative machine. That is already foreshadowed in the setting up of a single Ministry of Defence to co-ordinate the activities of the three Service Departments, and still more recently in the appointment of Sir Stafford Cripps as Chancellor of the Exchequer and Minister for Economic Affairs, and the establishment of a new ministerial committee on economic planning over which the Prime Minister will preside. The Lord President of the Council, it will be remembered, already exercises a considerable co-ordinating influence over the country's scientific effort.

Clearly, as the Select Committee recognizes, issues of constitutional importance are here involved, such as the limitation of departmental autonomy. While such issues can be dealt with only at the highest level, the Committee considers that it is a matter of urgency that these questions should be attacked scientifically and not as a series of piecemeal adjustments made whenever the strain on different parts of administration becomes intolerable. In such re-designing, the Division of Organisation and Methods should be planning the structure and machinery of Government rather than attending to its plumbing and maintenance. The Committee welcomes, therefore, the assurance that the Division is now being reinforced with a small group of officers who have already had some years of experience in considering machinery of government questions at a high level. Still more, it welcomes the establishment of a small committee consisting chiefly of permanent secretaries, with the head of the Treasury as probable chairman, and it suggests that this committee might be actively concerned with these alterations in structure which affect the whole Civil Service, provided the committee meets regularly and is strengthened by experts on administration from outside the Service where necessary.

These, in fact, may well be the most important recommendations of this searching report. If industry is to be urged to become more efficient, the Government must put its own administration in order. Insufficient thought has been given to adapting the machinery of government to its new tasks, as *Planning* has repeatedly urged.

This is not the greatest danger. As the Select Committee notes, although some new ministries have been formed and much of the responsibility for the actual conduct of industrial and trading activities is being placed in the hands of quasi-Government boards, the size of the major Departments of State has of necessity much increased. The danger is that these may have become too large and cumbrous to work rapidly and efficiently as single administrative units. Redistribution of functions between existing departments might not, indeed, effect any striking economy in man-power; but a reconsideration of the whole pattern of the Government machine in the light of modern conditions might well suggest a reorganisation that would increase the rapidity and efficiency with which the ever-growing volume of work is discharged. Even if this did not reduce staff, it might obviate further increases and in that way prove true economy.

Nor is this all. A pattern has to be worked out by which the new national boards and other like public corporations which have responsibilities to the State can be incorporated in, or satisfactorily linked to, the administrative machine. Neither in man-power nor in finance can efficiency be secured unless the problem is viewed as a whole, and the task must be attempted by some body equipped for the purpose. The Civil Service has proved itself to be an adaptable organisation, and this valuable characteristic must be preserved in any new alignments.

A review at the highest level during the interval before the planned reviews by 'Organisation and Methods' staffs can be put in operation is suggested as advantageous by the Select Committee. It might well indicate the need for substantial readjustments, and these may affect organisation at lower levels. This is the real reason why the Select Committee is so firm in its view that there must be something much more than the extension of 'Organisation and Methods' work as seen in the past. There must be no more tinkering with the problem, but a thorough and careful scrutiny of the government machine as a task demanding the highest priority among the many demanding attention.

Strong support for this view is to be found in the report from the Fabian Society's Committee, in Mr L. S. Amery's recent book "Thoughts on the Constitution" and in a recent article by Lord Samuel

The latter, in suggesting a Cabinet of ten with a tentative grouping of departmental Ministers in five groups, urges that the time is ripe for a fundamental reform. Recent changes, he holds, have made little difference to the old system, and he suggests that by conferring wide powers on each of these groups, the chairman of each remaining responsible to the Cabinet for its proceedings, with the right to reserve for Cabinet decision matters of general concern or likely to give rise to controversy, or where there had been a serious difference of opinion, the groups might develop distinct individualities while preserving the elasticity which is so excellent a feature of the British constitution.

The Fabian Society's Committee covers a wider field, including within its survey besides questions of organisation those of Parliamentary and financial control as well as control of personnel, but is rarely so fundamental as the Select Committee. Its recommendations on 'Organisation and Methods' do not go much beyond the tinkering which the Select Committee deprecates. It suggests, for example, an Organisation and Methods Committee with qualifications to work out the best office procedure and with powers to impose it on all Departments, but it views organisation and efficiency here rather from the mechanical point of view. Even although it recognizes that the proper functioning of public boards controlling nationalized industries demands freedom and flexibility of action, and that control should not extend beyond matters of policy, it gives little clear guidance as to how such bodies are to be related effectively to the national administration. It recommends that public boards should be linked to the parent departments by small policy-forming bodies in the latter, while unnationalized industry should be guided by controls set up and disbanded as occasion requires on the lines of war-time experience.

While recognizing that for many problems, particularly short-term ones, inter-departmental committees provide the only means of handling problems affecting many departments, the Fabian Committee advocates the extension to the civil sphere of the Joint Staff Committee system, particularly in such fields as central economic planning, building and the supply of fuel and power. It visualizes a standing high-level committee of the permanent heads or appropriate senior officials of departments which are constantly engaged upon some joint activity, and under the general direction of a ministerial body, analogous to the Defence Committee. There should be in each department concerned a central planning organisation, and the Joint Staff Committee should consist of members of the departmental planning organisation, but detached for joint work, and the planning staff should be responsible both for making the plans and for seeing them executed. These planning staffs should be served by a central secretariat—part of the Cabinet secretariat—a vital responsibility of such a secretariat being interpretation.

The Fabian Society's Committee is under no illusions as to the effect of these recommendations in increasing the demand for senior Civil servants, and one of its recommendations is for the immediate admission to the administrative class of a further hundred recruits between the ages of thirty and forty-five. It is much less realistic than the Select Committee, or indeed than a group of Conservatives which put forward proposals for constitutional reform last year, in regard to what is possible with the limited resources of trained man-power in Britain.

There are sensible recommendations regarding leave, entertainment allowances, and amenities for senior officials, but the most interesting feature of this section of the report is the discussion of the relation of the administrative class to the professional, scientific and technical classes. It concludes that civil departments still too often ignore the help which scientific workers could give them on broad questions of policy as well as on technical matters, while the scientific specialists often make little effort to brief administrators properly on technical questions; there is the same lack of co-operation between the administrative class and the professionals. The two essential problems in developing satisfactory relations are to ensure that adequate use is made of specialists both in technical matters and in matters of broader policy, and in preventing the experts from seeing questions exclusively through technical spectacles.

Specific recommendations are on the familiar lines of transfer from the scientific and professional to the administrative class being facilitated, the improvement of pay and status of the former relative to latter, and encouraging mobility of scientific men and professional workers between the Civil Service and universities, industry and other outside employment. Beyond this it is suggested that departments should devise methods of keeping their scientific men and other professional workers informed, and consulting them at an early stage. It is also believed that there is scope for the new technique of operational research in civil departments, and that it could be used in public corporations to measure the value and efficiency of services to the public which can no longer be evaluated in terms of profits to the shareholders.

The Fabian Society's Committee is here on more debatable ground, and the issues are by no means clearly thought out; nor does the report show any clear conception of what is understood by operational research. Fundamentally, it is no more than scientific management properly understood, and from one point of view the use of the term 'research' is perhaps unfortunate and a misnomer. It is implicit in the suggestion, however, that the civil departments are not making sufficient use of the experts at their disposal; and as was brought out in the discussion at Dundee, notably in a contribution by Sir Robert Watson-Watt, operational research is here understood as a renewed attempt to solve the problem of the right relations of the administrator and the expert and the effective use of knowledge in the solution of social and economic problems.

Many of the suggestions put forward by Mr. Amery in his book referred to above are parallel with those made in the reports already noted. By reform and example at the top, he hopes to secure a real co-ordination of the work of departments in the light of coherent policies thought out beforehand, and to eliminate the extemporization and weak compromises which so often result from the attempt to reconcile conflicting departmental policies as and when a problem has obtruded itself on the attention of an overworked Cabinet. Incidentally, while Mr. Amery appreciates the need to encourage the creative and constructive side of the work of the Civil Service, he recognizes that departments have not been so lacking in initiative and creative thought as is sometimes suggested. He is severest on the Treasury, and insists particularly on the need for co-ordination here, as does the Fabian Society's report. That constructive criticism from such varied quarters should issue in such similar proposals should not be overlooked by those who, independent of party politics, are concerned to preserve our great heritage of freedom and adapt it to the needs of the present, having regard both to the new burdens and tasks of Government and to the dangers inherent in the neglect to keep the spirit rather than the letter of the constitution. It is to such criticism that we must look in approaching the general task of increasing the efficiency while decreasing the cost of government; by this means proposals for re-organisation may be forthcoming which will enable Government from the Cabinet downwards to cope effectively with the tasks which face it to-day.

PEOPLES OF THE INDIAN ARCHIPELAGO

The Peoples of Malaysia

By Fay-Cooper Cole. Pp. xiv+354+37 plates. (New York: D. Van Nostrand Co., Inc.; London: Macmillan and Co., Ltd., 1945.) 22*s*. net.

PROF. COLE has aimed at giving, in a comparatively small volume, a conspectus of the extremely varied peoples of Malay affinities, at every stage of culture from that of the primitive food collector of Malayan jungles to the civilized inhabitant of Manilla or Batavia, who inhabit the Indian archipelago. The author postulates an underlying unity of culture multifariously and unevenly affected by various intrusive elements, and accounts for it convincingly by pointing out the way in which the courses of the great rivers of south-east Asia afford a number of extremely divergent outlets to the sea from the comparatively confined area of the sources of the Brahmaputra, Salween, Mekong and Yangtze. In the prolonged and diverse courses of their journeys to the islands, the various branches of the mongoloid stock from which the Malays spring have been subjected to very varied influences, and have received yet more and stronger ones after reaching their island homes. The great diversity that has resulted from this is illustrated by a series of accounts of different tribes chosen from various grades of culture and including tribes of Australoid and of negrito affinities which seem to have preceded the Malayan elements. These accounts are inevitably generalized, and are not all based on personal observation and knowledge, though the author's personal experience of the Indian Archipelago is obviously wide.

In such an account it is almost inevitable that there should be some inaccuracies and occasional dubieties, and while they detract little from the value of this admirable general account of the Malayan peoples, it is probably worth while directing attention to certain of them. Thus the author's general judgment on the problem of negrito variations is obviously sound, but he is very much out of date in putting the total of the Andamanese at 2,000. The number was a little less than that in 1901, and there were only 460 left in 1931. In the Census Report of 1941, the Andamanese do not seem to be mentioned at all. Prof. Cole suggests (p. 89) that the pygmies of Malaysia are unable to swim; but I have seen Andamanese swimming round and under a harpooned but very active dugong some 9 ft. long to rope its flukes to its sides by slipping nooses over its head. The Jakun are mentioned as using a blowgun "artificially bored as in Borneo". It should be made clear that they do not make it themselves; it has always been imported for them from Borneo.

Prof. Cole suggests that the Punans of central Borneo do not exist as a distinct people, but are merely parties of temporary nomads who have been mistaken for such. In view of the circumstantial and detailed accounts of Punans both by Haddon, and by Hose, who lived some twenty-five years in Sarawak, this suggestion seems almost frivolous, particularly in view of Prof. Cole's own statement as to want of knowledge of central Borneo. The suggestion (p. 211) that the long house is "a development from the widespread unit dwelling" may conceivably hold good for the Tinguian, but in many cases it is more likely that the development has been the other way, and that the long house has devolved into a narrow street of separate houses with the bachelors' communal house surviving as a separate building at one end. Indeed, intermediate stages in such a development have been observed in New Guinea.

The effect of contacts with Malaysia from India have perhaps not been entirely understood, for they must have started at a considerably earlier date than the development of Brahmanism; and on the other hand, there are indications of some very early development and dispersion of culture from a centre in the archipelago which possibly carried items of culture like househorns of the Menangkabau far afield to Assam and Madagascar. The ancient bronze 'kettledrums' of the Karens, of Siam, and of Cochin China have likewise been ascribed by some authorities to an island source, such as may have also been responsible for the great monolithic burial urns of Cochin China, Sumatra and Assam. Had the author cast his net wider than Malaysia, he would have found an even closer correspondence of cultural features widely spread in south-east Asia (and beyond it) than he himself suggests.

It remains to add that Prof. Cole criticizes severely the nature and effects of British Colonial policy in Malaya, contrasting it, much to its disadvantage, with the policy of American administrators and Roman Catholic missionaries. It would, we think, be possible to present a very different picture of the results of American policy in the Philippines without any greater departure from objectivity. There are several misprints, and the illustrations are poorer than we have learned to expect from American publications of this class.

J. H. HUTTON

SCIENCE AND PEACE

Science, Liberty and Peace

By Aldous Huxley. Pp. 64. (London: Chatto and Windus, 1947.) 3*s*. 6*d*. net.

WITHIN the limits of the present slender volume it would be manifestly absurd to expect a profound contribution to thought on the great issues named in its title. Nevertheless, while displaying once more the intellectual reaction against nineteenth-century faith in the capacity of science to improve human society which characterizes his philosophical writings, Mr. Huxley sets forth clearly the inter-relations between science, liberty and peace. The two essays of which the book consists make no claims to originality of thought, and it is easy to recognize the influence on Mr. Huxley's thinking of A. N. Whitehead, Louis Mumford, Karl Mannheim, E. H. Carr, Lord Lindsay and others. The slenderness of the volume should not, however, have prevented the inclusion of at least some references which would help the reader who is interested to explore further sources on which, consciously or subconsciously, Mr. Huxley has drawn.

Mr. Huxley concludes his book by commending Dr. Gene Weltfist's suggestion in the *Scientific Monthly* (September 1945) that technicians and men of science should take a professional oath similar to that of Hippocrates, pledging themselves to use their knowledge for the good of humanity and against the destructive forces of the world, and to work for such common ends with their fellow scientific workers of whatever nation, creed or colour, and he is presumably addressing himself primarily to the man of science and technician. It is not otherwise easy to discover either his purpose or the type of reader for whom the book is intended. For the general reader the argument is scarcely simplified enough. His main point regarding the small community, with the suggestion that science will assist us to solve the problem of power by devising methods to enable small communities to be self-sufficient in such matters as food supply and power, which is the essential contribution of the book, might well have been made clearer by using the Tennessee Valley Authority as illustration in greater detail. Had he done so he could scarcely have made the assumption that the 'integration' of a scientific and political approach involves the imposition of something from above and not the organic union and harmony of functions which McCurdy had in mind in discussing the problems of social organisation. Mr. Huxley criticizes rather obliquely the theme Col. Urwick developed in an address on "Compromise and Integration"; but it is difficult to believe that he has read either that or Lilienthal on the Tennessee Valley Authority.

Like so many others Mr. Huxley is better at diagnosis than prescription. He stresses rightly the immense power which science and technology have put into the hands of those who control the modern State, and he infers that if resistance is to be offered by the many to the few it must be in a field in which technological superiority does not count. But his defence of passive resistance is as naïve as his argument that it has never been tried is historically unsound. Again, while he recognizes the economic and social security which technological progress has brought, and although he pleads for the help of religion and for a moral basis for world order, he does not show the same awareness of the moral disintegration which Duckheim stressed or of the power of a moral tradition as the only effective brake on misgovernment.

These lapses and omissions detract from what is none the less an interesting and suggestive, if scarcely persuasive, book. Mr. Huxley, in truth, is too faint-hearted an advocate. He can see through many of the illusions of his time and, indeed, over-simplifies the issues. Even his argument for decentralization and development of the autonomous groups is advanced without much clear confidence that the man of science and technician will heed the summons to co-operate. Mr. Huxley sees clearly enough the implications for individual freedom of the concentration of power in ever fewer hands; but the argument for decentralization could have been strengthened had he analysed more fully or philosophically the idea of freedom. Recognizing that science and technology have changed the basic postulates of thought and that the scientific picture of the world is inadequate because science only deals with certain aspects of experience in certain contexts, he urges the study of philosophy by the man of science and technician, and that ministers of religion should teach a new doctrine of the Final End of Man rather more nebulous than that according to the Shorter Catechism.

If Mr. Huxley's remedies seem to be over-simple they are not necessarily invalid so far as they go, and this plea for a re-statement of the Emersonian doctrine of self-reliance with particular reference to the techniques available for achieving independence within a localized, co-operative community is pressed as the means of securing the abolition or elimination of war, in spite of the opposition from Governments which anything like a popular movement would encounter. Mr. Huxley suggests that as individuals or in organised groups scientific workers can help in three ways. First, and negatively, they should consider the problem of right livelihood in its relation to their own contemporary activities, and they should seek answers to these questions on the level of their international organisations. Next, he suggests tentatively the exploration in a wider field of the plans for an international inspectorate already outlined in regard to the atomic bomb and the pooling of all scientific discoveries considered by competent experts to be even potentially dangerous to mankind.

Scepticism as to the value of such safeguards will not be diminished either by the publication of the new Russian law classifying as State secrets research and experimental work in all branches of science and technology or by the exclusion of atomic energy from the discussions at the recent International Congress of Pure and Applied Chemistry. Mr. Huxley looks more hopefully to action initiated in the scientific field and ending in the political. The planning of scientific activity for predetermined political, social and economic ends must begin where the results of disinterested research—which itself cannot, he observes, be planned more than to the extent of subsidizing inquiry into neglected branches of knowledge—are applied to the solution of practical problems. Individually and through their professional organisations men of science and technicians could, he maintains, do much to direct planning towards humane and reasonable ends. Further, he thinks it possible, if not essential, for technicians and men of science to adopt a professional policy, consciously and deliberately designed to serve fundamental human needs and to forward the causes of peace and personal liberty.

That, indeed, might fairly be described as the purpose of the Atomic Scientists' Association; but Mr. Huxley insists that only an international organisation of men of science could work out such a policy in detail. Tentatively he indicates what such a policy would include: a world-wide campaign for greater food production, including regional self-sufficiency in food production, and, scarcely less important, self-sufficiency in power for industry, agriculture and transport. On the technical implications of such a policy he does not enlarge, although he notes that the storage as well as the production of power has to be considered, but expresses the opinion that atomic energy is, and for a long time is likely to remain, a source of industrial power that is politically and humanly speaking in the highest degree undesirable.

Mr. Huxley has ideas and suggestions that merit discussion, but whether this book of itself will stimulate such debate is doubtful. It lacks the conviction that compels to action. The critic who shatters illusions remains too much the sceptic to be the prophet or apostle of a crusade to overthrow the tyranny of which he complains and build a new world in which science will be free and used for peace.

R. BRIGHTMAN

PALÆOBOTANY FOR EVERYMAN

Ancient Plants and the World they Lived In

By Assoc. Prof. Henry N. Andrews, Jr. Pp. ix+279. (Ithaca, N.Y.: Comstock Publishing Co., Inc.; London: Constable and Co., Ltd., 1947.) 25*s*. net.

THIS book is an attempt, and a very successful attempt, to convey to the general reader an idea of the vegetation of the earth in ages long past and the indications it may give of the climates of those times. From a study of their fossil remains so many details are now known about extinct plants that it is no easy task to give a convincing description of what the vegetation was like without becoming involved in highly technical descriptions of many individual plants. The author has shown admirable discrimination in his choice of examples, and gives a clear picture of the kinds of plants which dominated the vegetation at different periods in the past. He has skilfully steered a compromise course between the Scylla of technical jargon and the Charybdis of terminological inexactitude, and the book is written in a very readable and racy style.

The author is evidently an enthusiastic collector of fossil plants and will certainly stimulate others to take an interest in them. The study of fossil plants, palæobotany, has been greatly neglected in most countries, and in very few schools of geology is any instruction in palæobotany given. Such a book as this will help to show the geologist in how many different directions the study of plant fossils leads to a widening of our knowledge of the past history and climate of the earth.

The book is admirably printed and illustrated. One very impressive illustration is of an open-cast working at Wyodak, in Wyoming, in which there is a 90-ft. seam of coal. Other illustrations include excellent views of the Yorkshire coast and other places in Britain and North America which are notable for the fossil plants which have been found there. The author gives a clear idea of the appearance and nature of fossil plants and where they may be discovered. He explains the manner in which coal has formed and some of the methods used in investigating its structure. For those who have had no botanical education he provides a useful little appendix on the structure of living plants.

The author in the next edition should provide fuller descriptions of the illustrations and make greater use of letters with guide lines. In some illustrations (for example, Fig. 100) there is nothing to indicate the positions of the parts mentioned in the description, and the non-specialist reader will be at a loss to understand what the figure represents.

JOHN WALTON

APPEAL OF MUSEUMS

Native Animals of New Zealand

(Auckland Museum Handbook of Zoology.) By A. W. B. Powell. Pp. 96. (Auckland: Auckland Institute and Museum, 1947.) N.p.

THE educational function of museums has been much discussed in Great Britain during the last decade but, with notable exceptions, the attractiveness of their exhibitions has not been great enough to draw in and hold many, apart from those who already have some interest in the museum contents. There are many reasons for this lack of appeal, one of them being lack of imagination on the part of museum authorities and a strange unfamiliarity with the methods by which the general public should be encouraged to compel its interest. For these and other reasons this book should be carefully studied by museum authorities; similar publications would do much to increase the attractiveness of their own institutions.

While the work primarily is meant to be a guide book to the New Zealand natural history exhibits in the Auckland Museum, the author has avoided the easy temptation of allowing it to become a mere catalogue. The book is, in fact, a popular treatise on the native fauna, providing simple descriptions, recognizable illustrations and brief but essential information concerning the better known and more interesting New Zealand animals. For ease of recognition the figures have been drawn from actual specimens and, in order to help the amateur naturalist in recognizing animals in their natural surroundings, the text is mainly concerned with external appearances, habitat and behaviour. In keeping with evolutionary theory the animals have been arranged approximately in their systematic order although, since the handbook is mainly concerned with sight identification, all microscopic animals are omitted.

A cursory glance at the 411 illustrations shows some of the peculiarities of the New Zealand fauna. The absence of land mammals is at once conspicuous, and the inquisitive reader finds a reason for this expressed in clear and interesting language. The comparatively large number of flightless birds is also readily apparent and is accompanied by a careful account of each species. Animals like the tuatara (*Sphenodon punctatus*) and *Peripatus* are given special mention, as are the remarkable summer migrations of birds like the godwit and cuckoos. Mr. Powell must be thanked for producing a work which will not only add to the attractiveness of his own museum but which should also put ideas into the heads of discriminating museum workers elsewhere.

T. H. HAWKINS

V. Rosický

By F. Slavík. Pp. 24. (Prague: Czech Academy of Science and Arts, 1946.) 12 crowns.

PROF. VOJTĚCH ROSICKÝ was a distinguished Czech mineralogist whose scientific work was cut short by his execution at Mauthausen concentration camp in February 1942, in his sixty-second year. His father, who died in 1919, had been a naturalist and writer on scientific subjects, and young Rosický grew up in an atmosphere of excursions to forest and mountains in search of specimens. He began as science master at a Prague *Gymnasium*, for which he wrote a "Chemie a Mineralogie". Later he went to Munich as Groth's assistant; eventually he returned to Prague and, in 1920, became professor of mineralogy at the new University of Brno. His publications—mostly in Czech although some appeared in the *Zeitschrift für Krystallographie* and in French journals—dealt with crystallographic methods, the physical properties and measurements of crystals and the relation between physical properties and water content. He described, often in great detail, a variety of minerals from Europe, South Africa and South America, including a joint work with V. M. Goldschmidt on a topaz from Minas Geraes. Rosický also made some petrographical studies and wrote several text-books, including a lengthy "Krystalografie", one volume of which appeared in 1929 (with more than five hundred illustrations). The second half he left in manuscript, which is now being prepared for publication by Dr. J. Sekanin, with whom he was conducting X-ray crystallographic researches until the University was closed in 1939.

Prof. Slavík, himself a mineralogist well known in Britain, has written this short biography in appreciation of his countryman's contributions to mineralogy.

J. G. F. D.

L'Organisme en lutte contre les microbes

Par André Boivin et Albert Delaunay. (L'Avenir de la science, 24). Pp. 425 + 15 plates. (Paris: Libr. Gallimard, 1947.) 320 francs.

THIS latest addition to Gallimard's popular science series is of the same high standard as its predecessors, some of which have already been reviewed in *Nature*. Without diminution of scientific value the subject has been reduced to terms which can be understood by non-medical readers, but the book would be useful and easy reading for medical students preparing for examination.

The first part describes bacteria and viruses and the nature and evolution of infectious diseases. The second part describes the body's defences against invading organisms; the role of the phagocytes, antigens and antibodies. Part three deals with prevention and treatment of infectious diseases. Recent advances in chemotherapy and antibiotics are included. There is a detailed list of contents, but, unfortunately, no proper index.

The Annual Register

A Review of Public Events at Home and Abroad for the Year 1946. Edited by H. T. Montague Bell. Pp. xii + 504. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1947.) 42*s*. net.

THIS valuable volume makes its one hundred and eighty-eighth appearance as a full and objective record of the year's events. It is under new editorship, Dr. Epstein having died during the past year, but retains its well-established plan and scope. British history is told in four sections, followed by the history of the Commonwealth and Empire, with the troubled story of India and Burma. Then an equal share is devoted to foreign history, including the United Nations Organisation. Here the four Great Powers have the major part, but naturally the States of the troubled eastern side of Europe receive considerable attention. The latter part of the book is devoted to the usual chronicle of the year, obituaries and surveys of literature, art, science and finance. The public documents printed in full are the Anglo-Siamese agreement, the Yalta agreement and the White Paper on India.

Outlines of the Geography, Life and Customs of Newfoundland-Labrador (the Eastern Part of the Labrador Peninsula)

Based upon Observations made during the Finland-Labrador Expedition in 1937, and the Tanner Labrador Expedition in 1939, and upon Information available in the Literature and Cartography. By Prof. V. Tanner. Vol. 1. Pp. ii + 436. Vol. 2. Pp. ii + 437–909. (Cambridge: At the University Press, 1947.) 2 vols., 50*s*. net.

LABRADOR has a considerable literature of its own, as the full bibliography in this volume shows, but it is mainly concerned with the coastal regions which constituted that part of Labrador under the rule of Newfoundland. In 1927 the Privy Council brought within Newfoundland-Labrador the Atlantic drainage, leaving the remainder to Canada. Thus an area of about 100,000 square miles is a dependency of the former dominion of Newfoundland. The two large and beautifully illustrated volumes of this work, originally printed in Finland in *Acta Geographica*, do not claim to present a completely co-ordinated geography of Labrador. They contain rather the raw materials of such a work, from which much can be deduced. But the work is admittedly incomplete, partly because of the vastness of the area and partly because the second expedition of Prof. Tanner in 1939 was interrupted by the outbreak of war. It is, however, of interest to note that Prof. Tanner, versed in the conditions of Finland, sees no reason why much of Labrador should not eventually be colonized, even if it cannot become a self-supporting agricultural country.

I Know an Island

By R. M. Lockley. (Harrap's Country-Lovers Library.) Pp. 243. (London: George G. Harrap and Co., Ltd., 1947.) 8*s*. 6*d*. net.

ISLANDS where the sea-birds come to breed have a peculiar fascination, an appeal felt early and with great force by Mr. R. M. Lockley. He was not happy until he had acquired one, and even then he was not satisfied. Skokholm, that sanctuary of Manx shearwaters, storm petrels, puffins, etc., off the Pembrokeshire coast of Wales, only whetted his appetite for islands. In his book "I Know an Island", first published in 1938 and now reprinted, he tells of his own island of Skokholm, the neighbouring islands of Skomer, Grassholm and Ramsey and their inhabitants, both winged and furred, before going on to islands farther afield. The Blaskets off the Irish coast, Heligoland, Fair Isle, the Faeroes and the Westermann Islands are among those visited and interestingly described, with special reference to ornithological matters. For example, Mr. Lockley searched far for Leach's fork-tailed petrel, to find it at last on Sudurey in the Westmann Islands.

F. PITT

LOW-TEMPERATURE PHYSICS IN NORTH AMERICA

By Prof. J. F. ALLEN
University of St. Andrews

During the past summer, an opportunity was taken to visit the principal laboratories in the United States and Canada which are engaged in low-temperature research, with the exception of the Naval Research Laboratory in Washington, the laboratory directed by Giauque at Berkeley and that planned by Long at Chicago.

Prior to the War, comparatively little interest was shown in America in cryogenic research, with the notable exceptions of the Chemical Laboratory at Berkeley and the McLennan Laboratory at Toronto, and on the whole what interest there was lay in the field of chemical thermodynamics. To-day, although the position is changing rapidly, and again with the possible exception of Berkeley, there are still no cryogenic laboratories in America such as we know them on the eastern side of the Atlantic, equipped to carry out physical research in all the principal low-temperature fields, of which the three most important are superconductivity, paramagnetics and the properties of liquid helium. But the position is changing very rapidly indeed. There is in America a growing realization of the importance of low-temperature physics, and a very rapid growth in the number of laboratories using liquid helium. There are roughly a dozen such at the present time, and another dozen will probably be added within the next year.

This extremely rapid growth has been made possible largely by the new liquefier designed by Collins of the Massachusetts Institute of Technology. This liquefier can be considered as deriving from the one designed by Kapitza, but it is carried a stage further in that all the cooling is obtained by the principle of external work, and no other refrigerant, such as liquid air or hydrogen, is required. There are in the Collins machine two expansion cylinders and pistons, one operating at roughly the temperature of liquid air and the other at the temperature of liquid hydrogen. There is essentially only one heat exchanger, which is tapped off at two points to feed the cylinders, and at the bottom end is the Joule–Thomson valve where liquefaction is performed. The whole apparatus is extremely simple and elegant. It has been designed for something like mass production and can now be purchased, more or less 'over the counter', from the Arthur D. Little Corporation of Cambridge, Mass., for 18,000 dollars (August 1947 price). For this, it was learned, one obtains the complete plant, including gas holder, garage-type compressor, helium purifier and auxiliary vacuum pump, installed and ready to run. The whole assembly, less the gas holder and compressor, is fitted into a rectangular box about 5 ft. 6 in. in height, 3 ft. 6 in. wide and 3 ft. deep. The machine takes about four hours to cool to helium temperature and will then produce somewhat less than two litres of liquid helium an hour. It is not limited to helium production, but by its nature it will liquefy any gas. If, however, other liquid gases are wanted, it is possible to use helium as the working substance and liquefy other gases by contact, and it can thus provide a particularly useful and safe way of making liquid hydrogen.

The Collins liquefier, being compact, self-contained and simple to operate, is an admirable liquefier for the laboratory in which it is desired simply to extend existing researches or measurements to the helium range of temperatures. Also, it is designed expressly for the purpose of having experimental apparatus installed directly in the liquefier, since there is an opening in the top some 5 in. in diameter and a clear space beneath at least as large leading directly to the liquid helium bath. These reasons, together with the fact that the U.S. Navy makes extremely generous provisions for physical research in America, produce a tendency in the more ambitious laboratories to have a separate Collins machine for each experiment. Both the Naval Research Laboratory in Washington and the Massachusetts Institute of Technology have two liquefiers, and it was understood that both laboratories were planning to acquire additional ones.

It is, of course, easily possible to decant the liquid helium from the Collins machine; but that requires additional equipment such as Dewar vessels and liquid air for the thermal shielding, which are not always available. Hence the liquefier tends to be used for experiments which do not require either visual observation through the apparatus or the presence of magnetic fields. Furthermore, due to the comparatively poor shielding of the liquid in the liquefier from room-temperature radiation, it is not easy to reach a very low temperature by reducing the vapour pressure of the liquid.

Two other helium liquefiers which are being constructed are of interest. In Toronto an attempt is being made to use a turbine as a means of extracting work, and in the Ohio State University at Columbus a very large output of liquid helium is expected from a Joule–Thomson liquefier using only liquid hydrogen, of which there is a plentiful supply, as a refrigerant. A feature of the laboratory at Columbus was the immense size of the cryostats. The glass Dewar flasks, made on the premises, were four to five feet in height and six to eight inches in diameter.

Several other laboratories have small Linde or Simon single-expansion liquefiers, and at Yale there is a more or less exact replica of the Kapitza liquefier in the Royal Society Mond Laboratory at Cambridge.

Of the low-temperature research which is going on there is, of course, a considerable amount of accurate calorimetry devoted to chemical thermodynamics. On the physical side, the most important subjects at the moment are the separation and properties of the isotope helium 3, and the behaviour of superconductors under the action of very high-frequency currents, using radar techniques.

The phenomenon of the disturbance of superconductivity by high-frequency fields was first observed by H. London in Bristol before the War, and the effect of using 25-cm. waves in superconductors and in normal metals has been examined in detail by Pippard in Cambridge since the War. At the Massachusetts Institute of Technology, under Slater, and at the Naval Research Laboratory in Washington, the problem is under investigation using 1·25-cm. waves. The superconductors which have been investigated so far are tin and lead, and the methods which are employed are slightly different in the two laboratories. At the Massachusetts Institute of Technology, the waves, conducted in by wave-guide, are reflected at the end of the guide by a superconducting element which is in the form of a cavity of the dimensions of the guide, across which a thin perforated superconducting membrane is stretched. At the Naval Research Laboratory the waves are conducted down to a superconducting drum-shaped cavity and the energy absorption is measured by the determination of the ringing time of the cavity.

Slater has obtained results similar to those of Pippard, but the destruction of superconductivity was more complete, as was to be expected from the higher frequency which has been used. He is also studying the so-called anomalous skin resistance of normal metals at low temperatures.

The work on the properties of the rare isotope helium 3, which has a normal concentration of about one part in 10^6 of helium 4, has been done by Daunt at Columbus and Lane at Yale with the mass-spectrographic collaboration of Nier at Minnesota. Lane has found that the vapour above the surface of liquid helium has a higher concentration of helium 3 than has the liquid, which indicates that if pure helium 3 can exist as a liquid, then its normal boiling point will be lower than that of helium 4. Daunt has further shown that helium 3 does not participate in the surface transfer of liquid helium II, which means that helium 3 is not in the superfluid state, at least at temperatures above 1·5° K., whereas helium II loses its superfluidity at 2·19° K. The fact that helium 3 is not superfluid offers the possibility of considerable enrichment of the helium 3 content by 'straining' helium II through a porous plug—called by the Americans a 'superleak'. It was rumoured in America that there exists a small quantity, of the order of 1 c.c., of pure helium 3, but not produced by the above means.

Other research on helium II at Yale consisted in investigations on second sound, in which, among other things, an attempt was being made to convert ordinary sound into second sound by passage of the waves through a porous membrane. At the Massachusetts Institute of Technology, Squire has made an investigation of the attenuation of ordinary sound, of ultra-sonic frequency, in liquid helium. Here the most important feature is the fact that the absorption rises to an indefinitely high maximum at the λ-point.

Among other researches in progress, Andrews at Johns Hopkins is investigating the phenomenon which he has discovered of the 'rectifying' property of the transition region in superconducting niobium carbide, which occurs in the neighbourhood of 15° K. One of the odd features of this phenomenon is that at a suitable temperature and with a suitable biasing current through it, the carbide specimen can pick up the local radio station with the aid of an amplifier and loud-speaker.

Boorse, at Columbia, is also planning to investigate niobium carbide and nitride, but from the magnetic point of view. He has a Simon expansion liquefier. Brickwedde, of the U.S. Bureau of Standards, also has a Simon liquefier of about one quartre-litre capacity. Aside from his calorimetric work, he is investigating the so-called 'overshoot' phenomenon in superconductivity which he discovered some years before the War. Some criticism has been expressed of the reality of this phenomenon, which involves very high measuring currents, owing to the possibility of local temperature fluctuations, and he is planning to repeat the investigations on indium, which has a transition temperature in the helium II region, where temperature fluctuations are much more difficult to produce.

None of the cryogenic laboratories visited are at present engaged on magnetic cooling experiments, although one or two of them intend to commence such work within the next year or two.

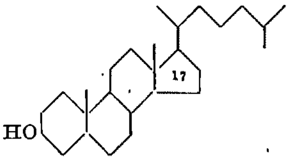
TOWARDS THE SYNTHESIS OF CHOLESTEROL

By Dr. J. W. CORNFORTH and Sir ROBERT ROBINSON, F.R.S.

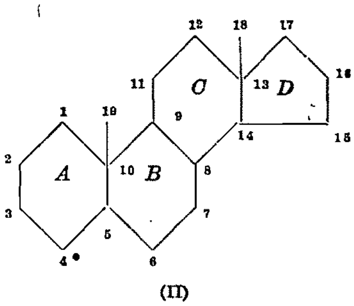
National Institute for Medical Research and Dyson Perrins Laboratory, University of Oxford

No development of organic chemistry or of biochemistry has unfolded in a more dramatic manner in recent years than that concerned with the nature and functions of the steroids, the bile acids, and the related vitamins and hormones.

The typical compounds, cholesterol and cholic acid, excited the curiosity of Windaus and of Wieland because of their complex and obviously interesting molecular constitution; and the brilliant researches of these pioneers were supplemented by contributions from many other laboratories, especially when discovery of the biological significance of the group came to light. The chemical puzzle was transformed into a problem of vital urgency for physiology and medicine. The outcome has been that the structures of the chief members of the rapidly expanding family of substances are known in so far as that is possible without the final confirmation of successful synthesis. This latter task has been regarded as one of the most difficult that could be undertaken by the organic chemist, for the simple reason that it is far from sufficient to devise a method of constructing a substance corresponding to the formula as written on paper, difficult though that may be in itself. The molecule of dihydrocholesterol (I) contains nine asymmetric carbon atoms, and hence 512 stereoisomeric forms are possible. There is reason to believe that all these should be capable of existence. Even if the side-chain is not present, and position-17 carries a carbonyl group, there are still 128 stereoisomeric modifications. It is a triumph of analysis that a combination of chemical and physical methods, culminating in the X-ray crystallographic studies of cholesteryl iodide[1], has disclosed the stereochemical configuration of the ring-systems (cf. II) in the best-known steroids.



(I)

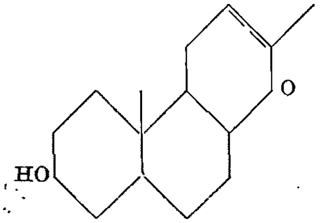


(II)

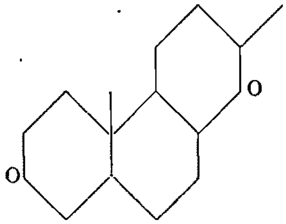
Rings *A* and *B* are fused together in the *cis*-position (coprosterol, cholic acid) or *trans*-position (dihydrocholesterol) in various derivatives, whereas rings *B* and *C* are fused in the *trans*-position in all known cases. For any given orientation of rings *A* and *B*, there are two such *trans*-fusions of *B* and *C*. Expressed in a different way, the configuration of C-9 must be established correctly in relation to C-10; that of C-8 must then be correct in relation to C-9. It is not necessary at this stage to discuss the fusion of rings *C* and *D*.

After a long series of investigations in other directions, we selected a synthetic route which had the useful feature that the stereochemical vagaries were placed under the maximum of control. The ring *A* was added to *B* : *C* in such a way that modification of ring *A* was feasible, while C-9 and C-8 (of II) were not yet asymmetric centres. It was shown at this stage that *cis*-fusion of *A* and *B* had been effected. The asymmetric centres at C-9 and C-8 were then set up, from analogies in *trans*-relation, and a separation of two series achieved in which the relation C-9 : C-10 was in the two possible senses. In this way a tricyclic substance was obtained which was convertible into a derivative of a tricyclic degradation product of desoxycholic acid. We have also completed the transformation of a cholesterol degradation product into the same substance. Thus sixteen carbon atoms have been joined in the space arrangement obtaining in coprostanone (for exactness), and the first synthetical proof of the existence of an angle-methyl (C-19) attached to C-10 has been given.

The Tricyclic Degradation Products. The oxidation of methyl O-diacetyldesoxycholate by means of chromic acid[2] afforded a number of neutral products in small yield. After hydrolysis, Reich[3] showed that one of these is an unsaturated keto-alcohol the constitution (III) of which follows from that of desoxycholic acid. By reduction, followed by oxidation, III gave a saturated diketone (IV).

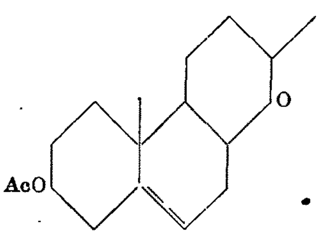


(III)

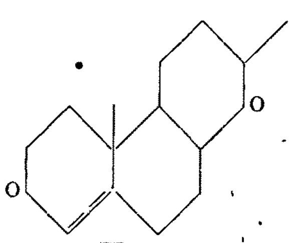


(IV)

Köster and Logemann[4] obtained (V) by suitable treatment of the mother liquors from the oxidation of cholesteryl acetate dibromide, after separation of acetates of dehydroandrosterone and pregnenolone. A small quantity of (V) was kindly supplied by Dr. K. Miescher of the Research Laboratory, Pharmaceutical Department, Ciba Company, Basle. By successive hydrolysis, oxidation (to VI), and reduction (a new stage), it was converted into (IV) (Specimen *A*). Specimen *B* is the Reich diketone (IV), for which we are indebted to Dr. H. Reich and Prof. T. Reichstein. Specimen *C* is the synthetic diketone (IV). We are very grateful to our Swiss colleagues for their generous help.



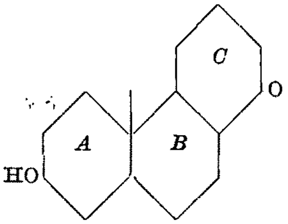
(V)



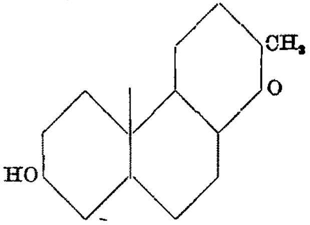
(VI)

The melting points, mixed melting points, and rotatory powers of *A*, *B*, and *C*, showed them to be identical. Dr. D. Crowfoot was able to use single-crystal technique for the examination by X-ray methods and has reported the complete identity of the three specimens. We are greatly obliged to her for such a satisfactory investigation made on the eve of a journey to the United States.

The Method of Synthesis. The preparation of (VII) from 1 : 6-dihydroxynaphthalene has already been described[5]. Considerable modifications and improvements have since been made in the details of the necessary operations, and transformations of the intermediate products have been realized such as to prove that rings *A* and *B* in (VII) are in *cis*-relation.



VII) (*A* and *B*)



(VIII) (*A* and *B*)

Although early specimens of (VII) were homogeneous (*A*-isomeride), it became evident, when larger quantities were available, that two isomerides were produced. These were first recognized after the preparation of the hydrogen succinates, which derivatives still afford the best method of separation. After hydrolysis, the hydroxy-ketones *A* and *B* are obtained in the ratio of about 6 :1. On oxidation they yield diketones *A* and *B*, so that their isomerism is not wholly (and probably even not partly) dependent on the configuration of the *sec*-alcoholic group. It must be connected with the mode of fusion of rings *B* and *C*. But (VII) is an α-decalone and has been subjected to treatment which is known to convert *cis*-α-decalone into the *trans*-isomeride. Hence the hydroxy-ketones (VII), *A* and *B*, probably represent the two possible *trans*-fusions of rings *B* and *C*. The optical resolution of the hydroxy-ketones *A* and *B* was then studied.

In the *A*-series, the crystallization of the *l*-menthoxyacetates was applicable and both enantiomorphs were obtained in a pure condition; m.p. 120·5–121·5°; $[\alpha]_D^{24}$ ± 38·5° (± 2°) in chloroform. In the *B*-series crystallization of the brucine salt of the hydrogen succinate afforded the pure derivative of the *B* (−) hydroxy-ketone. The *B* (+) hydroxy-ketone (VII) could be purified as the hydrogen succinate and was also obtained in a pure condition; hemihydrates, m.p. 113–114°; $[\alpha]_D^{24}$ ± 10° (± 0·5) in chloroform. Only 1·132 gm. of the *B*-isomeride hydrogen succinate was available for this resolution.

For the introduction of a methyl group in the 2-position (phenanthrene numbering), the method of Sen and Mondal[6] was employed; namely, successive formylation, methylation and hydrolysis. The hydroxymethylketones (VIII) were then oxidized to give two pairs of methyl-diketones of the structure (IV).

The methyl-diketones-*A* had m.p. 141–142°, $[\alpha]_D^{25}$ ± 20° (± 2°) in chloroform. The methyl-diketones-*B* had m.p. 116·5–117·5°, $[\alpha]_D^{25}$ ± 25° (± 2°). Reich[3] attributes m.p. 119·5–121° to his specimen *B*, but this melting point was taken on the Kofler-block and corrected (± 2°). Under our conditions the specimen provided had m.p. 116·5–117·5°. The same was true of specimen-*A*, made from the Köster–Logemann keto-acetate. Mixtures of the specimens had the same melting point. A full account of the experiments briefly summarized herein will be published in another place.

Prognosis. The synthesis of the tricyclic degradation product undoubtedly opens the way to a total synthesis of cholesterol and its ramifying derivatives. Referring to (II), the configuration of positions 5, 10, and 9 is secure, and that at 8 is also unlikely to be affected by subsequent changes at 14 and 13. We now propose to add ring *D* in a simple manner and hope to obtain two isomerides dependent on the relation of configuration C-13 to C-9. If that is found possible, the total synthesis becomes a matter of routine and eventually will certainly be accomplished.

PESTS OF STORED FOODS

FOOD AND AGRICULTURE ORGANISATION CONFERENCE

A MEETING of scientific workers concerned with pests of stored food was held in London in the week of August 4. The meeting was opened by Sir John Boyd Orr, director-general of the Food and Agriculture Organisation, who urged the delegates to propose methods which would enable Governments to preserve the 1947 harvest.

The subjects discussed included the appraisal of food losses; the spread of pests throughout the world; specific methods of control of insects and mites, of rodents and of fungi; storage methods; the world supply position of poisons; the dissemination of knowledge; and research needs. The chair was taken throughout by W. McAuley Gracie (United Kingdom), who contributed the opening paper on the economic significance of infestation. Most of the scientific papers were on the control of insects and mites. R. T. Cotton (United States) and H. E. Gray (Canada) presented comprehensive studies on the preservation of cereals from insect attack during storage. J. A. Freeman (United Kingdom) gave an account of world foci of infestation and channels of its dissemination, with suggestions for detection and standards of inspection. Prof. R. Mayné (Belgium) spoke on conditions and control methods in his country; R. Attia (Egypt) on conditions in both modern and ancient Egypt; K. R. Söntakay and H. S. Pruthi (India) on traditional Indian methods of storage and on modern rat-proof construction; Prof. P. Vayssière (France) on the principle of air-tight ensilage. A detailed account of the methods of grain drying was given by T. A. Oxley (United Kingdom).

On rodents, E. R. Kalmbach (United States) sent a paper on rodent control in the United States, and S. A. Barnett (United Kingdom) gave an account of the principles of rodent control based on the work carried out in Britain during the War.

The secretary of the Conference, S. S. Easter (Food and Agriculture Organisation), gave a report on estimates of losses due to infestation of stored foods. It was agreed that it is quite impracticable to give any reliable estimate of losses for any large area. Various estimates were quoted, including the statement that 10 per cent of the world's stored food is destroyed by pests. It was, however, considered that all such estimates are likely to be below the mark, owing to the high proportion of food stored in small lots by peasant farmers and not entering world trade.

The methods of insect control include fumigation, spraying and dusting, as well as preventive measures such as grain-drying and improvement of hygiene and of building construction. The committee on grain-drying urged that a world-wide study of this problem should be made, so that improved methods could be devised for each area. Economic as well as technical problems are involved, since drying grain reduces its weight; and if the grain is sold by weight, this may entail loss to the producer.

For rodents, the sub-committee urged the general adoption of the method of poisoning, preceded by prebaiting with plain bait. This method, based on research at Oxford during the War, can ensure almost complete clearance in most areas if it is rigorously applied. Again, the preventive measures of improvement of hygiene and buildings were recommended; but it was pointed out that in many areas they can be part only of a long-term project.

Inevitably, the meeting became involved in the discussion of wider problems. There was complete agreement that every country needs a pest control organisation with a staff of trained persons, including scientific investigators and operators. International agreement on certain aspects of pest control organisations is also required. This is exemplified by occurrence of the transfer of pests from one country to another by ship. The transport of rats is an old story, and the damage has already been done. But the transport of some serious insect pests is a recent affair and is still going on. For example, the mill moth (*Ephestia kühniella*) was first noticed as a pest of mills in Germany in 1877; by about 1900 it had a world-wide distribution, and it now costs the British milling industry alone some thousands of pounds a year for cleaning and fumigation, apart from the losses due to infestation of flour and offals. Similarly, the spider beetle (*Ptinus tectus*) was unknown in England before 1892. By 1916 it had spread all over the country and is now to be found in every warehouse in Britain. Its original home was probably Tasmania. Neither of these species is to-day often intercepted on imports; but, had an adequate quarantine service been in operation in the late nineteenth century, the entry of both might have been prevented. During the past few years the Government organisation has intercepted insects not hitherto recorded in the United Kingdom, and in some instances previously undescribed species. The delegates of other countries, and notably Belgium and France, recorded experiences similar to those in the United Kingdom.

Within each country the need for a pest control organisation raises a number of problems which have a more general application than to pest control alone. Prof. J. W. Munro (United Kingdom) gave a paper on the dissemination of information. He dealt first with the need for improvement in the information services available to scientific workers, and in particular, of abstracting services. This, as always, commanded general support. He then went on to refer to the problem of keeping administrators adequately informed. The extent to which administrators seek, or are given, advice varies greatly in different countries, and at different times in the same country. In times of crisis advice is readily sought, often when it is too late; at other times it may not be sought at all, and if offered, it may be disregarded. The meeting, said Prof. Munro, gave an opportunity of ensuring that scientific opinion was heard in high quarters, and he hoped that the meeting would state the strongest case it could to that end.

Finally, Prof. Munro and many others referred to the need for the education of transporters, warehouse-keepers, millers, wharfingers and the general public. A few countries have done a good deal in this direction, and Denmark gave an example by showing an entertaining film illustrating how bad hygiene and ill-kept buildings encourage infestation. At the other extreme there are the backward countries, mainly in the tropics and sub-tropics. The delegate from Siam gave examples of the formidable problem of educating peasant farmers in pest control. It was, however, pointed out that there is much ignorance to be combated even in the more advanced countries, where it is still common to find farmers and traders who believe in spontaneous generation.

Delegates visited the Ministry of Agriculture and Fisheries Infestation Control Division building, the Pest Infestation Laboratory at Slough, a large-scale grain drying plant, an exhibition of food pests at the British Museum (Natural History) and a number of demonstrations on pest control methods.

The Proceedings of the meeting are to be published by the Food and Agriculture Organisation.

R. A. DAVIS

FUEL ECONOMY CONFERENCE OF THE WORLD POWER CONFERENCE

By DR. H. E. CROSSLEY
Fuel Research Station, Department of Scientific and Industrial Research

THE Fuel Economy Conference of the World Power Conference was opened at The Hague on September 2 by His Excellency Dr. G. W. M. Huysmans, Netherlands Minister of Economic Affairs, who was introduced by Mr. G. J. T. Bakker, chairman of the Conference. Dr. Huysmans welcomed the representatives of thirty-three countries, and told them that the critical world shortage of fuel gave additional importance to the deliberations of the Conference. It was hoped that the exchange of views on many aspects of fuel economy would be helpful to all the nations, and that the personal contacts made at the Conference would lead to collaboration in the future. The official delegates from Great Britain and France thanked the Dutch authorities for their hospitality, and looked forward to profitable discussions.

The opening speeches were followed by a lecture on "Atomic Energy for Peaceful Purposes", given by Prof. G. J. Sizoo. He pointed out that estimates of the economics of energy production by atomic fission, or of the size or nature of fission plants, are purely speculative, and often optimistic. In his opinion, atomic fission would probably become a supplementary source of energy, rather than a replacement of other sources. The alternatives of peaceful or aggressive use presented a challenge to mankind.

The first technical session of the Conference was a discussion of reports from nineteen countries on "Fuel Economy since 1939". These reports indicated the need for the direction of all fuels to the uses for which they are most suitable, to avoid many operational troubles and to provide higher efficiencies. The British report was appreciated for the account of ways by which the public have been informed of the more efficient use of fuels. A resolution was passed asking the International Executive Council of the World Power Conference, in consultation with the national committees, to consider the collection of target values for energy consumption per unit of product or effort, for discussion and publication. This resolution was later approved in principle by the International Executive Council.

Subsequent sessions were more specialized in character, as indicated by the following examples.

One session was concerned with liquid fuels, the subject of seven papers. The papers and the discussion showed the great interest in home production of liquid fuels from indigenous sources such as shale, oil sands, tar oil and wood. The commercial development of indigenous sources is, of course, dependent on the cost of imported fuels, and the quantities available for import. Dr. W. H. Zaaijer directed attention to the difficulty in several European countries of preparing motor spirit with a sufficiently high octane number, and suggested that production plants would have to be modernized to meet this demand.

In a session concerned with domestic appliances, the main subject of discussion was the desirability of having quality marks stamped on such appliances. These quality marks would be defined by standard specification of performance and design, and in consequence domestic appliances would be more efficient, and should be cheaper, due to the standardization of parts. It was felt that co-operation between appliance manufacturers and gas companies would be the best way of sponsoring advancements in the design of gas appliances. Co-operation is needed also between the gas and electricity industries, to avoid the production of undesirable appliances purely for competitive purposes.

The use of fuels for transport purposes was discussed in another session. Papers from Sweden and France showed the wastefulness of steam traction compared with electrical traction, the former requiring 2·5–3·25 times the amount of coal needed by the latter for the same load. In the United States Diesel traction is being favoured, particularly for branch line and shunting operations.

The session concerned with industrial and agricultural appliances received the largest number of contributions, twenty papers being submitted for discussion. These papers dealt with a variety of subjects, such as the use of low-grade fuels in various types of boilers and other furnace plant, the recovery of heat from waste liquors, the development of the gas turbine, and the significance of convection and radiation in heating by gas. It was stated that Britain alone had been frank in publishing operational troubles with power station boilers, and this frankness had been made possible by the collaboration of power station engineers and boiler manufacturers on the

British Boiler Availability Committee. Contacts with other countries were sought by this Committee, for the exchange of information and experience, and it was suggested that the structure of the Committee was worthy of emulation in many countries.

Four papers were submitted to the session concerned with the character of national fuel reserves, from Great Britain, Canada, the United States and France. The British contribution explained how the Coal Survey Section of the Fuel Research Organisation (Department of Scientific and Industrial Research) had helped in the production and preparation of coal, and in its storage, distribution and utilization.

Great interest was shown in the session concerned with atomic energy, although few members were able to offer contributions. It was thought possible that two kinds of fission furnace may be developed, one to use uranium 238, involving the preliminary conversion of this substance into fissile material such as plutonium, the other to use directly fissile material, such as plutonium, uranium 235 and 233. The second type of furnace would be much smaller than the first, but the material used by the first would be much more plentiful. Only 1/139 of the uranium in the earth's crust is directly fissile. If it became possible to use natural uranium, 170 tons per annum would satisfy the energy requirements of the world. Dr. W. Lulofs considered that as the world's supply of uranium would not be inexhaustible, it might be necessary to look for further sources of energy. For example, he wondered if it would be possible to build up helium from hydrogen, setting free a considerable amount of energy. Dr. J. D. Cockcroft replied that physicists had given such matters considerable thought, but with regard to the example cited, the necessary extremely high temperature is, as yet, prohibitive of progress. Several speakers considered that there had been over-optimistic views all over the world regarding the early development of atomic energy for industrial use. It is clear that many difficult problems have still to be solved before that hope can be realized; and at this stage the prospect is that atomic fission will have little, if any, financial advantage over present methods for the production of energy. It would, of course, set free very large amounts of fuels for other uses.

Other sessions considered developments in coal mining and coal preparation, economy measures in the production of gaseous fuels, the transport of gas, the transmission of electricity, and space heating. Several papers directed attention to the advantages arising from district heating in suitable towns.

The Netherlands National Committee, and an associated Committee of Ladies, arranged various technical and non-technical excursions. Facilities were provided for visits to the refineries and laboratories of the Bataafse Petroleum Maatschappij at Pernis, Delft and Amsterdam, the Philips works at Eindhoven, and the various works associated with the Netherlands State Coal Mines near Lutterade. Appreciation was expressed by all the members for the excellent organisation of the Conference and the arrangements made for the visits to works, laboratories, and places of general interest. The exchange of views and experience on the urgent question of fuel economy was felt to be most valuable and a real contribution towards the goal of economic recovery. The Conference had an even greater value in showing the benefits that can arise from a meeting of representatives of the countries of the world in a friendly spirit.

OBITUARY

Sir Albert Howard, C.I.E.

BOTANISTS, agriculturists and many others will learn with regret that Sir Albert Howard died in London on October 20. He was born in 1873 and educated at the Royal College of Science and at St. John's College, Cambridge, where he was a foundation scholar. Here he worked under Marshall Ward, who was then attracting a brilliant group of students to some of the newer aspects of botanical science, and after taking first-class honours in the Natural Science Tripos in 1898, he proceeded in 1899 to the Imperial Agricultural Department for the West Indies, then newly established with the purpose of applying science to the difficult problems raised by the threatened collapse of the sugar-growing industry there. In 1903 he returned to England to succeed F. Escombe as head of the Botanical Department of the South Eastern Agricultural College, Wye, Kent. He was not, however, entirely happy at Wye, and left in 1905 to become Imperial Economic Botanist to the Government of India, where for the first time he found full scope.

In the same year Howard married Gabrielle Louise Caroline Matthaei, of Newnham College, who was already well known for her investigations on vegetable respiration and assimilation, and they worked together for nearly twenty years at Pusa in so close a collaboration that no one knew which part was hers and which was his. Their first work was on wheat, and they were fortunate in having available an important collection of varieties brought together by W. H. Moreland and grown continuously on the Cawnpore Experimental Farm by J. Haymon, the first deputy director of agriculture, and by Bryce Burt. At that time there was a considerable export of wheat from India to England, and the Howards sought varieties giving better yields than those commonly grown, and possessing more 'strength' as defined by the English millers. Fortunately, one or both of the Howards had the artist's eye for picking out the varieties likely to do well and those that would not, and their final selections and crosses proved remarkably successful, particularly Pusa 4 and Pusa 12 in the United Provinces and the North West Frontier Province. An account of this work was given in "Wheat in India, its Production, Varieties and Improvement" (1909), and a general summary of all their work up to 1929 in "Crop Production in India" (Oxford University Press).

While at Pusa the Howards in 1912 started a Fruit Experiment Station at Quetta, a district long known for fruit-growing; it was, however, abandoned in 1919. It was re-started in 1933, but no records of the older work could be found, nor were the surviving varieties suitable for the new conditions.

In 1924 the Howards left Pusa for the new Institute of Plant Industry, Indore, established to provide a farm for Bernard Coventry, agricultural adviser to the States in Central India. The general principle underlying their administration was that the crop was to be treated as a unit and studied in relation to the field and the village; there was to be no division of the scientific work into departments. A joint book, "The Application of Science to Crop Production", was published in 1929. Unfortunately, in 1930 Mrs. Howard died, and the long and fruitful partnership came to an end. Howard himself left India in 1931; he was knighted in 1934.

At Indore, Howard had worked with Y. D. Wad on composts. These have long been known in the East, and they have the double advantage of supplying much-needed organic matter to the soil, and of affording the means of keeping the villages cleaner than would otherwise happen. No new principle was involved in the work, but his enthusiastic, even passionate, advocacy served the valuable purpose of greatly extending the use of composts. Howard, however, went further and introduced ideas regarded by scientific workers as going beyond the experimental evidence. He embodied these in two books, "An Agricultural Testament" (1940) and "Farming and Gardening for Health or Disease" (1945), and they were ably and persuasively set out in "The Earth's Green Carpet" (1947) by his second wife, Louise E. Matthaei, an associate of Newnham College and formerly chief of the Agricultural Service of the International Labour Office, Geneva. Whatever the fate of these ideas, they have caused scientific workers in agriculture to re-examine the foundations on which their hypotheses are based—always a useful exercise.

Howard was active almost to the end. For a day or two he had been slightly unwell, then came a heart attack from which he did not recover. E. JOHN RUSSELL

NEWS and VIEWS

Scientific and Technological Man-Power in Great Britain

THE report of the Committee on Scientific Man-Power (Cmd. 6824), it will be remembered (see *Nature*, June 15, p. 794, 1946), was based on the work of the Barlow Committee; both reports emphasized the vital need for increasing the output of trained men of science and technologists in Great Britain. In order that the part which universities and technical colleges will be called upon to play in this connexion may be estimated with greater accuracy than has been possible hitherto, the Advisory Council on Scientific Policy has asked for the help of the Technical and Scientific Register of the Ministry of Labour and National Service in measuring the existing man-power in the scientific and technological fields; to do this a comprehensive questionnaire is being sent out. The purpose of the survey is solely to obtain as complete an analysis as possible of the existing scientific and technological man-power in the United Kingdom and overseas in respect of its distribution in age groups between Government, industry, university and school teaching, and to use this analysis for estimating in which of the sciences it will be necessary to take special steps for increasing the output of the universities and technical colleges because of exceptionally heavy demands for home and overseas posts, previous and continuing shortages, or the high average age of any particular group. In asking for the completion of the questionnaire, the Ministry states categorically that the information provided will in no circumstances be used as a basis for any form of administrative control or direction. It is not being sought as a means of revising the Technical and Scientific Register of the Ministry of Labour.

A complementary inquiry is being conducted by the Ministry of Labour by specially appointed sub-committees of the Technical Personnel Committee presided over by Lord Hankey. These inquiries are designed to establish as nearly as possible the demands likely to be made by industry, teaching and Government service, both at home and overseas, in the various branches of science and technology during the next five to ten years, and committees have been set up to deal with chemical engineering, architecture and surveying, engineering, microbiology, entomology, geology and physics. The Committee on Chemical Engineering completed its work last year; draft reports have been prepared for architecture, surveying, microbiology and entomology; the engineering inquiry is well under way; and those into physics and geology have been commenced. It is hoped to set up a further committee in the immediate future to inquire into the future demand for chemists and metallurgists.

Committee on Science and its Social Relations

THE Committee on Science and its Social Relations, instituted by the International Council of Scientific Unions in April 1937, held its first post-war meeting in London during September 11–12. The members from the United States and from China were unable to attend, but Dr. V. Weiskopf from Cambridge, Mass., was present. A considerable part of the meeting was devoted to a discussion of the dangers facing the world from the possibilities of misusing science for war. The failure thus far to establish a world control of atomic (nuclear) energy is extremely embarrassing. Every effort towards a better understanding of the issues and dangers ahead must be supported by all means. Equally menacing dangers are connected with the possibilities of using bacteriological infections or poisons, control of which is far more difficult than that of atomic energy. It is important that those responsible for the strategy governing the armed forces of the United Nations should bear fully in mind the implications of these new weapons and of the speed with which they can be brought into operation. Equally, it is important to develop throughout the world a public opinion fully informed of the danger and strongly supporting measures leading to peace and international understanding. The whole future of the world depends on this. Much attention was also devoted to the position in which science has arrived through the legal secrecy restrictions now introduced in a number of countries; and through the support of scientific research by grants from military authorities and from industry.

The Committee decided to resume the work started before the War of making surveys of the social position of science in various countries. For this purpose the organisations adhering to the International Council (national academies and the like) will be asked to set up committees in each country to collect a number of specified data. Such a national committee, consisting of private individuals, already exists in Denmark and has done extremely valuable work there. Help will also be asked of the United Nations Educational, Scientific and Cultural

Organisation for countries not represented on the International Council; and contact will be made with the International Labour Office, the Food and Agriculture Organisation, the Economic and Social Council of the United Nations Organisation, and with the International Federation of Scientific Workers, in order to avoid duplication of work in so far as these bodies might have made inquiries of similar nature. The International Federation of Scientific Workers will also be approached concerning a charter of rights and obligations for scientific men.

Marconi Jubilee and Congress in Rome

As already recorded in *Nature* (May 3, 1947, p. 598), it is just fifty years ago that Marconi gave the first successful demonstration of wireless signalling in Great Britain. The fiftieth anniversary of the foundation of the Marconi Company was on July 20, and to mark the occasion a souvenir brochure was produced ("Jubilee Year, The Marconi Company." Pp. 58. Published by Marconi's Wireless Telegraph Co., Ltd., Chelmsford, 1947). This volume provides a brief and very interesting account of the development of wireless signalling by the Company, from the first practical transmissions over a few miles to the achievements attained in the fields of broadcasting, television and radar. The brochure is profusely illustrated by a large number of excellent photographs, many of which have a unique historical interest.

To mark the occasion of the Marconi Jubilee, the Italian National Council of Research held an International Congress in Rome during September 28–October 4. The Congress was attended by about two hundred delegates from some twelve countries: there were seven British delegates representing the Royal Society, Physical Society, Institution of Electrical Engineers, Government departments, both civil and military, and the radio industry. The technical part of the Congress comprised the presentation of a large number of scientific and technical papers describing progress in various fields of radio technique during the past twenty years or so. It is understood that these papers will be collected together and published in a special commemoration volume. Apart from one or two social events, the Congress visited the main transmitting station of the Italian Radio and Cable Co., some ten miles out of Rome. This station was extensively damaged during the War; but several long-distance short-wave circuits are now in operation. A special visit was also paid to Castel Gandolfo, at which the whole Congress was addressed by the Pope. The programme of celebrations provided the usual opportunities of meeting delegates from other countries and discussing matters of mutual interest in radio and allied fields.

Development of Insecticides and Weed-killers

TEN years ago, Plant Protection, Ltd., was formed to take over the agricultural and horticultural interests of Imperial Chemical Industries, Ltd., and Cooper, Macdougall and Robertson, Ltd., and a dinner was held recently in London to celebrate the achievements of the first decade. Replying to the toast of "Agriculture" proposed by Mr. S. W. Cheveley, managing director of the firm, Prof. Scott Watson outlined some of the remarkable advances made in recent years in the discovery and production of new insecticides and selective weed-killers. Plant Protection, Ltd., has been in the forefront of these advances. It has recruited research workers and formed an advisory service to study all aspects of the products that it markets, and give advice on how to use them. This service is international in scope. The Research Station at Fernhurst, which was taken over nearly two years ago, serves as a training centre for the technical staff as well as a research centre and demonstration centre. The Imperial Chemical Industries research stations of Hawthorndale and Jealott's Hill examine chemicals that may prove useful in plant culture, from the whole of the Imperial Chemical Industries organisation, and those that prove useful are passed on to Plant Protection, Ltd., for technical development, which is carried out at Yalding and Fernhurst. In addition, chemicals from sources outside Imperial Chemical Industries are examined and may be incorporated in the firm's range of products. Perhaps the firm's most notable contribution to the field of pest control is the production of 1,2,3,4,5,6-hexachlorocyclohexane in the 'Agrocide' range of products containing 'Gammexane'; but notable contributions have also been made to the study of plant hormones and the technique of application of seed dressings. The firm has also at its disposal the accumulated experience of Cooper, Macdougall and Robertson, Ltd., in the field of derris insecticides, a field in which they were pioneers. Plant protection is becoming, or has become, a matter for specialists, and Plant Protection, Ltd., has recognized this fact and is organising accordingly.

The Profession of Chemistry in India and Pakistan

PROF. ALEXANDER FINDLAY, past president of the Royal Institute of Chemistry, accompanied by Mrs. Findlay, is to visit important centres of scientific activity in India and Pakistan. The main purpose of his mission is to study the steps that are being and might be taken in the two Dominions to ensure that due provision will be made, and on an increasing scale, for students to receive proper training in the science of chemistry and for a fuller recognition of the status of the profession. Prof. Findlay hopes to be present at the meeting of the Indian Science Congress and the annual meeting of the Indian Section of the Royal Institute of Chemistry at Patna in January 1948, as well as at the subsequent inauguration of the examinations for the associateship of the Institute at Bangalore.

Estimated Weight of the Largest Bird

IN *The Condor* of July–August 1947 (49, No. 4), Dean Amadon gives an account of an investigation which he has made into the weight of the largest known bird. The ostrich (*Struthio camelus*), largest of living birds, was far surpassed in size by the elephant bird (*Aepyornis maximus*) of Madagascar; the larger of the New Zealand moas such as *Dinornis* were intermediate in size. The moas and elephant birds were exterminated by the natives of these islands and are known only from sub-fossil remains of skeletons, eggs and feathers. From available evidence, Amadon estimates that *Aepyornis maximus* weighed about 965 pounds and *Dinornis* about 520 pounds. This compares with a weight of about 250 pounds for the ostrich.

A Study of Cultural Phenomena

IN an article entitled "The Expansion of the Scope of Science" (*J. Washington Acad. Sci.*, 37, No. 6; June 15, 1947), Leslie A. White attempts to assess the ages and degrees of maturity of the sciences. The following 'law' is stated: "Scientific interpretation will appear to grow fastest in those areas where the determinants of human behaviour are the weakest and least significant". These determinants are least effective where the identification of the self with the external world is weakest; that is, in relation to the heavenly bodies and other inanimate objects; hence the success of astronomy, physics and chemistry. The new interpretation has then spread to the biological sciences: anatomy, physiology, psychology and sociology, in that temporal order. Dr. White regards the latest science, culturology, as in a sense superior to all the others. Many sociologists and anthropologists, for example, Ralph Linton, Robert S. Lynd and Margaret Mead, agree that the study of culture is often neglected, and approve a present tendency to study personality in its cultural background or context. But Dr. White disapproves strongly of what he calls "the exponents of 'free will' in anthropology", yet when he writes "present day anthropology is both anti-evolutionist and anti-culturological" the reader may wonder what he means by free will, evolution and culturology.

Dr. White believes that culture traits react upon each other immediately and directly. He quotes the hoe as an example. It acts upon and influences other culture traits "such as division of labour between the sexes, customs of residence, food habits, religious beliefs and ceremonies and so on". But a hoe may act upon a clod, the hoer's foot or remain unused; and to-day fashions for or against certain tools or instruments are notoriously affected by propaganda and advertising. All these are examples of human interference. We are asked to treat cultural phenomena "as if they had a life of their own". But the instances the author quotes, where "the introduction of human organisms into a consideration of these problems is not only not necessary; it is irrelevant and confusing" can be claimed as examples of problems the solution of which is impossible if the effect of human beings is excluded. Even "studies of languages on a purely linguistic, i.e., non-biological level" are sadly incomplete if one ignores the living, speaking creature. Dr. White states his belief that culture has its own laws, but for this the present article offers little evidence.

Commonwealth Fund Fellowships

The Commonwealth Fund of New York, a philanthropic foundation existing since 1918 and supported by endowment from the late Mrs. Stephen V. Harkness and the late Mr. Edward S. Harkness, has established for British subjects a number of fellowships tenable in the United States. Not more than twenty ordinary fellowships will be offered in 1948. Candidates must be of British descent, graduates of recognized universities of the British Commonwealth, and be between the ages of twenty-three and thirty-five on September 1, 1948. Not more than five service fellowships will be available for candidates of British descent who hold Government appointments overseas in the British Commonwealth. Not more than three Home Civil Service fellowships will be offered for candidates holding appointments in the Home Civil Service. None of these fellowships is open to women. There is no fixed stipend; but it is estimated at a minimum of approximately 3,500 dollars for twelve months, and is intended to cover the full expenses of residence, study and travel in the United States during the year. All applications must be submitted on the prescribed form, and must be approved by the authorities of the college or university of which the candidate is, or has been, a member. They must reach the Secretary to the Committee, Richard H. Simpson, Commonwealth Fund Fellowships, 35 Portman Square, London, W.1, by February 1, 1948.

Volcanic Activity in 1946

According to *Earthquake Notes*, **18**, Nos. 1 and 2, September 1946, the first new volcanic activity of 1946 was on February 17 when a volcano on Niuafoou in the Tonga Islands erupted violently and the lava flow partly covered a village. In the same month, in Baluchistan, a volcano north of Karachi, India, began emitting mud, and 200 miles south of Yoksuka naval base, Japan, a volcanic island rose from the sea. On March 20 Mount Sakura-Jima in southern Japan blew boulders more than 1,000 ft. into the air and sent up a smoke column 3,000 ft. high. Lava flows doomed nearby villages. On May 11 Izalco volcano in El Salvador erupted after twelve years quiescence. Santiago volcano in Nicaragua began smoking in June. On September 25 Stromboli in Italy was again active. Continued activity was reported from Kluchenskayo volcano on the Kamchatka Peninsula, which erupted in December 1944, while in New Zealand, Mount Ruapeku continued to shower dust over a wide area after the outbreak in August 1945. Paricutin volcano was intermittently active during the year, but there was an overall subsidence. Volcanic ash, reported over the Aleutian Trench in 1945, was later found to be due to a spectacular eruption on Umnak Island, which blew steam and ash several thousand feet into the air.

Chemical Composition of the Stars

A recent paper by Mr. F. Hoyle introduces some revolutionary conceptions regarding the internal constitution of the stars (*Mon. Not. Roy. Ast. Soc.*, 106, 4; 1947). Until comparatively recently it was usually assumed that the stars contain about 30 per cent of hydrogen and 10 per cent of the heavy elements; but an accumulation of observational evidence during the last fifteen years indicates that this proportion of the heavy elements is much too high. Hoyle shows that the data are more consistent with the view that, at the time of condensation of the stars, 99 per cent, and probably more than this, must have been in the form of hydrogen, the remainder consisting of heavy elements. The mean molecular weight of a star at the time of condensation must have been about 0·5, and a subsequent increase in this could arise only by the conversion of hydrogen into helium by thermonuclear reactions. In the case of small stars like the sun, very little change in composition has taken place during their life-times, so that the sun would now consist almost entirely of hydrogen. This constitution differs so widely from that of the earth, which contains very little hydrogen, that it is impossible to accept the view (now somewhat discredited) that the earth and other planets once formed part of the sun. The high ratio of hydrogen to metals in interstellar matter, obtained in 1939 by Dunham, is, Hoyle points out, a powerful argument in favour of his supernova theory of the origin of the solar system, which was developed in *Mon. Not. Roy. Astro. Soc.*, **105**, 175 (1945), and of which a short account appeared in *Nature*, **157**, 881 (1946).

The Night Sky in December

New moon occurs on Dec. 12d. 12h. 53m., U.T., and full moon on Dec. 27d. 20h. 27m. The following conjunctions with the moon take place: Dec. 3d.

14h., Saturn 4° S.; Dec. 4d. 04h., Mars 3° S.; Dec. 11d. 11h., Mercury 2° N.; Dec. 14d. 20h., Venus 3° N.; Dec. 30d. 21h., Saturn 4° S.; Dec. 31d. 23h., Mars 2° S. In addition to these conjunctions with the moon, Mercury is in conjunction with Jupiter on Dec. 15d. 02h., Mercury being 0·6° S. Mercury is a morning star throughout most of the month, rising at 6h. 04m., and 7h. 12m. at the beginning and middle of the month respectively; on Dec. 31 the planet rises 12m. after the sun. Venus, an evening star, is conspicuous in the western sky for some time after sunset as an object of stellar magnitude −3·4; about 0·9 of the illuminated portion of the apparent disk is visible during the month. Mars, in the constellation of Leo, can be seen throughout the greater portion of the night, rising at 22h. 23m., 21h. 52m., and 21h. 04m., at the beginning, middle and end of the month, respectively, and is easily recognized from its proximity to Regulus, from which it moves eastward during the month. Jupiter, in conjunction with the sun on Dec. 1, is unfavourably placed for observation until the end of the month, when it is a morning star rising about 1¾ hours before the sun. Saturn, in the constellation of Leo, is well placed for observation, rising at 21h. 46m., 20h. 50m., and 19h. 44m., at the beginning, middle and end of the month, respectively. Occultations of stars brighter than magnitude 6 are as follows: Dec. 2d. 04h. 53·2m., λ Canc. (*R*); Dec. 8d. 06h. 20·5m., *m.* Virg. (*R*); Dec. 25d. 23h. 40·2m., κ Taur. (*D*); Dec. 26d. 00h. 09·7m., υ Taur. (*D*). The times are given for Greenwich, and *D* and *R* refer to disappearance and reappearance, respectively. The Geminid meteors are active in the early part of the month; they have usually short paths and are not very bright. Winter solstice takes place on Dec. 22d. 17h.

Chemistry of Penicillin at the University of Oxford

Sir Robert Robinson writes: "In the very flattering notice published in *Nature* of November 22, p. 703, the statement is made that it was in my laboratory that the main facts of the constitution of penicillin were elucidated. This is incorrect, because many of the fundamental observations were made in the laboratory of the School of Pathology. I think a claim for 'Oxford' as a whole has been misunderstood as applying to the Dyson Perrins Laboratory. The collaboration between Drs. E. P. Abraham and E. Chain, Prof. W. Baker and myself was a close partnership, and contributions were made by both laboratories. In the summer of 1943, penicillamine was synthesized by Dr. and Mrs. J. W. Cornforth, working in the Dyson Perrins Laboratory, but independently, and in the early autumn and later, the attack developed in collaboration with other centres, especially the Imperial College of Science and Technology, in the remainder of 1943. The complex development cannot be easily summarized, but an attempt is made in Chapter 1 (*Science*, 105, No. 2739, 653; 1947) of the monograph in course of preparation."

Announcements

Dr. B. P. Dey, director of the Board of Industrial and Research Schemes in Presidency College, Madras, formerly professor of chemistry in that College, has been appointed director of the Indian institute of Science, Bangalore, in succession to Sir J. C. Ghosh, who is now director-general of industry and supply to the Government of India.

The following appointments in the University of Leeds have been announced: Dr. N. B. Slater, honorary curator of the Cecil Duncombe Observatory; Mr. J. Mars, lecturer in economics; Mr. D. Johnston, lecturer in metallurgy.

The following appointments in the University of Sheffield have been announced: H. Ferrari, lecturer in mining; Dr. W. Hume-Rothery, honorary lecturer in the Department of Metallurgy; Prof. H. N. Green, professor of pathology, granted the additional title of director of cancer research. The following resignations have been announced: G. E. Cooke, lecturer in civil engineering; Dr. H. McIlwain, lecturer in biochemistry.

The following Colonial Service appointments have been announced: J. S. Blacklock, to be agricultural officer, Sarawak; G. P. Blair, to be agricultural officer, Trinidad; M. H. Breese, to be entomologist, Nyasaland; A. J. P. Goodchild, to be entomologist, Gold Coast; J. L. Jollans, to be agricultural officer, Gold Coast; E. H. Nichols, to be agricultural officer, Sierra Leone/Gambia; W. A. Wright, to be agricultural officer, Sierra Leone/Gambia; G. E. Crichton, to be assistant conservator of forests, Sierra Leone/Gambia; Capt. P. B. Finn, to be staff surveyor, Kenya; J. B. Lyle, to be superintendent of surveys, Palestine; E. F. Martin (deputy director of agriculture, Uganda), to be deputy director of agriculture, Kenya; L. D. E. F. Vesey-Fitzgerald (entomologist, Nigeria), to be senior assistant game warden, Kenya.

A new abstract journal, described as "a monthly service of information about developments in technology and research for business men, investors, the Press, educationists and suppliers of services to industry", has appeared under the title *Facts for Industry* (A. E. Blake, Lower North Dean, Hughenden, High Wycombe, Bucks. Annual subscription, 2 guineas). Abstracts vary in length from about fifty to five hundred words, and are classified by subjects; references to original papers are quoted. The October issue consists of twelve pages including thirty-eight abstracts.

The Hungarian Academy of Sciences has started issuing the following new scientific periodicals, the papers in which are all published in English, French or German: *Hungarica Acta Mathematica*, *Hungarica Acta Physica*, *Hungarica Acta Chimica*, *Hungarica Acta Physiologica*, *Hungarica Acta Biologica*, *Hungarica Acta Medica*. Each volume consists of six fascicles of about 15–17 sheets, and the price has been fixed at 35*s.* (7 dollars, or 30 Swiss francs) per volume. The Academy would welcome the exchange of publications with other scientific institutions, in connexion with which communications should be sent to the office of the Academy, Budapest V, Akadémia-utca 2.

The Prix Arnold Reymond, provided by the Fondation Charles-Eugène Guye, is offered by the University of Lausanne for a memoir on the tendencies of scientific philosophy during the preceding ten years. The award is made at intervals of between five and ten years, the first award having been made in 1944 to Dr. Pierre Lecomte du Noüy. Memoirs to be considered for the next award, which will amount to at least 1,000 Swiss francs, must reach the Commission du Prix Arnold Reymond, Fondation Charles-Eugène Guye, Sécrétariat de l'Université, Lausanne, by January 1, 1951.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications

Blackett's Fundamental Theory of the Earth's Magnetic Field
